Author index	490

This book composes the abstracts of the presentations for the platform and poster sessions of the 25th Annual Meeting of the Society of Environmental Toxicology and Chemistry (SETAC), conducted at the International Congress Centre Barcelona (CCIB), in Barcelona, Spain from 3-7 May 2015. The abstracts are reproduced as accepted by the scientific committee of the meeting and appear in order of abstract code, in alphabetical order per presentation type. The poster spotlight abstracts are included in the list of poster abstracts. The presenting author of each abstract is underlined.

## **SOCIETY OF ENVIRONMENTAL TOXICOLOGY AND CHEMISTRY**

In the 1970s, no forum existed for interdisciplinary communication among environmental scientists—biologists, chemists, toxicologists—as well as managers and engineers others interested in environmental issues.. The Society of Environmental Toxicology and Chemistry (SETAC) was founded in North America in 1979 to fill the void. Based on the dynamic growth in the Society's membership, meeting attendance and publications, the forum was clearly needed. SETAC has two administrative offices, in Pensacola, Florida, USA, established in 1990, and in Brussels, Belgium, established in 2003.

A unique strength of SETAC is its commitment to balance the scientific interests of government, academia and business. The Society by-laws mandate equal representation from these three sectors for officers, World Council, Geographic Unit Boards of Directors and Councils, and Committee members and governance of activities. The proportion of members from each of the three sectors has remained nearly equal over the years.

SETAC publishes two globally esteemed scientific journals and convenes annual meetings around the world, showcasing cutting-edge science in poster and platform presentations. Because of its multidisciplinary approach, the scope of the science of SETAC is broader in concept and application than that of many other societies.

The Society is concerned about global environmental issues. Its members are committed to Environmental Quality through Science®, to timely and effective communication of research, and to interactions among professionals so that enhanced knowledge and increased personal exchanges occur. SETAC's growth has been marked the establishment of geographic units around the world: SETAC Europe in 1989, SETAC Asia/Pacific in 1997, SETAC Latin America in 1999 and SETAC Africa in 2012. As evidence of international acceptance of the SETAC model and of the great interest at the local level, regional chapters of the geographic units are being considered for a number of countries.

### **Publications**

Environmental Toxicology and Chemistry, an internationally acclaimed scientific journal, has grown from a quarterly publication of fewer than 400 pages annually in 1980 to a monthly publication of nearly 3,000 pages annually.

Integrated Environmental Assessment and Management, launched in 2005 to bridge the gap between scientific research and its application in environmental decision-making, regulation and management, has become a well-respected quarterly publication of 700 pages annually.

SETAC Books total more than 100, encompassing workshop results and other scientific studies.

## K1

### **Then, now.....and beyond; some personal reflections on 25 years of the Society and its science.**

Peter Calow, Office of Research, University of Nebraska-Lincoln, USA.

Having been involved in the foundation of SETAC in Europe, Peter Calow will offer a personal take on how the science has developed over the past 25 years together with some stories about his interactions with the Society and its members. One aspect of the development of the science has been a shift from concerns about reliability and repeatability to an increasing preoccupation with the somewhat elusive concept of relevance. From Sheffield to Barcelona annual meetings have embraced these issues and ensured that they have been given due attention. As we go forward and grapple with making even more of a difference for public environmental policy, the future may well invite a broader scope for our collaborations including, for example, the social sciences and economics.

## K2

### **Towards a big data-driven solution for cooperative and effective management of chemical risks**

John K. Colbourne, School of Biosciences, University of Birmingham, UK

EU lawmakers have taken the bold step of legislating the need to assess the toxicity of all chemicals sold in Europe (REACH). This has spurred science to provide a robust and cost-effective solution. However, there are huge scientific constraints in determining the environment and human health risks for an ever-increasing number and diversity of consumer products, while toxicity testing fails to keep pace with modern biology. This has created an enormous backlog of chemicals that have yet to be assessed for potential health hazards.

Considering the scale of the current problem, and realistic future projections, a shift to next-generation assays is both timely and necessary. The proposed solution is Phylogenetic Toxicology, which applies high-throughput toxicity testing with data-rich genomics assays applied to 3R compliant model species representing animal biology. These include biomedical and ecologically relevant organisms that altogether can deliver experimentally derived predictions of a chemical's modes of actions and key events in the etiology of illness or injury. This solution to chemical risk assessment incorporates an important discovery made within the past 10 years in studies of the functional elements in animal genomes; a significant suite of elements and their functional associations for growth, maintenance and reproduction is shared among animals (including humans) representing over 60% of transcribed and epigenetically modified genomes. This crucial finding is reinvigorating the use of experimental, scientifically and legally accepted biomedical alternative model species for understanding the human condition. This finding also provides a proven platform for the necessarily big and transformative set of experiments that combine genomics, metabolomics, evolutionary theory, bioinformatics and toxicology to meet the regulatory challenges of today and tomorrow.

Ultimately, the chemical safety reporting practice of tomorrow should be based on key events described within adverse outcome pathways (AOPs) and predicted to be shared with humans and other untested species using statistical and evolutionary principles. Future safety testing of chemicals will therefore be based on obtaining prescribed types of useful information, instead of following prescribed methods of satisfying regulatory requirements, which is made inexpensive by enabling technologies.

This talk is delivered on behalf of the Consortium for Environmental Omics and Toxicology..

### **Wastewater derived contaminants of emerging concern. Current and future challenges**

Mira Petrovic <sup>a, b</sup>

<sup>a</sup> Catalan Institute for Water Research (ICRA), Girona, Spain

<sup>b</sup> Catalan Institution for Research and Advanced Studies (ICREA), Barcelona, Spain

Treatment of wastewaters from domestic and industrial practices is of crucial importance in modern society. The increase in urban population, changing lifestyles and industrialization results in increase quantity of wastewater that requires treatment before it can be discharged into the aquatic environment or reused for any purpose. In parallel, the use of chemicals by our technological society is continuously growing and currently can be estimated in some hundreds of thousands of compounds (most of them organics) in daily use. Since the early 1970s municipal wastewater treatment plants (WWTP) were basically designed to remove pathogens, nutrients and organic and inorganic suspended and flocculated matter, but not microcontaminants. Since 1980, the rise of health concerns related to microcontaminants has driven the development of new treatment technology (biotic and abiotic membrane treatments, advance oxidation and reduction processes, electrochemical treatments, combined processes etc). However, in spite of a range of advanced treatment options available, at urban WWTP typically using secondary biological treatment (CAS – conventional activated sludge) not all organic contaminants are removed and discharge of treated effluents result in degraded

receiving water quality. Therefore, WWTP effluents are considered the principle route of entry of many microcontaminants into the environment. Most concerning are polar compounds that are, due to their physico-chemical properties (high water solubility and often poor degradability), able to penetrate through all natural filtration steps and man-made treatments, thus presenting a potential risk in drinking water supply. Many of these compounds originate from consumer products used in households or from industry and are generally not regulated (i.e. emerging contaminants).

This work will overview current and future challenges related with the presence of microcontaminants of emerging concern in wastewaters, such as the need to increase our knowledge about the fate of emerging microcontaminants during sewage treatment; cumbersome task of the identification of degradation products and understanding their contribution to the risk posed by emerging contaminants; risk of understudied and/or never targeted compounds; potentials and feasibility of advanced treatments; and the occurrence of emerging contaminants in environmental waters in relationship to their removal in WWTP.

## Ecological Consequences of Exposure to Pharmaceuticals (I)

1

### **Ecopharmacovigilance of human medicinal products: How it works in practice**

J.R. Snape, AstraZeneca UK Ltd. / AstraZeneca Global Environment; R. Murray-Smith, AstraZeneca; C. Coleman, AstraZeneca / Brixham Environmental Laboratory; N. Budgen, AstraZeneca / Essential Safety Health and Environment; P. Sorme, AstraZeneca / AstraZeneca Patient Safety  
Ecopharmacovigilance (EPV) is a developing science concerned with the detection, evaluation, understanding and prevention of adverse effects of active pharmaceutical ingredients (APIs) in the environment. In Europe and North America, a new regulatory submission or a line extension is normally accompanied by an Environmental Risk Assessment (ERA), but there is no regulatory requirement to monitor the environmental risks of medicines post-launch. Nevertheless, researchers globally continue to report instances of pharmaceutical residues in the environment, and publish new ecotoxicological studies on effects of pharmaceuticals on wildlife. To understand the significance of these emerging data and ensure that any potential risks are identified and managed appropriately, we have developed a process for EPV. This ensures that we can continue to understand the environmental risks associated with our products, and to manage them appropriately throughout the life of each product. This presentation will describe our EPV processes, describe how it works in practice and demonstrate some of the significant findings we have made to date.

2

### **Exploiting monitoring data in the spatial modelling of exposure of ecosystems and consumers to pharmaceuticals in the environment**

A. Boxall, University of York / Environment Department; R. Williams, Centre for Ecology and Hydrology; V. Keller, Centre for Ecology & Hydrology; S. Monteiro, APC Ltd; R. Fussell, Food and Environment Research Agency; J. Straub, F.Hoffmann-La Roche Ltd / Roche Group Safety Health Environmental Protection

In order to establish the impact of residues active pharmaceutical ingredients (APIs) in the environment on ecosystem and human health, good information on the level of exposure in surface waters and drinking waters is needed. Exposure concentrations are typically estimated using information on the usage of an API as well as removal rates in the patient, the wastewater system and in surface waters. These input data are often highly variable and difficult to obtain, so model estimates often do not agree with measurements made in the field. In this study we used an inverse modelling approach to estimate overall removal rates of pharmaceuticals at the catchment scale using a hydrological model as well as prescription and monitoring data for a few representative sites for a country or region. The overall removal rates were then used to model surface water and drinking water exposure across the broader landscape. Evaluation of this approach for APIs in surface waters across England and Wales showed good agreement between modelled exposure distributions and available monitoring data. Use of the approach, alongside estimates of predicted no-effect concentrations for the 12 study compounds, to assess risk of the APIs across the UK landscape indicated that, for most of the compounds, risks to aquatic life were low. However, ibuprofen was predicted to pose an unacceptable risk in 50% of the river reaches studied. For diclofenac, predicted exposure concentrations were also compared to the Environmental Quality Standard previously proposed by the European Commission and 4.5% of river reaches were predicted to exceed this concentration. Risks to human health were also predicted to be very low. While the current study focused on pharmaceuticals, the approach could also be valuable in assessing the risks of other 'down the drain' chemicals and could help inform our understanding of the important dissipation processes for pharmaceuticals in the pathway from the patient to ecological receptors.

3

### **Diclofenac: 40 years story of health benefits and environmental concerns. A case study on regulatory inconsistencies**

V. Acuña, RiE; A. Ginebreda, CSIC - Spanish National Research Council / Department of Environmental Sciences; M. Petrovic, ICRA; J.R. Mor, Catalan Institute for Water Research ICRA; s. sabater, Universitat de Girona; J.P. Sumpter, Brunel University / Institute for the Environment; D. Barcelo, IIQAB-CSIC / Institute for Environmental Assessment and Water Research  
Our developed technical society has been capable to design, and produce a great variety of molecular entities for improve human wellbeing. However, even the most useful and beneficial molecules might exhibit a "dark side" when placed out of its original "focus". The policies necessary to modulate such delicate balance between these opposite aspects are provided by the diverse existing regulations, but there is an increasing public perception that regulations follow a 'reactive' rather than 'proactive' behavior. The aforesaid situation can be well illustrated with the example of Diclofenac. To illustrate the two sides of this particular molecule

(effects on human wellbeing and on the environment), we reviewed the scientific literature to identify all scientific publications dealing with Diclofenac since its launch in 1975, and found that most of these publications focus on human health (81.9 %). Diclofenac has been widely used for human health purposes since the since the seventies. National annual consumptions of Diclofenac corresponding to the period 2010-2013 range from 2 to 60 Tons, and the global annual consumption was of  $1443 \pm 58$  Tons. Regarding occurrence in freshwaters, Diclofenac has been reported to occur in many freshwater ecosystems around the World, and median concentrations of the world nations averaged  $58 \pm 162$  ng L<sup>-1</sup>. The comparison of global maps of consumption and occurrence reveals that data on Diclofenac occurrence in freshwaters is poor or absent in large parts of the globe where there is consumption and most presumably occurrence in freshwaters. Molecules reaching the market are developed under the application of strict sectorial legislation (medicines, plant protection products, industrial etc.). These pieces of legislation nowadays usually take into consideration severe environmental and human health requirements as well. Contrastingly, environmental legislation is horizontal rather than sector related, and what is more relevant, it typically works "ex post". Furthermore, the time lag between the appearance of scientific evidences on harmful effects on the environment and the regulation of molecules with proven effects on human wellbeing is, in our opinion excessive if compared to the evolution of scientific knowledge, and somehow resembles the period of time elapsed from the publication of the Silent Spring, and the banning DDT worldwide.

4

### **Top-down and bottom-up effects in a diclofenac contaminated model ecosystem**

S. JOACHIM, INERIS / CIVS; R. Beaudouin, INERIS / Models for Ecotoxicology and Toxicology METO; E. Vulliet, CNRS; A. Bado-Nilles, UMRI SEBIO; G. Daniele, ISA / Equipe Traces UMR; L. Chabot, INERIS / EXES; P. Baudoin, INERIS / ECOT; O. Palluel, INERIS / Unité détoxécologie in vitro et in vivo; C. Turies, S. ANDRES, INERIS; A.R. Pery, INERIS / TOXICOLOGY AND ECOTOXICOLOGY MODELING UNIT; J. Porcher, INERIS / UMRI SEBIO  
Pharmaceuticals are widely used in human and veterinary health care products. Their occurrence in the aquatic environment is nowadays a well established issue and has become a matter of both scientific and public concern. As these substances are biologically active and might be persistent, toxic effects on organisms are suspected at low concentrations and have been demonstrated mainly for steroidal hormones. Diclofenac is a non-steroidal anti-inflammatory drug, which is found at concentrations ranging between 10- 100 µg/L in European freshwater ecosystems. As chronic ecotoxicity data as well as information on the current distribution patterns in environmental compartments are scarce, an integrated hazard assessment strategy was proposed based on low tier (standardized tests, biomarkers studies) and high tier studies (lotic mesocosms). The results of the lotic mesocosm experiment are described in this communication. The study was carried out, in twelve 20 meter long channels, under continuous, environmentally realistic concentrations of diclofenac (0.1, 1 and 10 µg L<sup>-1</sup> in triplicates). The mesocosms were set up with artificial sediments, macrophytes, periphyton, benthic and pelagic invertebrates, decomposers and one fish species (*Gasterosteus aculeatus*). After three months of ecosystem stabilization, treatment lasted 6 months. Periphyton biomass, macrophyte biovolume, zooplankton and invertebrate abundance and diversity and fish individual physiological responses along with population dynamics were the measured biological endpoints. Diclofenac concentration in water was monitored each month by chemical analysis. In order to account for the observed effects, degradation products and major metabolites were also measured in the sediment, watercress and fish. Effects on water quality parameters, macrophytes and fish were observed at the highest tested concentration. Top-down and bottom-up effects seem to drive and structure the responses of the other populations and communities. A conceptual model presenting the overall response is proposed.

5

### **Reproductive and endocrine effects of mixtures of steroidal pharmaceuticals with diverse mechanisms of action in a fish reproduction assay**

T.J. Thrupp, Brunel University / Institute for the Environment; T.J. Runnalls, Brunel University / IFE; M. Scholze, Brunel University London / Institute for the Environment; S. Kugathas, Brunel University / Institute for the Environment; A. Kortenkamp, Brunel University; J.P. Sumpter, Brunel University / Institute for the Environment

The widespread environmental occurrence of human pharmaceuticals in effluents, surface waters, seawaters and groundwater has increased concern for potential ecological effects and threats to aquatic species. Such environmental pollutants are conventionally assessed for risk on a chemical by chemical basis; however in reality aquatic organisms are exposed to a complex 'cocktail' of substances simultaneously throughout their lives. A number of synthetic steroids have been shown to have adverse effects on key biological processes of aquatic organisms at low concentrations (ng/l range), such as impairment of reproduction. Key questions for chemical risk assessment are whether steroidal pharmaceuticals can produce adverse effects on organisms when present in the environment in combination and at low concentrations, whether these can be classified as additive, and under what circumstances can they be predicted. A fish reproduction assay was used to determine reproductive and endocrine effects of five steroid pharmaceuticals. A

series of *in vivo* experiments were carried out for single steroid compounds using a well-established 21 day pair-breeding assay. Adult fathead minnows (*Pimephales promelas*) were exposed to steroidal pharmaceuticals from four different drug groups; estrogens, progestins, androgens and glucocorticoids. Each compound tested was found to decrease egg production in a concentration-dependent manner. A mixture study was subsequently designed based on mathematical modelling of single compound data. Using regression modelling and the mixture prediction models Concentration Addition (CA) and Independent Action (IA), a multicomponent mixture experiment was designed based on a fixed equipotent mixture ratio of the five compounds. Three mixture concentrations were tested in the reproduction assay. Effects of the mixture on egg production showed a clear concentration response relationship. At the lowest mixture concentration, where individual chemicals were present each at concentrations that were estimated to produce only minor effects well below the statistical detection limit of the study design, a clear combination effect was observed (ca. 40% egg reduction). The work presented here suggests that pharmaceuticals present in "real world" mixtures have the potential to act additively on certain organisational levels at low concentrations, and that combination effects should be accounted for in risk assessments.

## 6 Developmental exposure to progestins cause male bias and precocious puberty in zebrafish (*Danio rerio*)

J. Svensson, Uppsala University / Department of Environmental Toxicology; A. Mustafa, Uppsala University / Department of Comparative Physiology; I. Brandt, Uppsala University / Department of Environmental Toxicology; M. Schmitz, Uppsala University / Department of Comparative Physiology; B. Brunström, Uppsala University / Department of Environmental Toxicology  
Progestins are environmental contaminants which impair reproduction in fish at low concentrations. The mechanisms behind this effect have not been elucidated, but are likely multiple since different progestins activate not only progesterone receptors (PRs) but other steroid receptors as well. We previously showed that levonorgestrel (LNG) is a potent androgen in fish. Androgenic compounds are known to affect sexual differentiation in fish. Puberty is the process by which an animal first acquires the capability to reproduce. Puberty in fish occurs after sexual differentiation and comprises the maturation of germ cells. In zebrafish, puberty starts around 45 dpf and is marked by increased production of the gonadotropins FSH and LH. Treatment of fish with androgens is known to cause early puberty. To investigate the effects of progestins on the sexual development of fish, juvenile zebrafish were exposed to the androgenic progestin LNG and the non-androgenic progestin progesterone (P4) from 20 to 80 dpf, the critical developmental period of sexual differentiation and puberty. Expression of FSH $\beta$  and LH $\beta$  were measured at 44, 55 and 80 dpf using RT-qPCR. Sex and gonadal maturity were determined histologically at 50 and 80 dpf. At 80 dpf the sex ratio in the controls was 39% males and 61% females. At the lowest LNG concentration there was a strong bias towards males, with 96% males and 4% females. While remaining histological analyses are pending, assessment of sex based on body morphology indicated all-male populations in groups exposed to LNG  $\geq 100$  ng L $^{-1}$ . P4 did not appear to have influenced the sex ratio at any concentration. Our results show that developmental exposure of zebrafish to LNG causes nearly all-male populations at  $\geq 10$  ng L $^{-1}$ . That P4 did not appear to affect the sex ratio supports our previous contention that the androgenic progestins constitute a greater environmental risk than the non-androgenic. Both LNG and P4 caused precocious puberty, as shown by markedly higher gonadotropin expression at 44 dpf, compared with the controls. Adverse effects from early puberty are known from fish farming, including reduced growth, immunosuppression and inappropriately timed behaviors. As both LNG and P4 caused precocious puberty while only LNG affected sex ratios, effects on puberty could be mediated via PR activation. Our results indicate that progestins at close to reported environmental concentrations can severely affect sexual development in fish.

## Fish model species in environmental toxicology (I)

### 7 Use of "Omics" approach to assess adverse impact of environmentally relevant concentrations of emerging contaminants in adult fish and zebrafish embryos

H.R. Habibi, University of Calgary / Department of Biological Sciences; A. Zare, Department of Biological Sciences; J. Jordan, University of Calgary / Biological Sciences; C. Kinch, University of Calgary / Department of Biological Sciences; D.M. Kurrasch, University of Calgary / Department of Medical Genetics; A. Weljie, University of Pennsylvania / Department of Pharmacology  
Contaminants of emerging concern (CECs) are known to pose health risk to animals and humans. However, insufficient information is available about the mechanisms by which these compounds cause adverse physiological and pathological effects. We have previously observed significant increase in female to male ratio in wild populations of longnose dace caught down stream of municipalities along the Oldman River, Canada. We performed controlled laboratory experiments in which adult and embryonic fish were exposed to low, environmentally-relevant concentrations of a selected number of chemicals detected in the river system, individually and as mixtures. Physiological, morphometric, transcriptomics and

metabolomics approaches were used to investigate the mechanisms by which CECs disrupt reproduction and development in fish. Metabolomics studies demonstrate significant dysregulation of amino acid, lipid, energy, carbohydrate, nucleotide and cofactor/vitamin metabolism. Exposure of fish to mixture of chemicals resulted in relatively unique pattern of metabolism distinct from individual contaminants in gonad, liver and brain. In separate experiments, exposure of fathead minnow to environmental contaminants resulted in significant changes in transcriptome profiles, using well-characterized microarrays. We identified candidate low-dose biomarkers of chemical exposure in fish, and in combination with metabolomics data, the results provide critical information on cellular response following exposure to CECs. In zebrafish, exposure of developing embryos to contaminants resulted in precocious neurogenesis via an androgen receptor and Aromatase-B mediated mechanism, linking contaminants with altered behavior as a consequence of changes in timing of neuronal birth. The results of our studies can be used to assess risk through mechanism-based understanding of cell and tissue response. The overall results support the hypothesis that different chemicals present in the Oldman River disrupt fish health by altering gene expression profile and metabolism of the liver, ovary, testis, and brain. Use of "Omics" approach led to identification of new pathways and biological endpoints, and the findings are relevant to better understanding of the mechanisms of health impacts in fish and other vertebrate species. The authors acknowledge funding from NSERC of Canada.

### 8 "Toxicant discovery in the zebrafish:" Using zebrafish to identify novel chemicals in environmental samples

J. Legradi, Institute for Environmental Studies; X. Ouyang, Institute for Environmental Studies IVM; P. Cenijn, VU University Amsterdam / Institute for Environmental Studies; K. Kobayashi, Silicone Industry Association of Japan; C. Pylatiuk, KIT Karlsruhe Institute of Technology / Institute for Applied Computer Science; M. Lamoree, VU University, Institute for Environmental Studies / Institute for Environmental Studies; J. Legler, VU University / Institute for Environmental Studies  
Even the most sophisticated chemical analysis methods are swamped by the number of hazardous compounds found in the environment. Therefore, effect-directed analysis (EDA) was developed. EDA combines chemical analytical methods with effect related bioassays. Environmental samples are screened for biological effects in a bioassay. Positive samples are fractionated based on chemical properties and tested again in bioassays. Positive fractions are either further fractionated or chemically analyzed to identify the toxic compounds in the mixture. The identified compounds are then tested for their toxicity in the bioassay. Thereby the toxicants responsible for the effects in the mixture can be identified. Our research is focused on further developing EDA by improving the fractionation and chemical analysis as well as the bioassay to detect toxicity. Our new system called ZF-EDA combines advanced LCxLC fractionation technology with high throughput zebrafish toxicity testing. To improve the sensitivity of the bioassay detection, and to take advantage of the full potential of the zebrafish, we have extended the standard ZFET with additional more sensitive endpoints. The assays are all working within an high throughput 96 well automated format suiting EDA demands. Besides monitoring for general phenotypic malformations, cardiovascular toxicity is analyzed. The combination of endpoints allow us to screen large numbers of samples for multiple mechanisms of toxicity. Another great advantage of zebrafish in combination with EDA is the identification of substances with toxic potential *in vivo* via a high throughput pre-screen which allows for the subsequent characterization of positive fractions with more specific low throughput assays to further guide chemical detection. The ZF-EDA system was first validated using environmental standard compound mixtures. We are currently using the optimized LCxLC-UV-ToF-MS system with the extended ZFET for analysis of waste and surface water samples. Novel substances with toxic potential that are not routinely monitored within the Water Framework Directive were detected. With our approach, we have demonstrated how advanced fractionation and chemical analysis combined with high throughput zebrafish toxicity assays can be used to better detect toxic substances in environmental samples. \nAcknowledgement: The authors thank the EU FP7 EDA-EMERGE project (EU 290100) and the BE-Basic Foundation (F08.001.04, F08.002.01).

9 Characterization of a zebrafish model for acute organophosphorus poisoning  
M.D. Faria, CESAM, University of Aveiro / Biology; E. Prats, CSIC; F. Padros, FDDS Universitat Autònoma de Barcelona; P. Babin, Universités Bordeaux 1 et 2; J. Cachot, Université Bordeaux / EPOC; N. Vinas, Mississippi State University; A. Knoll-Gellida, G. Mathieu, A. Tingaud-Sequeira, MRGM-Université de Bordeaux; F. Le Bihanic, EPOC / Bat B eme etage; A.M. Soares, Universidade de Aveiro / Department of Biology and CESAM; D. Raldue, IDAEA-CSIC  
Organophosphorus (OP) compounds are currently the most commonly used pesticides in the world. Acute OP poisoning (OPP), with around 3 million cases and 300,000 deaths annually, is a major public health problem. The molecular initiating event leading to OPP is the inhibition of the acetylcholinesterase (AChE), resulting in the accumulation of the neurotransmitter acetylcholine (ACh) in the cholinergic synapses. However, the pathways conducting to some of the adverse outcomes in OPP, specially those related to the intermediate syndrome (IMS), are not

well-understood. Zebrafish is an animal model increasingly used in biomedical research, including human toxicology as well as ecotoxicology. Although the modes of action (MoA) leading to toxicity for OP pesticides in zebrafish embryos has been recently described, reported adverse pathways are more related to the developmental toxicity of OP compounds than with the OPP. In this study we use a prototypic OP compound, chlorpyrifos-oxon (CPO), to develop a zebrafish model of OPP. The acute effects of mild, moderate and high CPO concentrations on zebrafish larvae have been studied at different levels of organization including molecular (transcriptomic analysis by RNAseq, biochemical responses), cellular, tissue and organismal (gross morphology and behavioral effects [visual motor response (VMR) and touch-evoked escape response]). Three phenotypes were identified by gross-morphology and behavioral analysis. The mildest phenotype was characterized by a progressive decrease in the VMR paralleling the inhibition of the AChE activity. The second phenotype was characterized by a shortening of the trunk length and paralysis, what is consistent with the nicotinic symptoms of an acute cholinergic crisis, where the AChE inhibition results in a progressive accumulation of ACh in the neuromuscular junctions, overactivation of the nicotinic ACh receptors and overexcitation of the muscle fibers. Finally, the most severe phenotype, induced mainly by high CPO concentrations, was related to the induction of oxidative stress in the central nervous system and muscle fibers, with a strong disruption in both tissues. In conclusion, the adverse outcome pathways of the different phenotypes have been dissected empirically and the results obtained show that exposed zebrafish mimic many aspects of the human OPP, therefore allowing the use of this model for identifying new antidotes against cholinergic syndrome and IMS.

### Zebrafish embryos as a model to assess oxidative stress *in vivo*

M.M. Santos, Azti-Tecnalia / Food Quality Safety and Identity; N. Conlledo, A. Barranco, M. Pardo, S. Rainieri, AZTI tecnalia

Oxidative stress is a common mode of action of a variety of chemicals. For this reason the assessment of this endpoint is extremely important in the evaluation of the toxicity of chemical contaminants. Oxidative stress is mainly produced by the generation of Reactive Oxygen Species (ROS). These are highly reactive species with a very short half-life. For this reason their accurate and realistic detection is quite a complex issue. Most of the detection methods used for detecting ROS production and oxidative damage have been developed using *in vitro* systems. Even though such methods are useful to understand ROS cell localization and tissue damage they cannot evaluate the comprehensive effect of ROS. In fact, they cannot take into account the adaptive response and systemic signalling processes that naturally counteract basal oxy-radical production in each living organism. The complete evaluation of oxidative damage can only be accomplished with *in vivo* studies on entire organisms. In this context, the objective of this study was to establish a reliable system to determine the oxidative damage caused by environmental contaminants *in vivo*. To this end, we used zebrafish embryos and tested the oxidative damage produced by the exposure to some acknowledged pro-oxidants (*tert*-Butyl hydroperoxide) as well as inorganic and organic contaminants (arsenic, methyl mercury, polycyclic aromatic hydrocarbons, etc.). To assess the ROS production *in vivo* we used two fluorescence probes 1) 5-chloromethylfluorescein-diacetate (CMF-DA, CellTracker® Green) that detects a general oxidative stress state and 2) dihydroethidium triphenylphosphonium cation (Mito-HE, MitoSOX™ Red) that detects mainly the anion superoxide. To confirm that the ROS production caused oxidative damage we tested lipid peroxidation and cell death due to the apoptosis. The majority of the chemical tested produced significant production of ROS as well as lipid peroxidation and apoptosis indicating the formation of oxidative damage. The results obtained allowed us to establish a protocol effectively able to assess ROS production and to evaluate oxidative damage *in vivo* in a rapid and cost effective way. \n

### Investigating the developmental toxicity and molecular mechanisms of thyroid disruption in brominated flame retardant-exposed zebrafish (Danio rerio)

A. Parsons, University of Exeter / Biosciences; M. Shinichi, National Institute for Basic Biology; T. Iguchi, National Institute for Basic Biology / Molecular Environmental Endocrinology; T. Hutchinson, Centre for Environment, Fisheries, and Aquaculture Sciences (CEFAS); T. Kudoh, University of Exeter; C.R. Tyler, Biosciences College of Life and Environmental Sciences

In fish thyroid hormones mediate various developmental processes, influencing brain and skeletal development, regulating the rate of early life development and playing a key role in the events of metamorphosis. Brominated flame retardants (BFRs) are found widely in the environment and affect endocrine function principally by altering thyroid hormone homeostasis. Exposures to BFRs has been shown to disrupt circulating levels of T3 and/or T4 in rodents and fish. The molecular mechanisms underlying BFR-induced developmental toxicity and thyroid disruption are, however, still poorly understood. Though many traditional BFRs (PBDEs and HBCDs) have recently been phased out they are still widely detected in the environment. Furthermore, in order that existing fire safely regulations are met, the use of replacement BFR products (such as BTBPE and DBDPE) is increasing. These novel BFRs are similar in structure to their predecessors and are a growing concern given their potential to act as thyroid disruptors. We have developed a reporter gene assay for screening various BFRs for interactions

with zebrafish thyroid receptors (TR $\alpha$  and TR $\beta$ ). This allows us to compare the mechanistic pathways of traditional BFRs with the novel BFRs *in vitro*. Furthermore we have developed whole mount *in situ* hybridization (WISH) and qRT-PCR assays to establish the ontogeny of genes in the hypothalamus-pituitary-thyroid (HPT) axis of zebrafish embryo-larvae. We subsequently have investigated the induction/suppression of these genes upon sub-acute exposure to the thyroid hormone, triiodothyronine (T3). We have found that exposure to the T3 induces an increased expression of several thyroid related genes. For example, exposure to 30 and 100  $\mu$ g/L T3 induced a 1.4 and 1.5 fold increase in deiodinase 3 expression in 96 hours post fertilization (hpf) larvae, respectively. These data provide the fundamental underpinning for future studies to investigate the effects of BFR exposures on the thyroid axis in developing zebrafish. Keywords: thyroid, zebrafish, gene, flame-retardant

## 12

### A Temporal High-Resolution Investigation of the Ah-Receptor Cascade during Early Development of Zebrafish (Danio rerio) after PCB126 Exposure

H.A. Alert, RWTH Aachen University / Institute for Environmental Research BioV; K. Ladermann, H. Hollert, RWTH Aachen University / Institute for Environmental Research; S.H. Keiter, Orebro University / MTM Research centre The fish embryo acute toxicity test (FET) has become a well established method for the evaluation of chemicals for regulatory purposes. In addition, several studies approved the relevance and transferability of the test results to adult fish so that the FET has become a OECD guideline in 2013 (OECD 236). In addition, the FET can be used to investigate specific modes-of-action and thus is essential to understand the xenobiotic metabolism during the different life-stages of the early development of zebrafish (Danio rerio). In the present study zebrafish embryos were used to investigate the arylhydrocarbon receptor (AhR) signalling pathway in very short time intervals of 4 h from 2 h after spawning until 120 hpf. The embryos were continuously exposed to PCB 126 which is well known to be a strong inducer of the AhR pathway and still found in high concentrations in the environment. \nBy using quantitative real-time PCR we measured the expression of all genes involved in the signalling cascade of the AhR pathway. In addition, we quantified the activity of induced biotransformation enzymes under unexposed conditions as well as under the exposure of PCB 126 using a kinetic form of the EROD-assay. Together, we aim to get a more comprehensive insight of the AhR mediated metabolism at the gene expression, but also on the protein level during early life-stages of zebrafish embryos. \nqPCR mainly the cyp-genes showed a strongly increased induction of expression mediated by the AhR. A certain reduction of mRNA-levels found in the period of 60 to 88 hpf may be connected to the hatching process. They were also induced even in the absence of an AhR agonist, indicating a specific role during the early development of zebrafish. Beside the cyp-genes hsp90 $\beta$ , arnt1b, arnt1c, aip, ahr-rb and ahr2 were investigated; up to 120 hpf no alterations of their expression could be observed, whether with or without PCB126 exposure. \nEROD activity could be found already after 4 hours of exposure to PCB126. This may be due to cytochrome molecules, that have been maternally transferred into the yolk of the embryo. Until 120 h of exposure EROD activity was higher in exposed embryos than in the DMSO control. Any high variations over time could not be found. Nevertheless, even in absence of PCB126 zebrafish embryos showed clear activity of the AhR pathway, possibly due to its involvement in several developmental processes. \nThe authors thank the German Environmental Foundation (DBU). \n

## 13

### Careful with that shotgun Eugene: the challenge of inferring 18S and 16S composition from metagenomic data

A. Chariton, CSIRO Land and Water / Molecular Ecology and Toxicology; P. Greenfield, CSIRO Digital Productivity; S. Stephenson; G.C. Hose, Macquarie University / Department of Biological Sciences

High-throughput sequencing is revolutionising the way we obtain ecological data. Currently, the most common approach for obtaining DNA-diversity profiles is via the use of amplicon sequencing. While this approach is fast, relatively rapid and can capture a wide breadth of biota, artefacts associated with PCR hinder the technique's ability to obtain reliable proportional abundance data. New metagenomic methods entirely circumvent the need for PCR. Consequently, the potential to obtain unbiased proportional abundance compositional data is a tantalizing thought for many molecular ecologists. However, before we jump into routinely using metagenomic data to make assumptions about ecological condition, it is pertinent to thoroughly understand the attributes associated with metagenomic compositional data. Using a k-mer based approach, we examined 18S and 16S compositional profiles from sixty metagenomes obtained from three estuaries. DNA was sequenced using 12 lanes of Illumina HiSeq2500 (150 PE), with each sample equating to 1/5<sup>th</sup> of a lane. To examine the effect of sample depth on 16S and 18S fragment richness, an additional lane was used to resequence a single sample. The sample sequenced on a whole lane produced more than 2.93 x 10<sup>8</sup> reads, with

the same sample sequenced on 1/5<sup>th</sup> of a lane producing 5.1 x 10<sup>7</sup> (17%) reads. The increase in sampling depth increased estimates of 18S and 16S richness by capturing the rarer fragments, with the core biota remaining intact. On average, the proportion of reads which contained informative 18S fragments was very low (0.002%), with this being more than an order of magnitude greater for 16S (0.03%). As both bacteria and eukaryotes equally contributed to the metagenomes, differences in their coverage is most likely due to the relatively smaller bacterial genomes. When compared to amplicon sequencing, we found richness was far lower in the compositional data extracted from the metagenomes, with this being more pronounced in eukaryotes. Metagenome derived compositional data is complex and can provide a markedly different community profile to that obtained by amplicon sequencing. Here we not only demonstrate some of the advantages and limitations associated with both techniques, but also illustrate how these two approaches have the capacity to provide a different view of ecological condition, especially with regards to responses along natural and anthropogenic gradients.

#### 14

##### **Microcosm and shotgun proteomics to unravel individual and ecosystem responses in a long-term exposure to propranolol**

A. Campos, CIIMAR; G. Danielsson, Stockholm University / Biochemistry and Biophysics; S. Cristobal, Linköping University / Department of CI and Exp Medicine Cell Biology

Pharmaceuticals are an important group of environmental contaminants. By combining a microcosm exposure and shotgun proteomic analysis, we could study the individual and ecosystem response in a long-term exposure to propranolol. The specific goals were: i) elucidate the main molecular pathways affected by the pharmaceutical, in the Baltic Sea blue mussel, and to perform a functional analysis to the physiological response of this organism and ii) to compare the individual species response with a population response from metaproteomics analysis of Baltic soil. A 4-6 weeks microcosm experiment was conducted to study the effects of propranolol (100 or 1000 µg/L) on a Baltic Sea model community consisting of macroalgae (*Ceramium tenuicorne*), amphipods, mussels (*Mytilus edulis*) and sediment. This study enabled to observe the interference of the pharmaceutical with the inter-specific species interactions, and that mussels are the most sensitive species, showing poor condition for survival. Here we report a label-free shotgun proteomics to investigate the molecular events that underlie the physiological condition of mussels exposed to the pharmaceutical. Several mussel tissues were dissected and cytosolic, membrane and nuclei proteins fractionated by differential centrifugation. Proteins were analyzed by nano-LC-MS/MS. Protein identification was achieved by searching the MS/MS data against a customized protein sequence database which included sequences from a public repository (UniProtKB), restricted to the taxonomic group Mollusca, and sequences derived from RNA-Seq data. A metric method, based on spectral counting, was considered to evaluate the quantitative variations in protein expression. From a total of 663 proteins identified within biological replicates, 143 proteins were differentially abundant (control vs propranolol exposed groups, t-test P < 0.05). Functional classification analysis highlighted the effects of propranolol in proteins with binding, catalytic activity and structural functions. These results demonstrate the biological activity of this compound, and provide hypothesis regarding its mode of action in non-target organisms like marine mussels. By integrating data from individual species response to stressors with ecosystem response, we can explore the prediction capabilities of these methodologies and the links with adverse outcome pathways. **Keywords:** shotgun proteomics, microcosm, propranolol, mussel

#### 15

##### **Metaproteomic analysis, next generation environmental assessment in aquatic environment**

S. Cristobal, Linköping University / Department of CI and Exp Medicine Cell Biology; B. Mathew, Linköping University / Department of Clinical and Experimental Medicine Cell Biology; A. Soggiu, P. Roncada, University of Milan / Department of Veterinary Sciences and Public Health DIVET; J. Kuruvilla, Linköping University / Department of Clinical and Experimental Medicine Current metaproteomics techniques could provide a wide resolution of proteins from a complex ecosystem biological or environmental. The qualitative and quantitative metaproteomic analysis provides a functional overview over several level of complexity: at the community level, how the communities respond to the exposure, stress or disease; at the molecular level, which protein families have been expressed; and at the biochemical level, which enzymatic reaction or macromolecular machines have acquired a relevant role to maintain the community in equilibrium. Thus, metaproteomics analysis could offer a molecular snap shot of the eukaryote or prokaryote communities at a certain time and place. This alternative methodology has been applied to analyse the functional role of the microbial community in food quality, in bioremediation, characterizing how microbial species could remediate toxic metal contamination in soils and ground waters [1], in carbon cycling, defining the role that microbial species have in the flow of carbon in a given ecosystem [2], in bioenergy, by understanding how microbial species might help convert cellulosic material to biofuels [3] or most extensively in human health and personal medicine, identifying how microbial species impact/control disease vs health in organs [4, 5]. However, metaproteomic analysis has not yet explored to implement traditional environmental assessment. Environmental assessment has traditionally focussed on evaluating the

environmental quality by measuring abiotic components. The fundamental goal of a metaproteomic environmental assessment is to deliver a robust evaluation the environmental impact at population, individual, cellular and molecular level from one single, comprehensive and cost-efficient methodology. As a probe of concept, we presented the metaproteomic analysis of Baltic Sea soil exposure to propranolol for 6 weeks in a microcosm and the effects of salinity changes have also been evaluated. We tested if a metaproteomic-based assessment can estimate: i) variation in the abundance of protein families, ii) changes in biodiversity, and iii) changes in the equilibrium of a marine soil ecosystem after exposure at a stressor. **Keywords:** metaproteomics, microcosm, environmental assessment, sediment

##### **Microbial Resources Management and Omic approaches in ecotoxicology and bioremediation of polluted sites**

O. Sibourg, J. Monier, C. Baguelin, S. Entresangles, C. Malandain, ENOVEO Successful site remediation through microbial degradation requires a thorough understanding of the microbial mechanisms implicated in the biodegradation of the pollutant in question. Regardless of the nature of the pollutant or environmental matrix, the success of a bioremediation project hinges on the consideration of two essential components: the presence of a microbial community which can be stimulated in order to promote biodegradation activity and the bioavailability of the pollutant (often influenced by the chemical and physical characteristics of the site). Understanding microbial degradation processes is therefore a major contribution to the success of such projects. ENOVEO's biotechnological solutions include the characterization of the microbial degradation potential of a site and the evolution of the activity of indigenous bacteria. On-going technological advancements in the fields of metagenomics, metatranscriptomics and metaproteomics continue to bring new perspectives to our understanding of microbial mechanisms. Our presentation will illustrate how different molecular biology tools can be utilized to characterize and manage microbial resources, from the development of the remedial action plan to site treatment and closure, to identify any potential difficulties associated with up-scaling and to enable the optimization of depollution strategies.

##### **Using Next-Generation Sequencing to explore the impact of Titanium dioxide nanoparticles on the functional microbial diversity involved in soil N cycle**

M. Simonin, Microbial Ecology Lab UMR; T. Pommier, Ecologie Microbienne INRA University of Lyon; A. Dubost, CNRS University Lyon 1 / Microbial Ecology Lab UMR; J.M. Martins, LTRE University of Grenoble; A. Richaume-Jolion, Microbial Ecology Lab UMR

Titanium dioxide nanoparticles (TiO<sub>2</sub>-NPs) are commonly used in diverse manmade products, like sunscreens, toothpastes, paints or papers. Along their life cycle from production to disposal, TiO<sub>2</sub>-NPs can be released in the environment, especially the soil through various pathways, such as agricultural amendments of sewage sludge or landfills<sup>1,2</sup>. The increasing environmental release of TiO<sub>2</sub>-NPs raises concerns about the potential effect on soil functioning<sup>3</sup>. The impact of this emergent pollutant on soil nitrogen cycle was assessed on the diversity and the activity of different microbial groups involved in nitrification. In particular, we investigated how the diversity-functioning relationships are modified under this environmental pressure. A grassland soil was exposed up to 90 days to an environmentally relevant concentration or to an accidental spiking of TiO<sub>2</sub>-NPs (1 and 500 mg kg<sup>-1</sup> dry soil) in microcosms. Potential nitrification rates were measured and we used the Illumina sequencing platform (MiSeq) to explore the effects of TiO<sub>2</sub>-NPs on the diversity of total bacterial and archaeal communities (targeting 16S rRNA gene) and of two functional groups of nitrification: the ammonia-oxidizing bacteria and archaea (AOB and AOA, targeting *amoA* gene). Our results show that TiO<sub>2</sub>-NPs can alter soil nitrogen cycling, by decreasing the nitrification rates (~40%) after 90 days of exposure. Moreover, TiO<sub>2</sub>-NPs contamination altered bacterial and archaeal community structure and decreased diversity. We observed that some specific bacterial and archaeal taxa have emerged or disappeared in presence of TiO<sub>2</sub>-NPs contamination. In particular, the dominant AOA among the genus *Nitrososphaera* are strongly affected by this contaminant, with cascading negative effects on soil nitrification activity. This study highlights that archaeal communities have a key functional role in this soil. Moreover, in contrast with the general view, we show that archaea can be more sensitive to pollutants than bacteria. **References** [1] Keller AA, et al. 2013. #### 18

##### **Bactericidal effect of titanium dioxide nanoparticles: an overview of the toxicity mechanism.**

B. SOHM, S. Jomini, LIEC Université de Lorraine CNRS; F. Immel, Université de Bourgogne / UMR CNRS Biogéosciences; C. Caillet, A. Razafitianamaharavo, F. Thomas, LIEC Université de Lorraine CNRS; G. Francius, Université de Lorraine / LCPME UMR; J. Duval, LIEC Université de Lorraine CNRS; P. Bauda, LIEC UMR Université de Lorraine CNRS; C. Pagnout, Université de

Bactericidal effects of NP-TiO<sub>2</sub> under dark condition are still the subject of debate. As an example, some authors found that NP-TiO<sub>2</sub> have no effect on the laboratory model strain *E. coli* while others found for this strain EC50 values differing from 10 magnitude orders. Such contradictory results may be explained by multiple causal factors, including differences in the intrinsic characteristics of NP-TiO<sub>2</sub> and bacterial cells used in these studies, exposure conditions for toxicity assessment and even the method used to assess the toxicity, the latter being often inappropriate for nanoparticle toxicity assessment. Increasing knowledge about exposition parameters which trigger NP toxicity and associated molecular mechanisms would contribute to properly evaluate and predict NP effects/fate in the environment. In our study, analysis of the interactions between nanoparticles (NPs) and bacteria highlighted the paramount role played by interfacial electrostatic interactions (NP-cell vs. NP-NP interactions) in determining the extent of NP toxicity and the importance of physico-chemical parameters such as pH and ionic strength in controlling these interactions. In condition of interaction, we showed that nanoparticles causes *E. coli* membrane depolarization and loss of membrane integrity leading to higher cell permeability. A transcriptomic analysis highlighted that deregulated genes are involved in the response to osmotic stress, metabolism of various cell envelope components and the uptake/metabolism of other endogenous and exogenous compounds. In addition, a significant number of deregulated genes encode proteins localized in the membrane and periplasmic space. All in all, results indicate that the primary effect of NP-TiO<sub>2</sub> is initiated at the cell envelope level (membrane depolarization, loss of integrity) triggering an osmotic stress response in bacteria. These results are supported by the observed massive leakage of intracellular K<sup>+</sup>/Mg<sup>2+</sup> content concomitant with the entrance of extracellular Na<sup>+</sup>, and by the depletion of intracellular ATP level.

## Prioritization and management of multiple stressors in river basins: effects of chemical contaminants and natural stressors (I)

19

### Managing multiple stress for multiple benefits: Towards new scientific concepts, methods and tools in river basin management

S. Birk, University of Duisburg-Essen / Aquatic Ecology; D. Hering, Aquatic Ecology

Water resources globally are affected by a complex mixture of stressors resulting from a range of drivers, including urban and agricultural land use, hydropower generation and climate change. Understanding how stressors interfere and impact upon ecological status and ecosystem services is essential for developing effective River Basin Management Plans and shaping future environmental policy. This contribution details the nature of these problems for Europe's water resources and the need to find solutions at a range of spatial scales. In terms of the latter, we describe the aims and approaches of the EU-funded project MARS (Managing Aquatic ecosystems and water Resources under multiple Stress) and the conceptual and analytical framework that it is adopting to provide this knowledge, understanding and tools needed to address multiple stressors. MARS is operating at three scales: At the water body scale, the mechanistic understanding of stressor interactions and their impact upon water resources, ecological status and ecosystem services will be examined through multi-factorial experiments and the analysis of long time-series. At the river basin scale, modelling and empirical approaches will be adopted to characterise relationships between multiple stressors and ecological responses, functions, services and water resources. The effects of future land use and mitigation scenarios in 16 European river basins will be assessed. At the European scale, large-scale spatial analysis will be carried out to identify the relationships among stress intensity, ecological status and service provision, with a special focus on large transboundary rivers, lakes and fish. The project will support managers and policy makers in the practical implementation of the Water Framework Directive (WFD), of related legislation and of the Blueprint to Safeguard Europe's Water Resources by advising the 3rd River Basin Management Planning cycle, the revision of the WFD and by developing new tools for diagnosing and predicting multiple stressors.

20

### Multi-scale evaluation of multi-stressed ecosystems: an overview of a physical x chemical stressor study

S. Devin, LIEC - Université de Lorraine - CNRS / LIEC CNRS UMR; P. Bauda, LIEC UMR Université de Lorraine CNRS; J. Baudoin, French National Agency for Water and Aquatic Environments; H. Clivot, Université de Lorraine / Laboratoire Interdisciplinaire des Environnements Continentaux; C. Pagnout, Université de Lorraine; F. Colas, ECOLAB UMR CNRS UPS INPT

The proliferation of industries in the 20th century has induced a strong increase in metals inputs in rivers which have led to large-scale degradation in freshwater communities. Despite increasing severity in environmental legislation and recent decrease of metal discharges, high concentrations of metals are still present in sediments. In addition to this permanent toxic pressure, the increasing need of water has led to river hydromorphology management including an excessive dams and weirs construction. This combination of chemical and hydromorphological

stressors not only impaired local biota, but also downstream ecosystems insofar as toxicants can be transferred to other aquatic compartments. However, while those two pressures often co-occur, they are rarely considered together, and ecosystem health evaluation generally focus on either hydromorphological or chemical stress. We explored an extended battery of indicators, based upon macroinvertebrate and microbial communities, to assess modifications from the population' ecological niche to the ecosystem functioning on a total of six dams presenting a gradient of sediment contamination. Three French rivers, belonging to the same ecoregion, with two run-of-river dams on each, were selected to examine macroinvertebrates and microbial communities associated with various levels of sediment contamination. Macroinvertebrates communities were studied by surber sampling in the 10 river stations, and by a combination of dredge and surber sampling in the six reservoirs. Collected data were analysed through classical structure and composition index, and, with a functional perspective, with biological and ecological trait profiles. Microbial communities (bacteria and fungi) were investigated by PCR-DGGE to assess composition shifts according to environmental stressors, while their functional feature were described through the use of Biolog® ecoplate. Ergosterol was used as an indicator of fungal biomass. Finally, ecosystem functioning was investigated through two metrics: leaf litter decomposition and benthic fluxes at the water / sediment interface. Our study, by integrating several compartments, allow to (i) identify the ecological consequences of the interaction between hydromorphological and chemical stress in aquatic ecosystems, (ii) identify the metrics that are the most suitable to evidence either single or multiple stress and (iii) to link the biological responses to each other through a conceptual diagram.

21

### Joint and specific responses of biofilm and invertebrates to multiple stressors in Mediterranean rivers

S. Sabater, Universitat de Girona; D. Barcelo, IIQAB-CSIC / Institute for Environmental Assessment and Water Research; R. Batalla, UdL; N. De Castro, Departament d'Ecologia; A. Ginebreda, CSIC - Spanish National Research Council / Department of Environmental Sciences; M. Petrovic, ICRA; Y. Pico, University of Valencia / Medicine Preventive; L. Ponsati, E. Tornés, Catalan Institute for Water Research ICRA; I. Muñoz, University of Barcelona / Ecology  
Rivers are submitted to a variety of stressors, including nutrient and organic matter excess, physical disturbances, hydrological irregularities, and the presence of chronic concentrations of inorganic and organic pollutants. The potential interactions between these stressors difficult attribute the effects to the biota. In this study we analyze the impact of co-occurring stressors on biofilms and invertebrates in four Mediterranean river basins. Biofilms were more reactive to hydrological alterations than invertebrates, and chemical condition impairment produced an obvious impact on biological diversities and abundances in the two biological groups. Functional biomarkers (catalase activity for invertebrates, photosynthetic activity in the biofilms) evidenced the specific effect of emerging contaminants in one or the other. The presence of organic pollutants and the excess of nutrients and water conductivity were equally associated to the assemblage distribution of biofilms and invertebrates in every studied basin.

22

### Assessment of multiple stressors in 4 Iberian river basins

M. Kuzmanovic; A. Ginebreda, CSIC - Spanish National Research Council / Department of Environmental Sciences; M. Petrovic, ICRA; D. Barcelo, IIQAB-CSIC / Institute for Environmental Assessment and Water Research  
Aquatic ecosystems are exposed to multiple stressors mainly originating from anthropogenic sources. Mediterranean rivers are particularly sensitive to anthropogenic influence since they are subjected to periodic droughts, consequent flow reduction and the decrement of rivers natural dilution capacity. This natural phenomenon is expected to increase further in the future in the context of global climate change. In this study we assessed the possible stressors for each of four studied Iberian river basins (Llobregat, Ebro, Júcar and Guadalquivir) including chemical stressors as: nutrients, organic and metals pollution together with hydrological and geomorphological stressors such as flow change and dam density. The dataset was gathered in the context of the multidisciplinary project SCARCE. It included more than 200 emerging and classical pollutants both organic and metals, nutrients and biological data that were sampled at 77 sites along the 4 river basins in autumn of 2010 and 2011. Hydrological data were available from the water authorities. Chemical data were transformed into toxic units (TU) to evaluate ecotoxicological risk of the compounds by dividing the measured concentration of chemical with the corresponding toxicity threshold (for algae, invertebrates and fish). The resulting risk was mapped in GIS i.e. chemical stressors as sum of TU at each sampling site, nutrients (as concentrations) and hydrological stress. The final multiple stress risk was visualised by overlapping the individual risk maps. Multivariate statistic analysis was performed to distinguish the sites with different stress patterns. The highest overall risk was mainly in the small tributaries with the comparatively low flow and surrounded either by agricultural lands or urban zones which contributed to high input of nutrients and toxicants. Sites in the lower part of Llobregat basin (close to Barcelona area) and several in the upper area of Ebro basin (Basque Country) were mainly grouped by the characteristic urban and industrial type of pollution including pharmaceuticals, personal care products and metals. Most of the sites in the downstream part of Júcar were affected by agricultural

influence including pesticide risk and nutrient input. The overall risk and different stressors were identified for the studied river basins which could be used to prioritize the management measures to be implemented in order to improve both the chemical and ecological status.

## 23

### Environmental context influences invertebrate community responses to anthropogenic perturbations in temperate streams

F.J. Burdon, Eawag Swiss Federal Institute of Aquatic Science and Technology / Department of Aquatic Ecology; K. Räsänen; J. Jokela, Eawag / Swiss federal Institute of Aquatic Science and Technology; R.I. Eggen, Eawag / Department of Environmental Toxicology; C. Stamm, Department of Environmental Chemistry Human population growth and landuse change are contributing to increased environmental pollution, thus threatening aquatic biodiversity and ecosystem services that benefit society. Assessing pollutant impacts on the ecological integrity of receiving habitats are often based on macroinvertebrates indicators, but there is little known about the environmental factors that influence community sensitivity to perturbations such as wastewater discharges, which can have detrimental effects on the health of aquatic ecosystems. We predicted that community sensitivity would be strongly contingent upon environmental context (e.g., catchment landuses) mediated through proximate effects on upstream assemblages, as opposed to the magnitude of disturbance (e.g., wastewater dilution factors and composition), but that trait-specific indices might be more sensitive. To test our hypotheses, we sampled macroinvertebrate communities in twelve Swiss streams, with sampling reaches located above and below wastewater discharges, and assessed a variety of environmental factors at the local and catchment scale. We found that consistent with previous studies, wastewater discharges were associated with decreased alpha diversity and altered composition of macroinvertebrate communities downstream. Catchments with intensive landuses (e.g., cropping) had more pollution-tolerant assemblages, meaning that upstream community composition was a stronger determinant of total community sensitivity than the magnitude of the disturbance (e.g., wastewater discharges). In contrast, trait-specific indices were more sensitive to the effects of wastewater. In summary, wastewater influences on total invertebrate community sensitivity were context-dependent, but trait-based indices were able to discern the magnitude of wastewater disturbances against a background of environmental heterogeneity. Our findings suggest that influences at the catchment scale shape macroinvertebrate community structure, and therefore determine the stability of assemblages exposed to local disturbances such as wastewater discharges. This helps us to better appreciate the potential influences of multiple stressors in spatially heterogeneous landscapes.

## 24

### The art and science of integrating scientific knowledge for managing multiple pressures on river basins

A. Slob, TNO / Strategy Policy; I.v. Meerkerk, Erasmus University Rotterdam / Public Administration; T. Geerdink, TNO / Strategy Policy The integration of scientific knowledge for managing multiple pressures on river basins, requires an in-depth cooperation between many disciplines from social and natural sciences, like biologists, eco-toxicologists, hydrologists, geologists, economists, spatial/urban planners, sociologists, policy analysts, etc. However, interdisciplinary work is not self-executive due to epistemological differences between scientific disciplines and their different approaches. Every discipline has its own specific framing, language, routines, and ways of generating relevant and reliable knowledge. A fundamental challenge is therefore to overcome problems created by differences in disciplinary cultures: to cross the conceptual and methodological boundaries between the prevailing fields of research. We argue that integration of knowledge for river basin management requires interdisciplinary science. Interdisciplinary research is conceptualized with four dimensions: The scope or broadness of interdisciplinary research; The degree of interactive research and integration of research components; The degree of integrative understanding; Effectiveness in advancing understanding The four dimensions will be illustrated with the evaluation results of the interdisciplinary research of the FP7 ARCH-project that researches the multiple pressures on lagoons, estuaries and fjords. This project has a specific process and evaluation work package that shapes and monitors the progress of the interdisciplinary work. The following factors appeared to enhance interdisciplinary: open mindedness of the project partners, trust building between the partners, the role of facilitative leadership, the importance of developing a common vocabulary and the role of boundary objects (like joint models, maps or reports). In the ARCH project these different factors are facilitated by the project managers and are structured in the process design of the ARCH project. Furthermore, the first results of the monitoring of the interdisciplinary work in the FP7 project GLOBAQUA will be presented. The results of the ARCH-project show the specific work package facilitated and enhanced the interdisciplinary research in the project. The monitoring of the interdisciplinary work gives feedback on the progress of the interdisciplinary work. The process design is supporting the interaction between the researchers, which supports the creation of a joint vocabulary and joint learning.

### Correlating in Vitro Bioaccessibility to in Vivo Relative bioavailability for As and Pb in Housedust in China

L. Ma, Nanjing University / School of Environment; H. Li, J. Li, Nanjing University; A. Juhasz, University of South Australia / Centre for Environm. Risk Assessment & Remediation Correlating in Vitro Bioaccessibility to in Vivo Relative bioavailability for As and Pb in Housedust in China Lena Q. Ma<sup>1,2</sup>, Hong-Bo Li<sup>1</sup>, Jie Li<sup>1</sup>, & Albert L. Juhasz<sup>3</sup> <sup>1</sup>State Key Lab of Pollution Control & Resource Reuse, School of Environment, Nanjing University, Nanjing 210023, P. R. China <sup>2</sup>Soil & Water Science Dept, University of Florida, Gainesville, Florida 32611, USA <sup>3</sup>Centre for Environmental Risk Assessment & Remediation, University of South Australia, Mawson Lakes, SA 5095, Australia E-mail contact: lqma@ufl.edu Incidental ingestion of household dust is an important exposure pathway for As and Pb in children. However, compared to soils, assessment of As and Pb relative bioavailability (RBA) in housedust is limited. In this study, 24 housedust samples containing 4.48–38.2 mg kg<sup>-1</sup> As and 25.0–738 mg kg<sup>-1</sup> Pb were assessed for As and Pb bioaccessibility using the gastric (GP) and intestinal phase (IP) of the Solubility Bioaccessibility Research Consortium method (SBRC), in vitro gastrointestinal method (IVG), Deutsches Institut für Normung V. method (DIN), and physiologically based extraction test (PBET). The As and Pb RBA in 12 samples was 7.0–38 mg kg<sup>-1</sup> As and 63–738 mg kg<sup>-1</sup> Pb using a mouse blood model. Both As and Pb bioaccessibility differed significantly with in vitro assays. The SBRC with lower GP pH produced significantly higher As and Pb bioaccessibility due to enhanced As and Pb dissolution. Lead bioaccessibility values from the IP of all assays were considerably lower than the GP possibly due to Pb co-precipitation with Fe and re-adsorption onto dust matrix. However, decreased As bioaccessibility from GP to IP was only found for the SBRC and IVG. Arsenic RBA ranged from 21.8 to 85.6% with samples containing low Fe and high OC having higher As-RBA while Pb-RBA ranged from 29.1 to 60.1%. Strong in vivo–in vitro correlations (IVIVC) were found between As-RBA and As bioaccessibility for SBRC and DIN ( $r^2=0.63-0.85$ ), but weaker relationships were observed for IVG and PBET ( $r^2=0.29-0.55$ ). Similarly, Pb bioaccessibility based on the gastric phase of SBRC and DIN was correlated with Pb-RBA with  $r^2 = 0.68$  and  $0.85$ . Our data suggested that both SBRC and DINs had potential to assess As and Pb bioavailability in housedust samples. However, more research is needed to develop a valid in vitro method to predict As and Pb bioavailability in housedust.

## 26

### A correlation between nickel/metal mineralogy and its bioaccessibility in artificial (OECD) spiked soils

L. Vasiluk, University of Guelph / School of Environmental Sciences; M.D. Dutton, Vale INCO; A. Amendola, Golder Associates Ltd.; L. Van Loon, Canadian Light Source Inc; B.A. Hale, University of Guelph / School of Environmental Sciences In Ontario, Site Condition Standards for soils are based on the “total” metal concentration in soil and it is the exceedance of those that may prompt an ecological RA; therefore knowledge of a change and transformation of metals in sites that are exceeding these standards is critical. The effect of field-ageing on nickel (Ni) transformation in soil was studied using artificial OECD soils spiked with four Ni forms (NiSO<sub>4</sub>, NiO, NiS, and Ni<sub>3</sub>S<sub>2</sub>) and two Ni mixtures (NiO/Ni<sub>3</sub>S<sub>2</sub> and NiS/Ni<sub>3</sub>S<sub>2</sub>). The mineralogy of the Ni in artificial soils after ageing was characterized using XANES and Zatka sequential leaching protocol, with the goal of explaining variation in Ni bioaccessibility among soils. Total Ni recovery after wet-dry cycles designed to artificially age the soils, was variable among different Ni forms and Ni was more readily leached from soils amended with NiSO<sub>4</sub> - greater the solubility of the Ni compound, the greater the Ni leached from the soil and the poorer the total Ni recovery. The XANES spectrum for the NiO amended soil indicated that the oxide remained unaffected after ageing. In all other soil samples, the predominant Ni species were Ni<sup>2+</sup> salts and NiO. The XANES indicated that ageing resulted in an oxidation of the Ni present in the samples. Zatka leaching analysis of soils spiked with NiO alone was in a good agreement with the XANES results: NiO remained unchanged after ageing. Zatka analysis showed that Ni<sup>2+</sup> salts in the artificial soils were not soluble in the water, but soluble by ammonium citrate and most likely to be NiCO<sub>3</sub>. To evaluate the extent of bioaccessibility of Ni and its further correlation with mineralogical phase, two *in vitro* methods were used – PBET (gastric) and SBRC. Overall, Ni bioaccessibility assessed using SBRC was almost twice as high as Ni bioaccessibility using gastric PBET. Linear regression between bioaccessible Ni and ionic Ni estimated by XANES had a better correlation with SBRC values, thus likely to be more useful in discerning differences among soils. Ni “accessibility” from soil is a function of speciation, particle structure, and dissolution kinetics. Bioaccessibility simply enables adjustment of exposure estimates for risk assessment. Speciation analysis, sequential extraction provides the underlying scientific context supporting the use of bioaccessibility in risk assessment.

## 27

### Modelling arsenic and lead bioaccessibility in Canadian background soils

M. Dodd, Royal Roads University / School of Environment Sustainability; A. Rencz, P. Friske, Natural Resources Canada

Total metals in soil samples collected from over 500 locations in Canada from the surface layer (0 - 0.5 cm) and the C-horizon as part of the North American Soils Geochemical Landscapes Project indicated the concentrations of As and Pb in some of the samples exceeded the Canadian Council of Ministers of the Environment (CCME) soil quality guidelines for residential/parkland use. To obtain more information on potential health effects associated with the ingestion of contaminants associated with these soils a sub-set of the samples were analyzed for As and Pb bioaccessibility using an in vitro physiologically based extraction. The mean As and Pb concentrations were comparable to data for several uncontaminated soil types in Canada as reported by the CCME. Total Pb and bioaccessible Pb were higher in the surface layer compared to the C-horizon presumably reflecting anthropogenic inputs from historic leaded gasoline usage. Total As concentrations and bioaccessibility in the C-horizon were lower than those for the surface layer. This observation along with the regional distribution suggested that most of the As variability was controlled by the bedrock characteristics. Predictive linear regression modelling between individual bioaccessible metals (As, and Pb) and geochemical parameters such as total metals, pH, total organic carbon were conducted to ascertain the feasibility of developing a national picture of As and Pb bioaccessibility in background soils in Canada. Scatter plots and Pearson correlation indicated statistically significant negative relationship between As bioaccessibility and total As for the surface soils while P, Al and pH showed a positive relationship. The linear regression and stepwise multiple regression analyses suggested total As, P and pH were the major determinants of As bioaccessibility for the surface layer. For the C-horizon, pH and P showed positive relationship to As bioaccessibility while increasing Al and Fe concentrations decreased the bioaccessibility with P, Fe and pH as the major determinants of arsenic bioaccessibility. There were some statistically significant relationships between Pb bioaccessibility and total Pb, pH, TOC, Al, and Fe; however the modelling exercises showed total Pb, pH and TOC were the major determinants of Pb bioaccessibility for the surface layer while the total Pb and pH highly influenced Pb bioaccessibility for the surface soils. The detailed modelling and results will be presented.

#### **Implementation of a new micro profiling and micro sampling system to investigate fraction related processes at the sediment water interface**

A. Fabricius, Federal Institute of Hydrology / G aquatic chemistry; L. Duester, D. Ecker, German Federal Institute of Hydrology; T. Ternes, Bundesanstalt für Gewässerkunde

Within aquatic systems, the exchange of substances between the sediment and the overlying water is mainly driven by the steep biogeochemical gradients at the sediment water interface (SWI). The rapidly changing conditions influence the availability of nutrients, organic or inorganic analytes. To gain a better understanding of the key factors and processes determining the fate of substances at the SWI, methods with a spatial high resolution are required. The toolbox to study these heterogeneous and often dynamic environments at a spatial high resolution was considerably extended by the availability of numerous micro-sensors and -electrodes (e.g., O<sub>2</sub>, redox potential, pH value). However, the methods available for pore water sampling often require the installation of the sampling devices at the sampling site and/or intensive preparation procedures that may influence the conditions at the area studied and/or the characteristics of the samples taken. Beside the total content, questions concerning the speciation and fractionation are of interest to address the processes that govern the transport and availability of compounds at the SWI. By setting up a novel micro profiling micro sampling system ("missy") it was possible to implement for the first time a direct and automate sampling of small sample volumes (missy will be demonstrated by the results of exemplary experiments investigating trace metal(loids) distributions along depth profiles of a freshwater sediment core. Moreover, questions concerning particle driven (transport) processes will be discussed in relation to the O<sub>2</sub> concentration, redox potential and pH value measured in parallel to the pore water sampling. Besides natural processes, the technique enables to investigate (potential) effects of anthropogenic disturbances (e.g., pollutants or mechanical disturbances). Due to an increased use of engineered nanoparticles (ENPs) in numerous products and applications, they were chosen as an example for emerging substances, potentially entering aquatic systems. By investigating questions concerning (fractionation related) fate of ENPs in sediments, the benefits of the missy system in combination with different fractionation approaches will be demonstrated.

29

#### **A comparison of two techniques for quantifying [Zn<sup>2+</sup>] in estuarine waters**

H.B. Pearson, Plymouth University / SoGEES; J. Galceran, Universitat de Lleida / Departament de Química; E. Companys, Química; S. Comber, Plymouth University / Environmental Science; C.B. Braungardt, Plymouth University / School of Geography, Earth and Environmental Sciences; J. Puy, Chemistry; P. Worsfold, Plymouth University / Geography, Earth and Environmental Sciences

Keywords: Zinc; metal speciation; estuaries; analytical Zinc (Zn) is an essential element for the healthy development of all organisms, but uptake in excess can be harmful. The free metal ion is known to be the most readily biologically available and is therefore of highest concern with respect to toxicity. Zinc is now classified as

a specific pollutant by the UK Environment Agency, and changes to Environmental Quality Standards (EQS) in 2013 under the Water Framework Directive (WFD) has resulted in a revision of the standard for saline waters from 612 nM dissolved zinc to 121 nM including an ambient background concentration of 17 nM. The limited data upon which this standard is based has driven further research into methods which may be used by regulators and researchers to investigate links between metal speciation and potential biological effects. The use of the Absence of Gradients and Nernstian Equilibrium Stripping (AGNES) technique for directly determining [Zn<sup>2+</sup>] is well established for marine and low ionic strength waters, but has yet to be applied to estuarine waters, which are thought most at risk regarding compliance with new EQS. This research demonstrates, for the first time, the application of AGNES to estuarine waters from a Zn contaminated estuary in the SW of England. Data obtained from traditional complexation capacity titrations (CCT) with adsorptive cathodic stripping voltammetry (AdCSV) is compared to that directly obtained via AGNES. Water samples from the Tamar Estuary, UK have been collected over a full range of salinities (~0.1 – 35 psu) each season throughout a full calendar year. Samples were taken from locations suspected of being influenced by different ligand sources. Samples were filtered to 0.4 µm and 0.2 µm, and were analysed for DOC, nutrients, and chlorophyll-a concentrations. The total dissolved and labile Zn fraction, complexation capacity, natural ligand strengths (log Ks) and [Zn<sup>2+</sup>] have been measured. A critical comparison between the free Zn concentrations obtained from AdCSV and from AGNES has been conducted. The evolution of the different fractions of Zn (free, labile, non-labile) along the range of different salinities in the estuary is highly dependent on the season, which influences sources of ligands (both spatially and temporally), and salinity. Subsequently, seasonal variations in metal speciation should be considered when defining EQS.

30

#### **Assessing the important silver binding ligands in surface and waste water: chloride, sulphide and dissolved organic matter**

R. Nasir, Wilfrid Laurier University / Chemistry; S.D. Smith, Wilfrid Laurier University / Department of Chemistry; G. Merrington, Environment Agency; A. Peters, Wca Environment Ltd.; S. Lofts, Centre for Ecology & Hydrology / Shore Section

Silver is of particular interest due to its use in consumer products as an antimicrobial agent, leading to concerns over its unintended release into the environment. The release of silver in natural water through waste water treatment plants, as well as direct inputs, could result in increasing free metal ion concentrations and potential toxicity. Therefore, understanding the behaviour of silver as it enters aquatic systems is critical to evaluating its potential environmental risk. Developing a complete understanding of interactions between silver and strong ligands such as dissolved organic matter (DOM) and thiol compounds present in water will allow for more accurate and robust predictions of silver speciation and hence bioavailability. This project aims to better understand silver complexation with dissolved organic matter (DOM), reduced sulfide, and chloride in both waste-water and freshwater systems. DOM samples were obtained from natural waters as well as waste water effluent using a reverse osmosis system. Two reference DOM samples were also obtained from International Humic Substances Society. DOM solutions of concentrations from 50-400 mg C/L were titrated with silver using a silver ion-selective electrode (ISE) in conjunction with a Ag/AgCl reference electrode. A pH of 6, or 8 (+/- 0.5) was maintained for all solutions. The titration data was then plotted and [Ag<sup>+</sup>] calculated using the Nernst Equation. Similarly, a chloride ISE was used to determine total Chloride concentration in the DOM samples. A standard thiol assay kit was used to measure the concentration of thiol containing compounds in the samples. A three site binding model was used to model silver binding to DOM and the results were then compared to WHAM predictions and were found to be reasonably accurate for some samples. Increased binding of silver in some samples was attributed to higher concentrations of sulphur, which require further investigation. An in depth analysis of silver binding to DOM, sulphide and thiol over a range of environmental pH values and with a broader range of samples is required to gain an improved understanding of silver speciation. Ultimately the data from this research will be used to develop more accurate predictive tools for silver risk assessment and regulation in aquatic systems.

#### **Emerging contaminants of urban origin: sources, sampling, analytical issues and remediation techniques (I)**

31

#### **Can the urban fingerprint of siloxanes be characterised by their presence in different environmental matrices?**

N. Ratola, LEPAE- University of Porto / Physics of the Earth; J.A. Silva, LEPAE University of Porto; V. Homem, University of Porto / LEPABE/DEQFEUP; A. Cincinelli, Lancaster University / Chemistry Dept; P. Jimenez-Guerrero, University of Murcia / Physics; L. Santos, Faculty of Engineering - University of Porto / Chemical Engineering; A. Alves, Faculty of Engineering - University of Porto

Siloxanes have recently been identified as emerging contaminants and are now raising concern among the scientific community, due to a wide use in personal care products and cosmetics and also in industrial applications. Having high vapour

pressure, volatilization to the atmosphere is the dominant mode of emission, but their presence was reported in different environmental media. Recent reports suggest toxic effects in several organisms, but there is a general lack of information about siloxanes, with not many monitoring studies available and even fewer modelling approaches. With an emphasis on the urban fingerprint they are prone to exhibit due to their anthropogenic sources and use, this study aims to improve the knowledge of levels, trends, and behaviour of siloxanes in the environment. Adding to the incidence in the atmosphere through passive samplers (PUF disks), the assessment of the concentrations in pine needles and soil was also performed, thus closing the circle of atmospheric exposure in the areas of study. Important in the initial concept of this work was the sampling strategy, comprising different locations, which allows to distinguish between a wide range of human presences, including the cyclic behaviour of the population inflow. Hence, two sampling campaigns (one in summer and one in winter), were done in a total of 8 points in Portugal, achieving an extensive characterization of soil uses. Given the novelty of this matter, the interpretation of results is essential and requires a comprehensive approach with the use of advanced statistical validation. At the same time, modelling approaches also have to be attempted, taking into account the chemical information available on siloxanes and the decisive influence of meteorology on atmospheric movements of pollutants. Acknowledgements: This work was funded by FEDER through the Operational Programme for Competitiveness Factors – COMPETE, ON.2-O Novo Norte-North Portugal Regional Operational Programme and National Funds through FCT - Foundation for Science and Technology under the projects: PEst-C/EQB/UI0511, NORTE-07-0124-FEDER-000025 - RL2\_ Environment&Health, EXPL/AAG-MAA/0981/2013 and grant SFRH/BPD/76974/2011. #### **Biocides from façade coatings in urban surface waters: Estimating the leaching of biocides from render by polyacrylate-water partitioning constants?**

U. Bollmann, Aarhus University; K. Styszko, AGH University of Science and Technology / Dep Coal Chem Environ Science; Y. Ou, University Duisburg Essen; P. Mayer, Technical University of Denmark / Department of Environmental Engineering; S. Trapp, Danmark Tekniske Universitet / DTU Environment; J. Vollertsen, Aalborg University; K. Bester, Aarhus University / Environmental Science

Leaching of biocides from façade coatings attracts more and more attention within recent years. In-can as well as film preserving biocides are added to polymer resin based renders and paints in order to protect from microbial spoilage. However, several studies revealed that biocides leach from the façade coating and are detectable in urban stormwater runoff. The present study focussed on the occurrence of biocides in the aqueous environment - both in urban water close to the sources as well as further away in fresh and marine waters. It could be shown that biocides are ubiquitous in the aqueous environment. They are detectable not only close to their sources in stormwater run-off but also further away in marine waters with concentrations up to 60 ng L<sup>-1</sup> (mecoprop up to 200 ng L<sup>-1</sup>). Further work was done in order to estimate the leaching of biocides from building material. The possibility of using polyacrylate-water partition constants in comparison to render-water distribution constants was introduced for this purpose. The results showed that polyacrylate-water partition constants might serve as a useful and practical tool which would be closer to the reality than the commonly used water solubility and octanol-water partition constants.

33

#### **Release of benzothiazole and mercaptobenzothiazole from granules used for artificial turf**

N. Bandow, Federal Institute for Materials Research and Testing / Contaminant Transfer and Environmental Technologies; G. Güney, Beuth University of Applied Science; U. Kalbe, BAM Federal Institute for Materials Research and Testing / Contaminant Transfer and Environmental Technologies

Synthetic rubber granules and turfs are increasingly used for the construction of outdoor sport grounds. For a safe usage not only the possible impact on human health but also the risk for the environment has to be investigated. The major pathway for transferring chemicals from granules to the environment is leaching by contact with rain water. Column leaching tests are often used for determination of the leachable amount as this cannot be predicted from total solid concentrations. In earlier studies mainly release of heavy metals and regulated organic compounds as PAHs have been investigated. The measured concentrations of these compounds could not be linked to observed ecotoxicological effects. A screening of further organic compounds in the eluates revealed that mercaptobenzothiazole (MBT) is one of the major constituents. The aim of this study was thus to gain more information on leaching behavior of more polar compounds as MBT and benzothiazole (BT). Different rubber materials as styrene butadiene rubber, ethylene-propylene-diene monomer sulfur cross linked and styrenic thermoplastic elastomer were used in column percolation tests. At certain liquid to solid ratios fraction have been collected and analyzed for pH, electric conductivity, DOC and concentration of EPA-PAH, MBT and BT. Eluates were pre-concentrated using stir bar sorptive extraction (SBSE) for PAHs and for MBT/BT if necessary. The SBSE method for MBT and BT has been optimized in framework of this project. This

method is applicable for a concentration range between 10 µg/L and 1000 µg/L. Eluate concentrations of MBT and BT are rather high with concentrations not lower than 50 µg/L. The sum of the PAHs does not exceed the lower µg/L range underlining the importance of more polar compounds as MBT and BT for the environmental risk. However, it is important to note that the leaching test only gives information about the fraction which can potentially be leached. For risk assessment also the retention capacity of the soil has to be considered by geochemical modelling, which will be done in future.

34

#### **Sources and fate of several classes of emerging contaminants in a highly urbanized and industrialized area in Italy**

S. Castiglioni, Mario Negri Inst. / Environmental Health Sciences; E. Zuccato, Istituto Mario Negri; E. Davoli, Mario Negri Inst / Environmental Health Sciences

A large number of chemicals, called “emerging contaminants”, enter the environment through different pathways, are detected ubiquitously in the aquatic environment and might be of concern for humans and the environment. Most of them are discharged after human consumption or are released from manufactured products. The aim of this work was to study occurrence, sources and fate of several classes of emerging contaminants (i.e. pharmaceuticals, personal care products, disinfectants, illicit drugs, perfluorinated substances, alkylphenols) in the most urbanized and industrialized area in Italy. A mass balance of the emissions was performed to evaluate the impact of this metropolitan area in the River Lambro basin. Waste, surface and groundwater samples were solid phase extracted using mixed-mode polymeric phases and analysed by high performance liquid chromatography tandem mass spectrometry (HPLC-MS/MS). All analytical methods were validated before application, recoveries were generally higher than 80% and limits of quantifications were in the low ng/L range. Pharmaceuticals and anthropic markers were the most abundant compounds in urban wastewater and the amounts entering wastewater treatment plants (WWTPs) in the city of Milan were up to 10 kg/day. Removal rates were variable among the different classes of chemicals, they were generally higher than 70% for pharmaceuticals, illicit drugs, disinfectants, and anthropic biomarkers, but were very low for perfluorinated substances and UV filters. Removal rates were also affected by the type of advanced treatment adopted (i.e. disinfection, UV treatment) and by the nature of each substance. The levels of contaminants in surface water ranged from few ng/L to µg/L and increased continuously from north to south. The mass balance of the selected substances in the River Lambro basin showed for all the classes of contaminants additional and widespread sources other than discharges from WWTPs in Milan. Moreover, specific human or industrial sources could be identified for the different classes of compounds. Finally, groundwater resulted also affected by contamination, and the concentrations found in the first layer were higher in wells closer to rivers, suggesting a possible contribution of surface water to the contamination. The results clearly indicate that for developing remediation approaches in a highly urbanized area a complex picture made up of scattered and heterogeneous sources of contamination should be considered.

35

#### **Detection, identification, and quantification of hydroxylated isomers of bis(2-ethylhexyl)-tetrabromophthalate**

D.M. Saunders, University of Saskatchewan / Toxicology; h. peng, J. SUN, Toxicology Centre; G. Codling, University of Saskatchewan / Toxicology; S.B. Wiseman, University of Saskatchewan / Toxicology Centre; P.D. Jones, University of Saskatchewan / School of Environment and Sustainability; J.P. Giesy, University of Saskatchewan / Toxicology Center

Ultra-High Resolution LC/mass spectrometry (LC-UHRMS; Thermo Fisher Q-Exactive) was used to identify two novel isomers of hydroxylated bis(2-ethylhexyl)-tetrabromophthalate (OH-TBPH) which were unexpectedly observed in a commercial standard of bis(2-ethylhexyl)-tetrabromophthalate (TBPH). By combining UHR mass spectra (MS1), UHR-MS2 spectra and NMR analysis, the structures of the two compounds were identified as hydroxylated TBPH with a hydroxyl group on the aromatic ring. Relatively great proportions of the two isomers of OH-TBPH were detected in two technical products, Firemaster® 550 (FM-550) (0.1% and 6.2%, respectively) and Firemaster® BZ 54 (BZ-54) (0.1% and 7.9, compared to a commercial standard (0.4% and 0.9%). To simultaneously analyze OH-TBPH isomers and TBPH in dust samples, a method based on LC-UHRMS was developed to quantify OH-TBPH and TBPH using negative and positive ion modes, respectively. The instrumental limit of detection for TBPH was 0.01 µg/L, which was 200-300 times better than traditional methods (2.5 µg/L) based on gas chromatography-mass spectrometry. The analytical method combined with a Florisil cleanup was successfully applied to analyze TBPH and OH-TBPH in 23 indoor dust samples from Saskatoon, SK, Canada. Two OH-TBPH isomers, OH-TBPH1 and OH-TBPH2, were detected in 52% and 91% of dust samples, respectively. Concentrations of OH-TBPH2 (0.35±1.0 ng/g) were 10-fold greater than those of OH-TBPH1 (0.04±0.88 ng/g) in dust, similar to the profile in FM-550 and BZ-54. TBPH was also detected in 100% of samples of dust with a mean concentration of 733±0.87 ng/g. A significant (p<0.001) log-linear relationship was observed between TBPH and OH-TBPH isomers further supporting the hypothesis of a common source of emission. Relatively small proportions of OH-TBPH isomers were detected in dust (0.01%±0.67 OH-TBPH1 and 0.1%±0.60 OH-TBPH2), both of which were significantly lesser than those in

technical products ( $p < 0.001$ ). This result indicated different environmental behaviors of OH-TBPH and TBPH. Detection of OH-TBPH isomers in this study is important, since compounds with phenolic groups have often shown relatively greater toxicities than non-hydroxylated analogues. Further study is warranted to clarify the environmental behaviors and potential toxicities of OH-TBPH isomers.

### 36

#### **WASTEFFECT: Life cycle effects of emerging contaminants in waste**

N.A. Morin, Environmental Engineering; S.E. Hale, Norwegian Geotechnical Institute / Environmental Engineering; G. Okkenhaug, Norwegian Geotechnical Institute; M.M. Sparrevik; P.L. Andersson, Umea University / Chemistry Department; A.R. Almas, Norwegian University of Life Science; K. Breivik, Norwegian Inst. for Air Research; F. Wania, University of Toronto at Scarborough / Department of Physical and Environmental Sciences; G.D. Breedveld, Norwegian Geotechnical Institute / Department of Environmental Engineering; H.H. Arp, NGI / Environmental Engineering

Waste treatment has become a dynamic industrial sector, which in many countries is changing from traditional landfilling to recycling and incineration approaches that have the aim of material and energy re-capture. In addition to the issues of materials and energy recovery, waste also contains a large variety of emerging contaminants, however how landfilling, incineration, and recycling can effect environmental emissions and exposures of such emerging contaminants remains largely unexplored. WASTEFFECT is a research project funded by the Norwegian Research Council where the main goal is to develop robust waste emission and exposure models for waste regulators and companies to anticipate and reduce risks from emerging contaminants. Therefore, one of the main part of this project is to determine how emerging contaminants behave in different waste streams, including landfilling, incineration and recycling. For priority contaminants used in consumer products, waste treatment will play a large role in the ultimate removal of these substances from the environment. We have established the case study for a Norwegian waste emission inventory of legacy and new brominated flame retardants (BFRs), bisphenol A and antimony, in EE-waste, car waste, plastics, glass and combustible waste. Input parameters for these inventories have been obtained by sampling and analysing air, leachate water and solid samples from various waste treatment methods (incineration, recycling and landfilling), by considering the entire waste-life cycle. Results for bisphenol A show that a large subfraction is removed from the Norwegian environment through thermal decomposition (60%). Another subfraction is recycled (36%), and thus, not eliminated from the system. A small subfraction is "stored" in the system via landfilling (4%), though up to 20% of this deposited fraction can be introduced to the environment as water emissions or as sewage sludge used in agriculture. These data (along the ones obtained for BFRs and antimony) will be used to estimate the contribution of the waste sector to the net burden or exposure to the environment and humans. The main output of this research will help guide the waste management sector on which of the treatment methods provide the lowest risk in regards to emerging chemicals, and which processes could be optimized.

### **POPs and Pseudo-POPs: Environmental occurrence and exposure (I)**

### 37

#### **The Three Faces of P: Refocusing PBT on Exposure**

R.S. Boethling, Exposure Assessment Branch US EPA Office of Pollution Prevention and Toxics

Persistence has been defined as the ability of a chemical substance to remain in an environment in an unchanged form. The longer a chemical persists, the higher the potential for human or environmental exposure to it. Current assessment paradigms for Persistent, Bioaccumulative and Toxic (PBT) chemicals are the descendants of concerns about exposure to chlorinated pesticides (popularized in *Silent Spring*) and polychlorinated biphenyls (PCBs). "Pseudo persistence" occurs when the rate of input of a chemical exceeds rates of degradation and/or physical movement out of a given area. More important is the outcome, which is that a substance can accumulate to the point of being detectable in monitoring and/or having effects even if it is not especially resistant to molecular degradation. Here we place this in the context of a broader view of persistence, and use the flame retardant Firemaster 550 as a case study. This broader view includes molecular persistence, situational persistence and pseudo persistence, which can be called the Three Faces of P. In so doing we refocus attention on exposure assessment as the proper framework. "PBT" has come to be overused, and PBT criteria applied seemingly without thinking, because exposure assessment is difficult and PBT is simple. But this encourages simplistic and inaccurate assessment. Exposure assessment is the "more holistic" PBT paradigm that some have suggested is needed to account for the fact that substances that don't meet P half-life criteria are increasingly found in monitoring. Further, progress can be made if we expand use of models to complement other information such as half-lives. Regulators must limit "PBT" as a substitute for exposure assessment, and must be ready to endorse conclusions based in part on modeling.

### 38

#### **N-oxides - Emerging Transformation Products of Amine-containing Organic**

#### **Micropollutants**

R. Gulde, Eawag Swiss Federal Institute of Aquatic Science / Environmental Chemistry; U. Meier, Eawag Swiss federal Institute of Aquatic Science; M. Ruff, H. Singer, Eawag Aquatic Research; L. Fenner, SETAC North America  
Aliphatic amine functional groups are abundant in many pharmaceuticals and consequently chemicals containing aliphatic amines represent a significant fraction of micropollutants (MPs) present in untreated wastewater. It is therefore of interest to examine to what extent aliphatic amines are biotransformed during wastewater treatment and whether any transformation products (TPs) are formed that might be released to surface waters. We carried out biotransformation experiments with structurally diverse amine-containing compounds in activated sludge-seeded batch reactors. Samples were analyzed with a liquid chromatography high-resolution mass spectrometer and suspect and non-target screening was used to identify TPs. Aliphatic amines were found to undergo multiple biotransformation reactions, but all examined tertiary aliphatic amines formed at least an N-oxide TP. Separate batch experiments with five N-oxides further showed their biotransformation was considerably slower than that of the respective parent amines, suggesting that the formation of N-oxides during wastewater treatment could lead to significant environmental exposure to these compounds. However, hardly any information on their environmental fate or toxicity could be found. We therefore screened the effluent of a full-scale wastewater treatment plant (WWTP) for 30 wastewater-relevant MPs that contain a tertiary aliphatic amine moiety and found qualitative evidence for N-oxide formation for 10 compounds. Reference standards were purchased for seven of these N-oxides and their effluent concentrations will be determined for 10 Swiss and 4 German WWTPs. We further looked for N-oxide TPs in 11 samples along the river Rhine, that had been taken from the same parcel of water. The analytical data indicated occurrence of the N-oxide TPs of lidocaine and tramadol, and the pattern of their peak areas along the different sampling locations suggested that both the parent compound and the N-oxide TP show considerable stability in the river Rhine. The concentrations of the N-oxide TPs in these samples will be quantified to estimate the stability of the N-oxide TPs more accurately. Overall, the occurrence of N-oxide TPs in WWTP effluents and river waters points towards environmental (pseudo-)persistence of these compounds. Therefore, it will be important to also evaluate the potential for ecotoxicological effects of N-oxide TPs to fully assess their environmental risk.

### 39

#### **BROMO- AND CHLOROCARBAZOLES IN SOIL - ARE THEY POTENTIAL PERSISTENT ORGANIC POLLUTANTS?**

J. Mumbo, Helmholtz Zentrum Muenchen / Molecular EXposomics; B. Henkelmann, Helmholtz Zentrum Muenchen; G. Pfister, HMGU-MEX; K. Schramm, Helmholtz Zentrum Muenchen / Molecular EXposomics  
Carbazole, 3-chloro- and 3,6-dichlorocarbazole were detected including trichlorocarbazole not reported previously in soils. The order of concentration beginning with the highest was, 3,6-dichlorocarbazole > 3-chlorocarbazole > carbazole > trichlorocarbazole. 3,6-dichlorocarbazole recorded consistently approximately 10 times higher concentrations in comparison to carbazole and 3-chlorocarbazoles during the study period. Carbazole and 3-chlorocarbazole showed significant dissipation at 15°C but not at 20°C incubating conditions indicating that low temperature could be suitable for dissipation of carbazole and 3-chlorocarbazoles. 3,6-dichlorocarbazole was resistant at both conditions. Trichlorocarbazole however exhibited a tendency to increase in concentration with time. Pure compounds of 3-chlorocarbazole, 3,6-dibromocarbazole, and selected soil extracts exhibited EROD activity. Dioxin-like toxicity did not decrease significantly with time whereas the sum chlorocarbazole toxic equivalence concentrations did not contribute significantly to the soil assay dioxin-like toxicity equivalent concentrations. It is evident from this study that halogenated carbazoles are persistent compounds. A persistence of > 120 days recorded for carbazole and chlorocarbazoles in this study puts them in the category of potential priority PBT substances. Carbazole and 9-ethylcarbazole have been identified as a potential PBT. 9-butyl-9H-Carbazole is under investigation as high priority PBT substance. An evaluation of the less reported halogenated carbazoles but more potent compounds is required.

### 40

#### **Carbamazepine: A holistic look at its environmental persistence and fate**

J. Gan, University of California, Riverside / Department of Environmental Science; J. Li, University of California, Riverside / Department of Environmental Sciences; J.L. Conkle, Texas A&M University Corpus Christi / Physical and Environmental Sciences; X. Wu, University of California Riverside / Environmental Sciences; L. Dodgen, University of California Riverside / Environmental Science; F. Ernst, University of California Riverside / Department of Environmental Sciences  
The antiepileptic drug carbamazepine is one of the most frequently detected human pharmaceuticals in wastewater effluents and biosolids. Recent studies from this and several other groups have considered the persistence and fate of carbamazepine in soil, and its uptake and metabolism by plants. In soil, carbamazepine consistently exhibits longer persistence than many other PPCPs. For example, under aerobic conditions, the half-lives of carbamazepine in soil ranged from 1.5 to >6 months. Using <sup>14</sup>C labeling, it was shown that mineralization was negligible and carbamazepine existed largely as the parent compound in the extractable form, suggesting great mobility and bioavailability. Under hydroponic and field

conditions, carbamazepine was taken up by vegetables much more easily than many other PPCPs, and once in plants, it was readily translocated to edible tissues. In cell tissues and whole plants, carbamazepine was recalcitrant to metabolism as compared to other PPCPs. These findings together highlight that among the known PPCPs, carbamazepine may be a unique pseudo-POP in the environment and merit special attention in exposure and risk assessment.

41

#### **Substituted Diphenylamine Antioxidants (SDPA) and Benzotriazole UV Stabilizers (BZT UV) in Water, Sediment, Wastewater, and Biosolids in Canada**

A.O. De Silva, Environment Canada; D.C. Muir, Environment Canada / Aquatic Contaminants Research Division; C. Spencer, Environment Canada / Water Science Technology Directorate; T. Peart, Environment Canada; S. Smyth, Environment Canada / Water Science Technology Directorate  
An analytical method was developed to simultaneously determine substituted diphenylamine antioxidants (SDPAs) and benzotriazole UV stabilizers (BZT UVs) in liquid samples: surface water and wastewater influent and effluent using solid phase extraction and liquid chromatography tandem mass spectrometry (LCMSMS). For solid samples, sediment and biosolids, matrix dispersion liquid extraction was employed followed by LCMSMS to determine dry weight concentrations of BZT UVs and SDPAs. Five BZT-UVs were targeted including UV-328. The risk management scope for UV-328 (also known as BDTP) was published by EC in January 2014. Nine SDPAs were targeted in this study and were all part of a section 71 survey. The SDPAs are named for their alkyl substituents. Low parts per trillion levels or non-detects were observed for SDPAs and BZT-UVs in surface water from Lake Ontario, Lake Erie and other rivers and creeks. SDPAs were detected in all sediment samples in our survey. Background levels were 1.4 to 20 ng/g d.w. SDPAs in St. Clair River, Detroit River and Cootes Paradise wetland sediment. Higher concentrations of 60 ng/g were detected near a lubricating oil blending plant which was known to use SDPAs. BZT-UVs were 1-4 ng/g dw in all sediment samples and only UV328 and UV234 were detected. BZT-UVs (19-245 ng/L) and SDPAs (11-2700 ng/L) were detected in all wastewater influent samples from 9 different plants with average concentrations corresponding to 850 ng/L SDPAs and 100 ng/L BZT-UVs. Average concentrations were significantly reduced in effluent from the same plants: 48 ng/L SDPAs (0.3 ng/L – 191 ng/L) and 5 ng/L BZT-UVs (0.7 ng/L-14 ng/L). These are the first measurements of BZT-UVs in the Canadian environment and SDPAs anywhere in the world. Sediment is a major environmental compartment for SDPAs and BZT-UVs with lower concentrations and detection frequency in surface water. Sediment core analysis indicates steadily increasing deposition of two SDPAs in Lake Ontario since 1990.

42

#### **A Weight of Evidence (WOE) Approach in Analyzing Perfluorohexanoic Acid and its anion, Perfluorohexanoate, according to the Stockholm Convention POPs, Annex D Criteria**

A. Lynch, FluoroCouncil; R.C. Buck, E. I. duPont de Nemours & Co., Inc. / DuPont Chemicals and Fluoroproducts; L. Leung, DuPont CR&D; S. Shinya, Asahi Glass Co.; M. Malvasi, Solvay Specialty Polymers; J.M. Conder, Geosyntec Consultants; J.A. Arblaster, ENVIRON International Corp.

The WOE analysis evaluates the persistent organic pollutant (POP) characteristics of Perfluorohexanoic Acid (PFHxA; CAS no. 307-24-4) and its anion, Perfluorohexanoate (PFHx<sup>-</sup>), according to the Stockholm Convention Persistent Organic Pollutants (POPs), Annex D criteria (UNEP 1999, 2005), considering data from published and unpublished studies. Data indicates PFOA is stable under normal environmental conditions (Gobas, 2009; Post 2012), suggesting PFHxA is not likely to degrade. Tansiyasu et al. (2013) demonstrated that concentrations of PFHxA decreased by 0.08% after 106 days under solar irradiation in the Mt. Mauna Kea area of HI, suggesting atmospheric oxidation of PFHxA is relatively slow. Therefore, PFHxA and its anion may meet criteria for persistence in Annex D1(b)(ii). Two studies, Falandysz et al. (2007) and Llorca et al. (2012) showed in multiple species in different regions that concentrations of PFHxA existed in lower trophic levels species. At high trophic levels, no PFHxA was found, indicating no biomagnification and no bioaccumulation. Also, BCF (0.07 L/kg to < 9 L/kg) and BAF (0.02 L/kg to Researchers have detected PFHxA in urban and remote environments. Wang et al (2008) studied snow cores and showed that PFHxA was deposited as early as 1985 on the Tibetan plateau, measuring 22 pg/L whereas in 1999 levels had increased to 100 pg/L. Other researchers have measured PFHxA at levels between 10-34.5 pg/L in surface snow in Greenland (Butt, 2010). PFHxA was detected in Faroe Island sediment at 0.35 ng/g wet weight but was not detected in marine sediment in Gufunes Bay, Iceland (Butt, 2010). In addition, PFHxA was detected in seawater in the Arctic and Subarctic Canadian archipelago (Butt, 2010). All values do not meet POP criteria and therefore, indeterminate whether PFHxA meets Long Range Environmental Transport in Annex D1(d)(i). Mammalian toxicology data indicates that PFHxA is rapidly eliminated, is not a reproductive toxicant, not a neurotoxicant, and is not genotoxic or carcinogenic (Gannon, 2011, Klauig, 2014, Loveless, 2009, Chengelis, 2009, Eriksen, 2010). In conclusion, this WOE analysis adds value to the existing knowledge base of alternative chemistries being used to replace long-chain perfluoroalkyl substances.

## **Aquatic Nanotoxicology: from Freshwater to Seawater - overcoming the difficulties of standard toxicity tests and the implications for higher tier toxicity testing (I)**

43

#### **Toxicity of selected nano-objects and their aggregates and agglomerates (NOAA) to freshwater invertebrates**

V. Ricottone, Heriot-Watt University / School of Life Science; T.B. Henry, Heriot-Watt University / School of Life Sciences; V. Stone, Heriot Watt University; T.F. Fernandes, Heriot-Watt University / School of Life Sciences

This research project is funded by the European FP7 project SUN "Sustainable Nanotechnologies" which aims to address the entire lifecycle of nano-objects and their aggregates and agglomerates (NOAA) (from cradle to grave) creating an integrated approach for the long-term sustainability of nanotechnologies through the development of safe processes for production, use and end-of-life processing of nanomaterials and products, as well as methods reducing both adverse effects and exposure to acceptable levels. Aquatic exposure studies were conducted on two model species: the cladoceran *Daphnia magna* and the snail *Lymnaea stagnalis*. The experiments have started assessing the ecotoxicity on the aquatic ecosystem of prioritized pristine engineered NOAA (Org. Pig.-Red254, WC-Co, MWCNTs and CuO) among the 8 different SUN nanomaterials. The initial studies were focused on the evaluation of the acute lethal toxicity of copper oxide NPs to juveniles (7-9 day old) of the pond snail *L. stagnalis* exposed for 96h at 20°C to Cu, either in the form of CuO NPs or as aqueous salt, CuSO<sub>4</sub>\*5H<sub>2</sub>O. LC50 values estimated were, respectively, 2500 µg L<sup>-1</sup> Cu and 5.5 µg L<sup>-1</sup> Cu, indicating a greater toxicity on *L. stagnalis* of CuSO<sub>4</sub> than CuO NPs. Screening tests were conducted for the remaining prioritized nanomaterials using the crustacean *D. magna*, in order to assess the threat these NOAA might pose onto the ecosystem before proceeding with further investigations. Overall results indicate a moderate toxicity for Org. Pig.-Red254 and a much lower toxicity for the other two NOAA, WC-Co NPs, and MWCNTs. Respectively, L(E)C50 immobilization values on *D. magna* for Org. Pig.-Red254, WC-Co NPs are: 1900 µg L<sup>-1</sup> Org. Pig.-Red254, 33700 µg L<sup>-1</sup> WC-Co NPs. For MWCNTs, in the range of exposure concentrations was only possible to detect the L(E)C20 with an estimation of 9600 µg L<sup>-1</sup>. Long-term reproduction tests assessing the impact that these NOAA, their fragmented products (FP) and the weathered fragments products (WFP) may pose, based on Predicted Environment Concentration (PEC) on *L. stagnalis*, are ongoing. Endpoints, such as hatching rate, vitellogenin-like protein and quality of eggs produced by exposed snails will be evaluated.

44

#### **Influence of salinity on fate and behavior of silver-based manufactured nanomaterials and toxicity effects toward two endobenthic bivalves *Corbicula fluminea* and *Scrobicularia plana*.**

C. Bertrand, Université de Lorraine, CNRS UMR 7360; A. ZALOUK-VERGNOUX, Université de Nantes; C. Mouneyrac, Université Catholique de l'Ouest / MMS EA; I. poirier, MMS EA; a. chatel, Université Catholique de l'Ouest / Sciences Environnement; H. Perrein, Université Catholique de l'Ouest; M. Auffan, iCEINT / International Consortium for the Environmental Implications of Nanotechnology; M. Tella, CEREGE; C. Pagnout, Université de Lorraine; S. Devin, LIEC - Université de Lorraine - CNRS / LIEC CNRS UMR; L. Giamberini, Université de Lorraine, CNRS UMR 7360 / LIEC CNRS UMR  
Nano-sized silver nanoparticles (AgNPs) are extensively integrated in consumer products (e.g. textiles, wash products) because of their strong bactericidal properties. Given the relatively high production volumes of AgNPs and their potential release into the aquatic environment, assessment of the potential environmental risks of AgNPs is of high priority. While the impacts of Engineered Nanomaterials (ENMs) in freshwater media have been largely studied this last decade, data covering a salinity gradient are scarce. In this context, the "nanoSALT" research program aims to assess the fate, behaviour and toxicity effects of silver nanomaterial (AgNM) across a salinity gradient (1.5 PSU, 15.0, PSU, 30.0 PSU). Two euryhaline bivalves were selected: *Corbicula fluminea* and *Scrobicularia plana*, representative of freshwater and estuarine environments, respectively. Both species are well recognized as good models for biomonitoring purposes. These filter-feeding species may be particularly at risk of ENM exposure since they live at the interface of sediment and water column. The aim of this study was to estimate the fate and behavior of a commercial band aid containing AgNPs (Acticoat) and a selected reference AgNM (NM-300K) in water under a salinity gradient: 1.5 PSU and 15.0 PSU for *C.fluminea* and 15.0 PSU and 30.0 PSU for *S.plana* after exposition of 2 and 7 days. Salinity, pH, conductivity, oxygen levels were measured every two days. Hydrodynamic size distribution of AgNM was assessed by Dynamic Light Scattering (DLS) in exposure media. Labile forms of Ag accumulated in Diffusive Gradient Thin film (DGT) tools and Ag bioaccumulation in the digestive glands of bivalves were estimated by ICP-MS. Toxicity responses of both bivalve species were evaluated using a multi-marker approach at different levels (sub-cellular, individual) of the biological organization. First results demonstrated greater aggregation of AgNPs at high salinity (30.0 PSU) compared with 1.5 and 15.0 PSU. Burrowing behavior experiments highlighted effects of Ag ENM on both bivalve species only under feeding condition. The

feeding condition had no significant impact on *S. plana* burrowing. For *C. fluminea*, a significant increase of the burrowing kinetics was observed between the unfed and the fed conditions.

#### 45

##### **Bioaccumulation of silver and genotoxic effects in mussels *Mytilus galloprovincialis* exposed to PVP/PEI-coated silver nanoparticles through the diet at different seasons**

N. Duroudier; A. Katsumiti, University of the Basque Country UPV-EHU; A. Jimeno-Romero, University of the Basque country UPVEHU / Dep Zoology and Cell Biology Research Centre for Experimental Marine Biology and Biotechnology PIEUPVEHU; M. Mikolaczyk, J. Schafer, Université Bordeaux / UMR EPOC; E. Bilbao, University of the Basque Country (UPVEHU) / Dpt Zoology and Cell Biology; M. Cajaraville, University of the Basque country UPVEHU / Zoology and Animal Cell Biology Research Centre for Experimental Marine Biology and Biotechnology PIEUPVEHU

**Keywords:** silver nanoparticles, dietary exposure, *Mytilus galloprovincialis*, genotoxicity In the last years, silver nanoparticles (Ag NPs) have gained high commercial interest basically due to their antimicrobial properties. Applications for Ag NPs are increasing and thus, concerns about their potential input in aquatic ecosystems and their environmental hazards are also growing. Studies based on waterborne exposure have been reported, but there is a gap of knowledge on the potential toxic effects of Ag NPs ingested and transferred through the food web, especially at environmentally relevant concentrations. Further, the possibility that effects may differ depending on the season has not been explored. Therefore, dietary exposure experiments were performed with mussels *Mytilus galloprovincialis*, both in autumn and in spring, and bioaccumulation and genotoxic effects (based on Comet assay and micronuclei frequency) caused by Ag NPs were assessed at 1, 7 and 21 days. Mussels were fed daily with the microalgae *Isochrysis galbana* previously exposed for 24 hours to two different doses of PVP-PEI coated 5 nm Ag NPs: an environmentally relevant dose of 1 µg/L Ag NPs and a high dose of 10 µg/L Ag NPs (in spring) and to 10 µg/L Ag NPs (in autumn). Chemical analysis showed that microalgae exposed to 10 µg/L Ag NPs significantly accumulated Ag after 24 hours. Transmission Electron Microscopy observations evidenced electron dense deposits between the scales and the membrane of microalgae and inside cells, indicating internalization of Ag NPs in algae. Mussels fed with exposed microalgae significantly accumulated Ag after 7 and 21 days in both seasons. According to the Comet assay, both concentrations significantly damaged hemocytes DNA at 1, 7 and 21 days in spring. Micronuclei frequency showed an increasing trend after 1 and 7 days of exposure to 1 µg/L Ag NPs in spring and to 10 µg/L in both seasons, while after 21 days values returned to initial levels in all the cases. Overall, results showed a successful transfer of PVP-PEI coated 5 nm Ag NPs through the food web and significant genotoxic effects in mussels, as previously reported in several waterborne exposure studies. Moreover, the response was time- and dose-dependent. Funded by: Spanish Ministry of Economy and Competitiveness (NanoSilverOmics MAT2012-39372), Basque Government (SAIOTEK S- PEI13UN142 and Consolidated Research Group GIC IT810-13) and UPV/EHU (UFI11/37 and PhD fellowship to N.D).

#### 46

##### **Acute toxicity, bioaccumulation and effects of dietary transfer of silver from *Artemia* exposed to PVP/PEI-coated silver nanoparticles to zebrafish**

A. Fanjul, University of the Basque country UPVEHU / Dept of Zoology and Animal Cell Biology; J. Lacave, University of the Basque country (UPV/EHU); N. Gutierrez, I. Barrio, University of the Basque country UPVEHU / Department of Applied Mathematics and Operations Research; I. Arostegui, University of the Basque country UPVEHU / Department of Applied Mathematics Statistics and Operation Research; M.P. Cajaraville, A. Orbea, University of the Basque Country The continuous increase in the use of Ag nanoparticles (NPs) as consequence of their interesting commercial properties will lead to an increasing input into the ecosystems. This could lead to unforeseen health or environmental hazards. Up to date, there are few ecotoxicological studies testing the potential toxicity of Ag NPs at concentrations considered as environmentally relevant according to prediction models. Furthermore, the fate of Ag NPs in the aquatic environment is largely unknown. Silver can be bioaccumulated by lower trophic level organisms and, then, incorporated into the food chain, reaching higher level predators. Thus, in this study we have especially focused in these two aspects: (1) to test the biological effects of an environmentally relevant concentration of Ag NPs in parallel with a likely effective dose, and (2) to test bioaccumulation and effects of silver transferred by the diet. For this, the brine shrimp (*Artemia* sp.) and the vertebrate model zebrafish (*Danio rerio*) were used to simulate two trophic levels of a simplified food web. First, the acute toxicity and bioaccumulation of PVP/PEI-coated Ag NPs of 5 nm was tested in both species. Then, *Artemia* larvae exposed to Ag NPs (0.1 and 100 µg Ag/L) were used to feed zebrafish for 21 days. To study the fate and effect of silver in fish, autometallography, lysosomal membrane stability (LMS) test and histopathological analyses were applied. Ag NPs were much more toxic for zebrafish embryos (LC50 at 120 h was 50 µg Ag/L) than for *Artemia* larvae (LC50 ranging from 7.39 to 19.63 mg Ag/L depending on the exposure conditions). At the two exposure concentrations, silver bioaccumulation was detected by autometallography in the intestine and liver of fish fed with contaminated *Artemia* and this silver transfer was able to impair fish health as reflected by the reduction of

the LMS. In conclusion, in addition to being bioaccumulated and transferred through the food web, silver is able to exert toxic effects on organisms in a dose-dependent way, even at an environmentally relevant concentration, which should act as concern of the need of studies in further detail about real impact of nanomaterials in the environment and the need of usage regulations. Funded by Spanish Government (MAT2012-39372), Basque Government (IT620-13, IT810-13, Saiotek S-PEI13UN142) and UPV/EHU (UFI 11/37 and 11/52). The authors thank for technical and human support provided by SGiker of UPV/EHU.

#### 47

##### **Long-term exposure and recovery of *Lemna minor* to silver nanoparticles: the size matters**

S.P. Pereira, University of Aveiro / Depart Biologia Universidade de Aveiro; F. Jesus, University of Aveiro & CESAM / CESAM Department of Biology; S.C. Aguiar, University of Aveiro / Department of Biology; R. Oliveira, University of Brasilia / Department of Genetics and Morphology; M.A. Fernandes, CESAM & Department of Biology / department of Biology & CESAM; J.F. Ranville, Colorado School of Mines / Chemistry and Geochemistry; A.J. Nogueira, University of Aveiro / Department of Biology CESAM

The production of silver nanoparticles (AgNPs) increased exponentially in recent years, mostly due to their antibacterial properties that lead to a ubiquitous incorporation in consumer goods. This raises concerns about their environmental impact especially in aquatic systems. The AgNP's toxicity to aquatic organisms depends on several factors, including the size: smaller AgNPs are often more toxic than larger AgNPs. Scarce information regarding AgNP's effects on aquatic plants remarks the need to understand how primary producers are affected. *Lemna* sp. standard toxicity tests run along 7 days (d); thus, long-term effects (individual and sub-individual levels) of AgNPs to *Lemna minor* remain largely unknown: longer availability might occur in real environmental conditions. This study aims to answer the following questions: Which are the long-term effects of AgNPs to *L. minor*, at individual and sub-individual levels? Do long-term effects depend on AgNP's size? Do individual effects depend on exposure length? Do NP's size affect *L. minor* recovery after long-term exposure? Hence, we exposed (28d) *L. minor* to two sizes of citrate-coated AgNPs (0.02-2 mg/L) – 10 nm (10-citrate) and 80 nm (80-citrate) – in Steinberg medium (SM) and then, allowed to recover (28d) in clean SM. We assessed the effects at the individual level –relative growth rate (RGR, determined each 7d), fresh weight and phenotypic characteristics – and at the sub-individual level – the enzymatic activities of catalase (CAT), guaiacol-peroxidase (G-Pox) and glutathione-S-transferase (GST). Both AgNPs-SM solutions had dispersed NPs or small agglomerates. 10-citrate affected more *L. minor* than 80-citrate, in both exposure periods. The individual endpoints – growth inhibition and the phenotypic effects – were more pronounced at higher concentrations of AgNPs, following a dose-response curve; however, sub-individual endpoints were more sensitive. Plants succeeded to recover when exposed to low concentrations and failed when exposed to high concentrations. These effects indicate that long-term exposure to AgNPs induced the production of ROS affecting strongly the plants and inducing damage. Long-term exposure enlarges the differences between endpoints of different concentrations of AgNPs observed after 7d of exposure. Further ecotoxicological evaluations should be conducted for periods longer than 7d – OECD guideline N221.

#### 48

##### **Behaviour of TiO<sub>2</sub> nanoparticles and bulk and its toxicity in freshwater and seawater microalgae.**

M. Sendra, I. Moreno-Garrido, CSIC Spanish National Research Council; J. Blasco, Inst. Ciencias Marinas de Andalucía / Instituto de Ciencias Marinas de Andalucía

The production of manufactured nanomaterials has risen exponentially in recent years. Despite this growth, information regarding the fate and behavior of nanoparticles (NPs) in freshwater and marine aquatic ecosystem is still limited. Whiteness, opacity and being a potent photocatalyst are just some of the features that make TiO<sub>2</sub> perfect for a wide range of consumer applications such as paints, coatings, plastics, papers, printing inks, roofing granules, food, medicine, toothpaste, cosmetics and skin-care products (including topical sunscreens). Studies suggest that anatase and rutile have different photocatalytic properties, being anatase more photocatalytic than rutile. However, the mixture of both is the most photocatalytic form of them. In this research, on one hand we have used anatase/rutile NPs with particle size of ≤100 nm, while on the other hand we have used conventional or bulk TiO<sub>2</sub>. The aim of the current study was to assess the toxicity of TiO<sub>2</sub> in an aqueous solution. Two aspects were studied under laboratory conditions, I) NPs and Bulk TiO<sub>2</sub> behavior with and without microalgae and II) quantification of intracellular and extracellular NPs and Bulk TiO<sub>2</sub>. The experiment was performed for two types of microalgae *Phaeodactylum tricornutum* and *Chlamydomonas reinhardtii*, seawater and freshwater respectively. Both studies were carried out under light (UV-illumination) and white light. As regards TiO<sub>2</sub> behaviour, aggregation was accelerated by UV irradiation and ionic strength due to salinity of sea water. UV irradiation is the cause of the formation of hydroxyl groups, which change surface charge and aggregation. Moreover, the presence of algal cells affects the stability of TiO<sub>2</sub> suspensions. Both, nano and bulk TiO<sub>2</sub> formed aggregates during incubation, but NPs TiO<sub>2</sub> formed large aggregates trapped almost completely between algae more than bulk TiO<sub>2</sub> did. The dispersion

of NPs in seawater is likely to be more difficult than in freshwater. It is reasonable to assume that the mechanisms of toxicity of NPs on marine organisms are more complex. Furthermore, the trend of quantification of intracellular and extracellular TiO<sub>2</sub> was similar. Within 72 hours of interaction period under UV and white light conditions, a greater proportion of NPs TiO<sub>2</sub> was found in the supernatant compared to the surface and interior of the cell. However, the highest concentration of extracellular and intracellular TiO<sub>2</sub> showed up with NPs TiO<sub>2</sub> under UV conditions.

## Modelling of pesticides and biocides fate and exposure in a regulatory context (I)

49

### The response of EFSA to the public consultation of the draft guidance document for predicting environmental concentrations (PECs) in soil

A. Tiktak, Water Agriculture and Food; J. Boesten, Alterra / ERA team; M. Egmsø, EFSA; S. Karlsson, Swedish Chemicals Agency KEMI; M. Klein, Fraunhofer IME; M. Stemmer, Austrian Agency for Health and Food Safety / Institute for Plant Protection Products

In July 2014, EFSA launched an open consultation on the draft guidance document for predicting environmental concentrations of plant protection products (PPPs) in soil. This EFSA Guidance Document is intended to be used by applicants and authorities in the context of the review of PPPs under Regulation (EC) 1107/2009. Guidance is provided for all types of concentrations of active substances and metabolites of these substances that are potentially needed for assessing ecotoxicological effects to soil organisms, i.e. the concentration in total soil and the concentration in pore water. The procedure consists of five tiers; the first three tiers are described in the guidance document. User-friendly software was developed to facilitate consistent and efficient use of the tiered approach in regulatory practice. EFSA received some 300 comments from regulators, industry, research institutes and consultants. This has resulted in an update of the guidance document and will result in an update of the software tools. In this presentation, we will briefly summarise the Guidance Document and then discuss the most important changes that have been made in response to stakeholder's comments.

### The new TOXSWA 4.4.2: Impact within the regulatory context of pesticide authorization in the EU

W. Reiher,

A new version of the FOCUS surface water model TOXSWA 4.4.2 – used within the regulatory process of pesticide authorization in Europe – addresses formation of metabolites in water and sediment. As a consequence the lower tier STEP 1-2 tool was adapted as well providing predicted environmental concentrations (PEC) of aquatic metabolites to be in a reasonable order (Step 1 > Step 2 > Step 3). At Step 3 of the FOCUS surface water assessment, PECs are in principle calculated for the three different water bodies ditches, streams and ponds. Since for streams parent input from upstream catchment is taken into account within the FOCUS scenario setup a procedure addressing aquatic formation of metabolites in the upstream catchment was developed as well. Therefore, so-called correction factors were introduced, taking into account transformation rate of parent and metabolite referenced to average temperature of the water layer, formation fraction of metabolite as well as conservative assumptions on the average residence time in upstream catchment, i.e. the time available for degradation of a metabolite formed in the upstream catchment. Extensive simulations were calculated with old and new FOCUS sw tools (STEP 1-2, TOXSWA) considering three different parent compounds combined with nine different primary metabolites each for all drainage and runoff scenarios parameterized for four FOCUS crops in total. Results show that the new approach may result in considerably higher new PEC<sub>sw</sub> global max values for aquatic metabolites compared to a workaround described in the FOCUS surface water guidance from 2001 which also leads to higher base concentrations and increased time weighted average concentrations of aquatic metabolites. It is expected that in future Step 3 calculations for aquatic metabolites are required more frequently. The implemented procedure on addressing aquatic formation of metabolites in upstream catchment may lead to over-conservative high concentrations; the conservative nature of this approach is useful for representing a realistic worst-case whereas at the same time the simplifications of the approach demonstrate that further refinement option should be developed. Some potential refinement options will be stated.

51

### GERDA - GEObased [German] Runoff, erosion and Drainage risk Assessment

D. Grossmann; M. Bach, University of Giessen; M. Diesner, German Federal Environment Agency UBA; D. Guerniche, RLP AgroScience GmbH; U. Hommen, M. Klein, Fraunhofer IME; R. Kubiak, RLP AgroScience; A. Mueller, Federal Environment Agency / IV; J. Priegnitz, Umweltbundesamt / FG IV Pflanzenschutzmittel; S. Reichenberger, FOOTWAYS SAS; K. Thomas, Institute for Agroecology; M. Trapp, RLP AgroScience, IfA / Institute for Agroecology For the EU approval of the active substance the model FOCUS Surface Water was established based on the principle “one safe use” in Europe. Although FOCUS Surface Water has been used for regulatory decision making the overall level of protection is not clear. That includes in particular the level of representativeness of

the FOCUS Surface Water scenarios for the national specific agro-environmental conditions. To answer this question for the national authorisation in Germany as well as to adjust the German national exposure and risk assessment procedure to the FOCUS Surface Water approach in the harmonisation spirit of regulation (EC) 1107/2009 and furthermore to enhance some of the limitations of FOCUS Surface Water the German Federal Environment Agency (UBA) has launched in 2011 a research project to develop GERDA (Geobased [German] Runoff, Erosion, and Drainage risk Assessment). GERDA will replace the currently used model EXPOSIT to evaluate the surface water exposure from PPP input by runoff, erosion and drainage in future. The FOCUS based but nationally specified exposure assessment approach might be applicable to EU member states. Long-term PEC time series (30 years) for surface water and sediment are calculated, in contrast to only 12 or 16 months in FOCUS<sub>sw</sub>. Edge-of-field pesticide loss is still calculated by PRZM and MACRO but instead of TOXSWA, GERDA uses the model STEPS-1-2-3-4 to calculate PEC hourly time series in the receiving water body. To select a reliable soil-climate scenarios PRZM and MACRO simulation runs for soil/climate/crop/substance-combinations, covering the entire agricultural land area (arable and permanent crops) are used to calculate long-term PEC<sub>sw</sub> time series. The time series are ranked according to the calculated PEC<sub>sw</sub> to create area-weighted CDFs. The level of protection of the exposure endpoint (PEC) will be known. For Germany GERDA calculations are based on a combination of 80th spatial / 80th temporal percentile for national specific soil-climate-scenario leading to an “overall” (approx.) 90th centile level of protection. Details on the concept and the main components have already been presented. GERDA runs on 13 test compounds demonstrate that GERDA generally leads to the same regulatory decision as the current national exposure assessment. In some cases the regulatory decision with GERDA would be more conservative when risk mitigation options are respected.

52

### How representative are the Northern groundwater scenarios to the actual conditions in the Northern Zone?

A. Gimsing, The Danish Environmental Protection Agency / Pesticides and Gentechology; M. Burns, S. Reichenberger, FOOTWAYS SAS; L. Zaroni, H. Tripault, Footways SAS; P. Mulder, The Norwegian Food Safety Authority; H. Lützhøft, Technical University of Denmark / Department of Environmental Engineering; D. Kavaliauskaite, The State Plant Service under the Ministry of Agriculture; J. Asp, P. Åhrlin, Swedish Chemicals Agency; L. Mattsoff, Finnish Safety and Chemicals Agency (Tukes) / Chemical Products Surveillance; K. Kruskops, State Plant Protection Service Latvia

Regulatory pesticide risk assessments for groundwater in the Northern Zone currently rely on the use of a limited number of FOCUS scenarios and a series of national scenarios. Knowing the representativeness and in particular the protectiveness of these scenarios is key to building confidence in the risk assessments being made, both at the national and zonal levels. Furthermore, insight into the representativeness and the protectiveness of these scenarios may assist in harmonising the zonal procedure of the risk assessment for pesticide leaching to groundwater. To assess the representativeness of the Northern groundwater scenarios an analysis of the soil and climatic characteristics of these scenarios was conducted. These characteristics were compared with the characteristics of the detailed Footways agro-pedo-climatic combinations covering the Northern zone countries. The analysis focused on climate and soil aspects and was conducted both at the national and zonal levels. Overall, the representativity of the FOCUS/national scenarios with respect to soil and climate for the agricultural area of the Northern Zone countries is low. However, what is important for the risk assessment is protectiveness (i.e. the cumulative worst-case-ness) and not representativeness. To assess the protectiveness of the Northern groundwater scenarios twelve example applications, comprising 12 active substances (both hypothetical and real ones) and 6 metabolites, were defined. The applications were simulated according to the national requirements in the countries in the zone with the PEARL, PELMO and MACRO model. Results obtained for the FOCUS/national scenario modelling were compiled in a table containing overall and annual pesticide leaching concentrations and leaching fluxes for 450 unique combinations of simulated compound, scenario, model and output depth (162 combinations for MACRO, 144 for PEARL and 144 for PELMO). These results were plotted over the spatial cumulative distribution functions (CDFs) of the various leaching endpoints to determine the cumulative worst-case-ness, i.e. protectiveness, of the FOCUS/national scenarios for the individual countries and the whole Northern Zone. The positions of the FOCUS/national scenarios on the national and zonal CDFs of the various leaching endpoints, notably the 80<sup>th</sup> percentile annual PEC<sub>gw</sub>, for the 18 simulated compounds will be presented.

### Surface water risk assessment of pesticides in Ethiopia

B. Teklu, Wageningen University / Environmental Sciences Aquatic Ecology and Water Quality Management Group; P.I. Adriaanse, Alterra Wageningen University and Research Centre / ERA team; M. ter Horst, Alterra, WUR; J.W. Deneer, Alterra Wageningen University and Research Centre / ERA team; P.J. van den Brink, Alterra and Wageningen University

Scenarios for future use in the pesticide registration procedure in Ethiopia have been devised for 3 separate Ethiopian locations, which are considered to be

protective for 99% of Ethiopia. The scenarios estimate concentrations in surface water resulting from agricultural use of pesticides for a small stream and for 2 types of small ponds. Preliminary results from scenario calculations will be presented. On the basis of volume of use, application rate in Ethiopia and acute and chronic human toxicity the 7 pesticides considered to be of most risk to humans were selected, assuming exposure as a result of the consumption of surface water. Estimates of exposure concentrations in surface water were established using modelling software also applied in the EU registration procedure (PRZM and TOXSWA). Calculations generated the 99-percentile maximum concentration for use in human risk assessment and the 90-percentile maximum concentration for use in ecotoxicological risk assessment. Input variables included physicochemical properties, and data such as crop calendars, irrigation information, meteorological information and detailed application data which were specifically tailored to the Ethiopian situation. The results indicate that for all the pesticides investigated the acute human risk resulting from the consumption of surface water is low to negligible, whereas agricultural use of atrazine, Chlorothalonil, dimethoate and Endosulfan may result in medium to high risk to aquatic species. Key words: Risk assessment, pesticides, models simulation, aquatic ecosystem, Ethiopia

#### **Proposal of an intermediate approach to consider effects of wash-off in the soil exposure assessment**

G. Reinken, Bayer CropScience AG; P. Sweeney, Syngenta; K. Szegedi, BASF SE, Agrarzentrum Limburgerhof / APDEF; C. Schriever, BASF; D. Yon, Dow Agrosciences; C. Hatzenbeler, DuPont Crop Protection

A recent draft EFSA guidance published on the 10 July 2014 introduces a proposal of crop canopy processes to be employed for the soil exposure assessment. A part of this proposal is to consider effects of wash-off. This change in the assessment introduces a significant change to the status quo and substantially difference from procedures established at other areas. Thus, implementation of wash-off in soil exposure assessment needs to be adequately aligned to other exposure areas. The described EFSA approach is a work-around to tackle the fact that current versions of FOCUS models calculate wash-off differently. However, the work-around is based on wash-off calculated with two different FOCUS model. Also, the approach is limited to PECsoil, covers only a limited number of crops and allows no use of wash-off refinement values. It is well-known that compounds applied to leaf surfaces may be absorbed into leaves, may degrade on leaves and may be resistant to removal from leaf surfaces by rainfall. Neglecting these processes from the assessment increases the conservativeness of the calculations. Therefore, to offer a more realistic alternative, the use of measured refinement values for the wash-off fraction should be included into the assessment procedure as it reflects compound behaviour; this is already part of FOCUS guidance and accepted by EFSA. ECPA proposes an alternative approach to consider effects of wash-off independent of FOCUS model calculations. Soil loadings resulting from wash-off are calculated based upon rainfall amounts and return frequencies of rainfall that have been conservatively derived from weather data in FOCUS SW and GW met files. Details are described and discussed. This alternative approach leads to very similar values for the "fraction reaching soil" as depicted in the draft EFSA guidance but crucially delivers the following major benefits: measured wash-off refinement values can be easily considered can be consistently employed to all FOCUS crops can be easily implemented in exposure models maintains consistency between exposure estimates calculated by different models established by FOCUS easy support of higher-tier options The presented approach is an interim measure until more is known about the science of wash-off. The FOCUS models may be used directly to estimate wash-off, only after they have been harmonized in view of the wash-off process description and implementation.

#### **Advancements in life cycle impact assessment and footprint method development (I)**

55

##### **How to integrate the spatial dimension in LCA**

L. Patouillard, CIRAIG - École Polytechnique de Montréal; C. Bulle, CIRAIG - ESG - UQAM / Strategy corporate social responsibility; C. Querleu, IFP Energies nouvelles / Economie et Veille; D. Maxime, CIRAIG Polytechnique Montreal; J. Garcia, SCORE LCA; C. Beaudard, Campus LyonTech La Doua

The spatial dimension is an important aspect in life cycle assessment (LCA). Indeed life cycle processes, and so elementary flows (EF), are most likely scattered geographically due to global supply chains. The environmental impacts related to an EF can be different across the globe depending on the spatial variability of ecosystem sensitivity. Integrating spatial dimension seems to be a promising way to increase LCA results' reliability by reducing spatial uncertainties. This work presents a literature review of the existing recommendations and approaches to integrate the spatial dimension in LCA. Then, their relevance and applicability is analysed in order to provide recommendations for its use. This work has been conducted with the support of SCORELCA. Some specific concepts are introduced. *Inventory regionalisation (InR)* deals with increasing the representativeness of process descriptions in order to reflect the variability of the geographical scope. *Impact regionalisation (ImR)* deals with calculating regionalised characterisation factors (CF) that reflect the spatial variability of ecosystem sensitivity. In order to

use those CF, EF should be geographically localised (*inventory spatialisation, IS*). The literature review allows for the identification of 111 recommendations and 36 approaches on the spatial dimension integration in LCA (44 references). They are classified based on their objectives (*InR, IS, ImR*, integration during impact calculation and interpretation phase) and application in LCA databases and software. The literature review reveals that LCA practitioners have used most of the approaches for *InR*. *IS* is a new practice even though the geographic information needed is often easily accessible. The additional workload to integrate spatial dimension depends on the uncertainty level that the practitioner wants to reach. However, some sectors (e.g. the agricultural sector) and impact categories (e.g. land use) require a specific attention for *InR* and *IS*. Ideally, geographical data should be used, but it requires some skills in Geographic Information System tools. An alternative is to use aggregated data or CF enriched with uncertainty related to spatial variability. Practical guidelines are provided in order to help LCA practitioners to deal with spatial variability. This research points out the need for a consistent operational methodology allowing to prioritise the effort of regionalisation in LCA depending on the decision context.

56

#### **Input-output based life cycle assessment of production and consumption in Belgium - Comparison of three Belgian regions based on regionalised input-output data**

V. Zeller, Université Libre de Bruxelles; M. Degrez, ULB / MAT

Most life cycle assessments (LCA) or footprint studies that focus on production and consumption activities are carried out at national level. However, when regional differences in the economic structure occur, the use of more regionalised datasets seems to be more appropriate. Belgium is such a case where regional variation occurs: for example, energy intensity and transport requirements are significantly higher in the Walloon region than in other Belgian regions. The goal of this study is to perform a LCA at the regional level, compare the environmental impacts between regions and sectors and discuss whether such an assessment can improve accuracy of results. Therefore, we develop a multi-regional input-output-model that takes into account interregional and international trade flows. We combine regional supply and use tables from 2003 with data from regional air emission accounts and calculate environmentally extended input-output tables by applying the substitution approach. Based on these tables, we perform the impact assessment for all products (118 product groups) produced and consumed in the Belgian regions. The impact categories are currently limited to air emissions and take into account global warming potential, human toxicity, photochemical oxidation, acidification and eutrophication. The results are aggregated into three product groups (primary production, manufacturing, services) and household consumption. The highest impact intensities occur for household consumption or primary production, followed by manufacturing activities and services. Analysing the variation within a certain product group, a regional variation of up to 85 % can be found for household consumption, 70 % for primary production, 55 % for services and up to 25 % for the manufacturing sector. It depends on the product group which region shows the highest impacts: the Flemish region creates highest impacts in all impact categories of the primary sector, the Walloon region in the manufacturing sector and Brussels in the service sector and household consumption. The results show that for this case study, the regionalisation of input-output data improves accuracy of results. In order to draw safe conclusions the analysis must be conducted for other years and include a detailed product resolution (ongoing research).

57

#### **Conceptual approach and operational tool for consistent calculation of temporally differentiated LCIs**

L. Tiruta-Barna, Université de Toulouse / INSA UPS INP LISBP; Y. Pigne, Normandy University / LITIS; T. Navarrete-Gutierrez, Public Research Centre Henri Tudor; E. Benetto, CRP Henri Tudor / Resource Centre for Environmental Technologies CRTE

Conventional Life Cycle Inventories (LCIs) are static models of product systems, assuming steady state operation of unit processes and neglecting time lags and stocks of products between supply and demand. As a result, the aggregation of environmental interventions without proper consideration of the time dimension can lead to biased Life Cycle Assessment results. We aim to present a novel conceptual and computational framework for the consideration of time dependency in LCIs. Process modelling is used to describe the production flows and environmental interventions of each unit process and supply modelling is used to include time lags and stocks on the raw materials exchanged by unit processes of the product system. The combination of production and supply models in life cycle networks, based on a set of specific temporal parameters (representative functioning period, production time, supply delay, supply frequency), allows the proper characterization of time dependency in each node. For the computation of time dependent LCI, i.e. of the time resolved environmental interventions, a tracking (graph search) algorithm is proposed. To this aim, a Web software was successfully developed. A test bed case illustrating the effectiveness of the conceptual and computational approaches is presented and solved both analytically and numerically. The computational requirements and additional data and information needs for the application of the tool to full scale life-cycle networks are discussed

### Impact assessment meets global sensitivity analysis techniques: misunderstandings, advantages and unexplored potential

S. Cucurachi, Institute of Environmental Sciences(CML) / CML Industrial Ecology; E. Borgonovo, Bocconi University / Management Science Laboratory; R. Heijungs, Leiden University / Faculty of Economics and Business Administration Department of Econometrics and Operations Research

The trustworthiness of LCA as a decision support tool has certainly improved, as its robustness as a field of science. Improvements have especially regarded the impact assessment methods that are used in the LCIA phase. LCIA methods of ever increasing complexity have been developed to deal with a great number of material and immaterial stressors. LCIA methods are now able to capture local differences and provide a spatially-explicit characterisation of emissions, and are also able to consider temporal dynamics. Such improvements have contributed to strengthen LCA. However, the *elephant in the room* still remains the matter of uncertainty. Even though the topic has attracted the attention of developers since the early days of LCA and still comes high in the agenda of meetings and conferences, the methodological proposals to deal with uncertainty analysis have often been neglected in the practice. Together with uncertainty analysis, other statistical techniques have failed to attract the attention of LCA experts. Techniques of global sensitivity analysis are a remarkable example of this trend. Although the literature on the subject is vast and rich of causes for reflection, the literature shows that until now that the LCA world has almost singlehandedly ignored the newest developments in the field. The sheer definition of *sensitivity analysis* appears to be often unclear to LCA practitioners, with the concept often mixed up with uncertainty analysis, or used as a synonym of scenario evaluation. Trying to clarify all misinterpretations and inconsistencies, in this contribution we define a stepwise protocol that uses uncertainty analysis in combination with an ensemble of global sensitivity analysis techniques to fully analyse LCIA models.

### 59

#### The social footprint - A practical approach to comprehensive and consistent social LCA

B.P. Weidema, Aalborg University / Danish Centre for Environmental Assessment  
The term "social" is here understood as it is used in welfare economics, to signify an accounting that encompasses the entire societal economy, as in "social costs", combining private costs and externalities. The "social footprint" is thus to be understood as the result of a complete "life cycle sustainability assessment" (LCSA). The practicality of social footprinting is currently hampered by a lack of focus on materiality of the impacts, an excessive data requirement, and a lack of understanding of the main impact pathways (cause-effect relationships) for social and economic impacts. To overcome these barriers, a practical approach to accounting and assessment is proposed, without loss of comprehensiveness. The approach encompasses: A top-down approach to importance of impact categories (focusing on the relatively few non-overlapping impacts that dominate in global importance as assessed by estimating and monetarising their global impact, rather than spending time and efforts on obtaining data for a large number of overlapping and largely irrelevant indicators) and of inventory data (focussing on processes with high value added or high number of work-hours); A streamlined impact assessment that limits the inventory data requirement and the need for detailed impact pathway descriptions, by focusing on the macro-scale impacts. In contrast to most biophysical impacts, many social and economic impacts are purely location specific (they occur to varying degree in different locations and are unrelated to company-specific actions and choice of technology). The different measurement methods and metrics for these impacts are described, as well as impacts of remediating actions and impacts that depend on company-specific actions and choice of technology. It is argued that locating an enterprise in an area with bad governance has both negative and positive impacts, but the action potential is by far the largest in countries with bad governance.

### 60

#### The water footprint of consumption - tracking origins and impacts through multi-regional input output analysis (MRIO)

S. Pfister, ETH Zurich; S. Lutter, Vienna University of Economics and Business; M.M. Mekonnen, University of Twente

Global agriculture is the main driver of water consumption and related environmental impacts and its products are part of a highly globalized market. Thus, we used the enhanced EXIOPOL multi-regional input output (MRIO) dataset created in the CREEA project. It is accounting for water consumption and trade of 43 countries (representing ~95% of the global GDP) and 5 rest-of-the-world (RoW) regions with a total of 169 industrial sectors and 200 product groups in each country/region facilitating a proper water footprint assessment of final consumption. Since water consumption calculations have high uncertainties we coupled the two main global datasets with the CREEA data for evaluating robustness of the water footprint results. By creating a disaggregation matrix that allows allocating the consumption of a crop group in each region to >10'000 watersheds as a function of the production pattern, water consumption can be characterized by a water scarcity index (WSI) to calculate scarce water footprint (midpoint impact) for any region. Furthermore "green water" (water consumption of soil moisture; a land use indicator) and "blue water" (irrigation water consumption) footprints can be calculated and complement the set of indicators

reported outside full a LCA and the outcomes are compared. The "blue water" footprint of EU27 final consumption of products is mainly located in Europe, the US, China, India, Pakistan, Brazil, Egypt and Thailand. The scarce water originates mainly from Europe, India, Pakistan, the US, China, and Egypt. For green water Sub-saharan Africa and Latin America have a much higher contribution, indicating high land use impacts caused by EU27 production. Interestingly, the share of green, blue and scarce water consumed within the EU27 for its final consumption is roughly between one quarter to one third of the total. This shows the high dependency of EU states on foreign land and water resources. The main sectors contributing to the water footprint is agricultural production, mainly imported as processed bio-based products through other sectors, incl. processed food and leather. The high uncertainty of water consumption values for crop production is reflected by the high difference in the two datasets, even for global totals (factors ~1.6-1.9). Large discrepancies in EU27 water footprint origins are observed for the African and Asia/Pacific regions, but the overall picture is not differing a lot.

### Bioavailability of organic chemicals: Linking science to risk assessment and regulation

### 61

#### Towards a unified approach for the determination of the bioaccessibility of organic pollutants

C.D. Collins, Reading University / Soil Research Centre; S. Alcega-Garcia, University of Reading; M. Craggs, University of Reading / Department of Geography and Environmental Science; K. Kademoglu, University of Reading / geography and Environmental Sciences; S. Lowe, University of Reading  
Bioaccessibility studies have been widely used as a research tool to determine the potential human exposure to ingested contaminants. More recently they have been practically applied for soil borne toxic elements. This paper reviews the application of bioaccessibility tests across a range of organic pollutants and contaminated matrices. Important factors are reported to be: the physiological relevance of the test, the components in the gut media, the size fraction chosen for the test and whether it contains a sorptive sink. The bioaccessibility is also a function of the composition of the matrix (e.g. organic carbon content of soils) and the physico-chemical characteristics of the chemical under test. Despite the widespread use of these tests, there are a large number of formats used and very few validation studies with animal models. We propose a unified format for a bioaccessibility test for organic pollutants. The robustness of the test should first be confirmed through inter laboratory comparison, then tested *in-vivo*.

### 62

#### Use of bioavailability concepts and passive samplers in "real-world" projects in Norway

G. Cornelissen, NGI; S.E. Hale, Norwegian Geotechnical Institute / Environmental Engineering; E. Eek, NGI / Environmental Technology; G.D. Breedveld, Norwegian Geotechnical Institute / Department of Environmental Engineering; M. Schaanning, Norwegian Institute for Water Research; A.M. Oen, Norwegian Geotechnical Inst. / Dept Environmental Engineering; J. Gunnarsson, Stockholm University / Department of Ecology Environment and Plant Sciences DEEP  
In Norway regulation opened up for the inclusion of bioavailability concepts relatively early (around 2007). This has allowed us to include bioavailability in a number of projects on the border of science, consultancy and regulation. Three projects right from the limelight of public interest will be presented: **At the hydropower plant of Hakavika, Norway**, a series of sand blasting activities have resulted in the contamination of the surrounding soil with PAHs from the pipe coatings. A thorough risk assessment was undertaken in order to assess the most important spreading and transport routes for the PAHs in order to suggest the most appropriate remediation method. The site specific soil-water partitioning coefficients were determined to be 250 to 4800 times higher than those used in the model as default parameters. This means that PAHs in this particular soil were much more strongly bound to the soil than the risk assessment model assumed. The PAHs are therefore much less available to organisms and to leach to the surrounding soil, than estimated from the standard values. This knowledge proved especially useful in the selection of the most suitable remediation. **In the Oslofjord, Norway**, a large-scale clean-up of the whole harbour was carried out during 2008-2012. The clean-up consisted of large-scale removal of contaminated sediments, followed by disposal in an adjacent deep-water disposal site. Continuous monitoring of freely dissolved, bioavailable concentrations aided the authorities in evaluating whether the activities remained within the stipulated "contamination budgets". **In the Grenlandfjords, Southern Norway**, the authorities are trying to find solutions for the worst dioxin contamination of Europe. Innovative methods were deployed to estimate risks, such as benthic flux chambers, passive samplers and compartment fate models. A large-scale remediation trial was set up where activated carbon was added as a thin-layer cap. This reduces available but not total concentrations, so that availability concepts were needed to convince the authorities that this was a valid remediation option. Thin layer capping with activated carbon showed an increasing effectiveness in time, up to 85% reduction in fluxes after 5 years, up to 90% reductions in bioavailability (both chemical via passive samplers and biological via bioaccumulation). Including bioavailability concepts has helped in important and large-scale risk assessment and remediation projects.

### The "biological" component of bioavailability: the usage of ecotoxicological tests

J. Roembke, ECT Oekotoxikologie GmbH

In 2008, the International Organisation for Standardisation (ISO) published a guidance document describing methods for the assessment of bioavailability in soils (ISO 2008). Despite the fact that its content is already more than six years old it is still relevant, especially when it states: "The only direct way of measuring bioavailability for an organism to be protected is the use of that organism and to measure the effect and/or the accumulation" of a given chemical. In this contribution, I will – starting with this statement – give an overview on existing (mostly standardized) ecotoxicological test methods useful for the determination and the assessment of bioavailability in the soil compartment. As examples I will focus on soil invertebrates and, to a lesser degree, on plants, mainly because they are relatively well studied and they can be used both as effect as well as accumulation indicators. Because of the high number of organic chemicals (which may end up in soils), the large differences in soil properties (which may influence the availability of these chemicals) and the taxonomic, physiological and behavioural diversity of soil organisms (which may react quite differently), it is obvious that there is not one / best test method to be recommended: in any case a test battery is needed, consisting of methods which reflect the various combinations between chemicals, soils and organisms, especially the different exposure pathways. Of course, this does not mean that these tests have always to be used – but different standardized methods must be available when assessing the bioavailability of a given organic chemical in soil. In addition, I will briefly discuss whether there are still gaps in test methodology. But more importantly, criteria are needed in order to identify those tests which are most suitable and practical for addressing the bioavailability of chemicals in a regulatory context, preferably as part of existing test strategies. One example of an existing test strategy which has explicitly implemented bioavailability, is the TRIAD approach (currently being standardized by ISO). Possible testing requirements of this approach will be presented and discussed.

### Bioavailability and REACH

B.J. Versoonen, European Chemicals Agency - ECHA / Evaluation; C. Ajao, ECHA-European Chemicals Agency  
REACH, the European Regulation on Registration, Evaluation, Authorisation and Restriction of Chemicals requires so-called 'standard information requirements' to be provided by manufacturers and importers of chemicals in the EU. These include a set of ecotoxicological hazard endpoints, depending on the produced/imported tonnage. These information requirements are then used in a risk assessment, the 'chemical safety assessment'. Under the REACH regulation, worst-case assumptions are often used as in a first tier risk assessment. This is also true for bioavailability where 100% bioavailability is initially assumed. However, bioavailability concepts are often used by registrants to refine risk assessment, e.g. in case risks are calculated in a first tier assessment, or for certain endpoints as (part of) justifications to waive testing that is part of the information requirements under REACH. Although the best known bioavailability concepts have been developed for data rich metals, similar approaches are used for organic chemicals and non-metal inorganic substances. REACH explicitly allows for such substance-specific approaches for bioavailability to be used by registrants to deviate from the standard testing regime if a number of conditions are fulfilled. Apart from the scientific validity of these approaches, they for example need to be well documented and justified in the dossier and the increased or decreased uncertainty related from the approaches needs to be documented. In this presentation examples of approaches that have been used under REACH will be used to 1) illustrate aspects which are of specific importance in a regulatory context, 2) explain possible pitfalls of bioavailability approaches, 3) identify issues which need further scientific developments.

### Classification and modelling of non-extractable residue (NER) formation from pesticides in soil

M. Kästner, Helmholtz centre for environmental research - UFZ / Department of Environmental Biotechnology; K.M. Nowak, RWTH Aachen University / Institute for Environmental Research Biology V; A. Miltner; S. Trapp, Danmark Tekniske Universitet / DTU Environment; A. Schaeffer, RWTH Aachen University / Institute for Environmental Research

This presentation provides a comprehensive overview about the formation of non-extractable residues (NER) from organic pesticides and contaminants in soil and tries classifying the different types. Anthropogenic organic chemicals are deliberately (e.g. pesticides) or unintentionally (e.g. polyaromatic hydrocarbons [PAH], chlorinated solvents, pharmaceuticals) released in major amounts to nearly all compartments of the environment. Soils and sediments as complex matrices provide a wide variety of binding sites and are the major sinks for these compounds. Many of the xenobiotics entering soil undergo turnover processes and can be volatilised, leached to the groundwater, degraded by microorganisms or taken up and enriched by living organisms. Xenobiotic NER may be derived from parent compounds and primary metabolites that are sequestered (sorbed or entrapped)

within the soil organic matter (type I) or can be covalently bound (type II). Both types may pose a considerably environmental risk of potential release. However, NER resulting from elevated biodegradation, which means the conversion of carbon (or nitrogen) from the compounds into microbial biomass molecules during microbial degradation (type III, bioNER), do not pose any risk. Experimental and analytical approaches to clearly distinguish between the types are provided and a model to prospectively estimate their fate in soil is proposed.

### Bioavailability of organic chemicals: How to link science to risk assessment and regulation

J. Ortega-Calvo, Instituto de Recursos Naturales y Agrobiología / Agroquímica y Conservación del Suelo; J. Harmsen, Alterra, Wageningen-UR / CALM; J. Parsons, University of Amsterdam / IBED

Bioavailability of organic chemicals: How to link science to risk assessment and regulation Jose-Julio Ortega-Calvo (IRNAS-CSIC, ES), Joop Harmsen (Alterra/Wageningen UR, NL) and John R. Parsons (University of Amsterdam, NL) After more than 20 years of research, the science on bioavailability of organic chemicals is mature enough to be used by regulators and industry. However, this application is still missing. To facilitate the implementation, a SETAC Europe Special Science Symposium has been organized in October 2014. Key speakers coming from industry, regulation and academia presented their few, which facilitated the discussion in break out groups. The goal was to achieve a clear consensus approach among scientist, regulators and industry on how to think on and how to apply bioavailability. For regulation of chemicals (REACH) a prospective few is necessary, as prescribed in European regulation. Bioavailability can have a role in this, but discussions are more leaded by the non-bioavailable part and especially the part that is non extractable (NER). Should this part be considered as non-toxic or as a chemical time bomb. On national level the retrospective few on bioavailability is more important and can have a role in management of contaminated sites. Science offers chemical and biological methods, that are even partly standardized. Methods are available to measure the available part in the pore water and also the potential available part. Using bioassays the effect of the bioavailable fraction becomes measurable. No methods are available to measure the Non Extractable Residue or bound residues. Important result of the discussion was that communication should have an important role in the implementation. Science is able to explain bioavailability, but does not realize that regulations needs measurable data to enable decision making. It was concluded that communication between science and regulation should focus on the parts that are bioavailable (=measurable) and also on the part that is not bioavailable, which is the total measurable amount minus the available amount. It has to be made clear that with these measurable fractions, risks can be explained and that the non-measurable fraction do not cause any risk. Defining only the bioavailable and the non-bioavailable part for regulation, the still going on scientific discussion on definitions can be limited to the scientific world.

## Ecological Consequences of Exposure to Pharmaceuticals (II)

### Accumulation, Distribution, Metabolism and Elimination (ADME) of fluoxetine in a model passerine bird

T.G. Bean, A. Boxall, University of York / Environment Department; J. Lane, The Food and Environment Research Agency; E. Bergstrom, J. Thomas-Oates, The University of York / Chemistry; K. Arnold, University of York / Environment  
The effects and pharmacology of pharmaceuticals are extensively studied in model mammals prior to use in humans. The read-across hypothesis is based on the idea that a pharmaceutical is designed to interact with a specific drug target, many of which have been evolutionarily conserved in non-target species. There is increasing interest in using human and mammalian data to read across to wildlife species to assess the risks posed by pharmaceutical contamination in the environment. Using the scenario of birds ingesting invertebrates from the trickling filters of wastewater treatment plants which are contaminated with the commonly prescribed antidepressant fluoxetine as a case study, the suitability of the read-across hypothesis for mammalian to avian systems was assessed. Previously we have found an environmentally relevant dose of fluoxetine for starlings has the potential to affect fitness related traits. Following 22 weeks of dosing wild-caught starlings in captivity with fluoxetine contained in spiked invertebrates to mimic environmental uptake, dosing was stopped and birds were euthanized 2, 26, 50 and 74 h after the final dose. Internal concentrations (brain, kidney, liver and muscle) and excretion levels of fluoxetine and metabolites were measured using methods including LC-MS/MS and FT-ICR-MS. The internal concentrations at the different time points were used to determine accumulation, distribution, metabolism and elimination (ADME) for starlings. Accumulation was found to be low with tissue concentrations in the range of 3.1-14.4 and 0.2-25.6 ng/g for fluoxetine and norfluoxetine respectively with concentrations highest in the liver and relatively low in the brain. Elimination half-lives were rapid, typically 3-10 hours. Compared with ADME data for humans and model mammals, our results suggest that avian to rodent but not avian to human read-across provides the best support for the use of read-across in avian pharmaceutical risk assessments. The relatively poor match between human and avian ADME data is suggested to be due to differences

between in both metabolic pathways and basal metabolic rate. It is suggested that the low level of accumulation and rapid elimination of fluoxetine and its active metabolite in starlings means that, in order for the effects observed under experimental conditions to occur in free-living birds, uptake of fluoxetine would have to be high and constant and receptors would have to be more sensitive than in humans.

68

#### Exposure of griffon vultures to fluoroquinolones in NE Spain

R. Mateo, U.C.L.M.-C.S.I.C. / Instituto de Investigación en Recursos Cinegéticos; P. Mateo-Tomás, Instituto de Investigación en Recursos Cinegéticos (IREC) CSIC-UCLM-JCCM; I.S. Sanchez-Barbudo, P.R. Camarero, UCLMCSIC; M.A. Taggart, Environmental Research Institute / Environmental Research Institute Veterinary drugs that are commonly used in livestock production can remain as residues within the carcasses of animals after death. As a result, various scavengers, including vultures, may be exposed to a range of potent/highly bio-active compounds – the implications of which remains very poorly characterised. Across Asia, exposure to diclofenac (a non-steroidal anti-inflammatory drug) via this pathway has caused the near global extinction of at least three species of Old World *Gyps* vulture. This highlights the urgent need for far better ecopharmacovigilance and the requirement for more comprehensive life-cycle assessments for pharmaceutical products currently in use. Despite the observed impact of NSAIDs in Asia on scavengers, surprisingly little monitoring data currently exists regarding the fate of pharmaceuticals in the environment and their potential effects on higher wildlife. European vultures provide an obvious starting point for further work; hence, we present data regarding the exposure of griffon vultures (*Gyps fulvus*) to antibiotics in Aragon, NE Spain. Griffon vultures (n=492) were captured at 19 feeding sites in Aragon (NE Spain) between 2008 and 2011. Blood samples were analysed by LC-ESI/APCI-MS. Fluoroquinolones were detected in 15.2% of the plasma samples. Positive samples were detected in half of the “vulture restaurants”, which indicates that not all feeding sites were taking in carcasses containing fluoroquinolone residues. However, at positive sites the percentage of samples with enrofloxacin/ciprofloxacin was as high as 73.5%. With the exception of one sampling site, enrofloxacin (13%) was more frequently detected than ciprofloxacin (7.4%), which may reflect recent exposure in livestock and vultures as ciprofloxacin is a metabolite of enrofloxacin. The mean ( $\pm$ SE) level of enrofloxacin was  $6.5 \pm 1.0$  ng/ml, for ciprofloxacin was  $6.4 \pm 1.2$  ng/ml and for total fluoroquinolones was  $12.9 \pm 1.7$  ng/ml. However, log-transformed concentrations revealed a higher value for enrofloxacin than ciprofloxacin (geometric means = 2.0 vs. 0.2 ng/ml). Further research will be needed to evaluate whether there are potential adverse effects on vultures of exposure to antibiotics through medicated livestock, but the current data indicate that vultures are regularly being exposed to pharmaceutical residues and this may be of concern in relation to the potential exposure to more toxic compounds such as NSAIDs.

69

#### New Approach to Assess the Effects of Veterinary Medical Products (VMPs) on Dung- and Soil Organisms under Field Conditions: Experiences with Sheep Dung.

B. Förster; A. Coors, ECT Oekotoxikologie GmbH; R. Düring, Justus Liebig University Giessen / Institute of Soil Science and Soil Conservation Research Centre for BioSystems Land Use and Nutrition IFZ; M. Ebke, MESOCOSM GmbH Institut für Gewässerschutz; N. Graf; A. Kulenko, University of Giessen; A. Scheffczyk; M. Wohde, Institute of Soil Science; J. Römbke, ECT Oekotoxikologie GmbH

Veterinary medical products (VMPs) are widely used in today's livestock farming. According to the guidelines published by the Veterinary International Conference on Harmonization (VICH) (2000; 2004), ecotoxicological data are required within the registration process of VMPs. For highly effective parasiticides, the environmental risk assessment includes a comprehensive evaluation of their effects on dung- and soil organisms. If concerns are identified in laboratory tests with dung organisms, a higher-tier field study may be conducted. However, there is no standardized method or guideline available for such a higher-tier test. While some information is available regarding the effects of VMPs in cattle dung, almost nothing is known about the risks of VMPs in sheep dung under field conditions. Dung from sheep was collected before and at four time points after the sheep had been treated with a parasiticide ivermectin. From the resulting different dung batches we prepared pats of identical shape and weight. These standard dung pats were exposed on a meadow, typical for Central Germany. After 7 days, ten pats per batch were retrieved from the field and placed into special emergence traps to catch all flies and beetles hatching from the dung. In order to assess effects on dung decomposition, five pats were retrieved at four time points after exposing the pats in the field. At the same dates, soil samples were taken underneath the pats in order to detect possible effects of ivermectin on micro arthropods. In addition, the feeding activity of soil invertebrates was assessed by using the bait lamina method. The results can be summarized as follows: The general feasibility and interpretability of the field study could be demonstrated. Dung flies revealed a high sensitivity towards the parasiticide. Dung beetles were less sensitive. No effects were observed on the feeding activity. No effects were observed on soil arthropods. Decomposition of dung, measured as ash-free mass loss over time, was very fast. It seems to be partly affected by the parasiticide. The methodological details and the

results of this field study will be discussed in the light of the applicability of this approach for a higher tier assessment of effects of VMP in sheep dung on soil invertebrates.

70

#### A comparison of aquatic species responses to anticancer drug exposure

G. Harris, C.A. Harris, J.P. Sumpter, Brunel University / Institute for the Environment

Classic anticancer drugs differ from the majority of other classes of pharmaceuticals in that they are specifically designed to damage cells. Several of these drugs have been measured in the environment, albeit at extremely low concentrations. However, relatively little research has been conducted on their impact on aquatic species. The purpose of this study was to assess whether aquatic species are adversely affected by cytotoxic drugs, and if so, at what concentrations. Six compounds were selected for the study: 5-Fluorouracil (5FU), Cyclophosphamide (CYP), Cisplatin (CIS), Carboplatin (CAR), Hydroxyurea (HYD) and Imatinib (IMB). A microalgae (*R. subcapitata*), an invertebrate (*D. magna*) and a vertebrate (*D. rerio*) were chosen as representative species from different phyla and were exposed to the anticancer drugs following the relevant OECD guidelines. Algae and daphnia were exposed to the six drugs, both singly and as two simple mixtures. Zebrafish were exposed to the first three of these drugs, also singly and as a simple mixture. Growth inhibition of the microalgae was observed for all drugs singly (apart from CAR) with EC<sub>50</sub> values ranging from 0.44 mg/l for 5FU to 3790 mg/l for CYP. It was not possible to generate EC<sub>50</sub> values for the mixture. Nevertheless, inhibition was observed at concentrations greater than that elicited by any individual drug but less than their sum. Immobilisation of the daphnia was observed for all drugs singly with EC<sub>50</sub> values ranging from 2.0 mg/l for CIS to 2320 mg/l for CYP. EC<sub>50</sub> calculation was also not possible for the mixtures but in this case immobilisation was observed at twice the sum of the individual drugs. For the zebrafish exposure studies, a pilot study was first conducted in which a decrease in hepatosomatic index in response to 5FU was observed; however this was not repeatable in two further studies. No response was observed in morphological endpoints (weight, hepatosomatic and gonadosomatic index) for any of the other drugs either singly or as a mixture. Molecular analysis assessing zebrafish RNA expression of genes involved in DNA damage response is ongoing and will also be presented.

71

#### Effects of antibiotics on the growth and physiology of green algae, cyanobacteria and diatoms

J. Guo, The University of York; A. Boxall, University of York / Environment Department; K. Selby, The University of York

A wide range of antibiotics have been detected in the aquatic environment worldwide. Algae, as non-target organisms and primary producers in the environment, are very sensitive and vulnerable to antibiotics. Once algae are exposed to antibiotics, ecosystem processes may be potentially disrupted due to their primary producer status in the food chain. The aims and objectives of this study were: 1) to compare the responses diatoms, green algae and cyanobacteria to commonly detected antibiotics (tylosin, lincomycin and trimethoprim) using standard test methods for effects on growth; 2) to explore the effects of antibiotic mixtures on selected algae species and evaluate the predictive capabilities of CA and IA models for estimating mixture effects; 3) to explore the effects of the three antibiotics on the physiology of the four most sensitive species identified in 1), including effects on algal growth, photosynthesis, respiration and photosynthetic pigment synthesis and how antibiotics affect the acclimation of the algae to light. Currently most approaches for assessing risks of pharmaceuticals only use a single green algae species and/or cyanobacteria species. This study demonstrates large differences in sensitivity both across algae groups and within algal groups and these differences seem to be substance specific. This study also proves that algal photosynthesis process can be damaged by antibiotics by reducing light utilisation efficiency (one potential reason). As the photosynthetic process is the primary mode of energy metabolism in algae, we would advocate that detailed physiological studies should be undertaken to reveal the damage mechanism. Key words: algae, antibiotics, ecotoxicology, physiology

72

#### Behavior modifications: bridging the gap between laboratory assays and natural behavior in Ecotoxicological risk-assessment studies

G. Hellstrom, J. Fahlman, Umea University / Department of Ecology and Environmental Science; A. Lagesson, Department of Ecology and Environmental Science; E. Bergman, Karlstad University / Department of Biology; M. Jonsson, Department of Ecology and Environmental Science; J. Fick, Umea University / Department of Chemistry; T. Brodin, Umea University / Department of Ecology and Environmental Science; J. Klaminder, Umea University / Department of Ecology and Environmental Sciences

Numerous aquatic contaminants, including heavy metals, persistent organic pollutants, pesticides, personal care products and pharmaceuticals, have been shown to alter the behavior of organisms in laboratory studies. The ecological ramifications of such behavioural disruption are still unclear, as very few studies have investigated the topic outside a laboratory setting. Yet, understanding how behavioral modifications measured in laboratory relates to behavior in a complex

natural context are crucial for proper risk assessment of aquatic contaminants. In this study, we have for the first time being able to closely match behavioral modifications induced by an aquatic contaminant (*Oxazepam*) measured in laboratory assays to the *in situ* behavior of a wild Eurasian perch (*Percha fluviatilis*) in their natural environment. By using micro-scale acoustic telemetry we were able to track the behavior of fish over an entire lake with very high temporal and spatial resolution. Eurasian perch exposed to the anxiolytic drug *Oxazepam* were compared to unexposed fish in ecologically important parameters such as interaction with predators, social behavior, activity patterns, diurnal cycles, personality dynamics, as well as survival. Results are discussed from an ecological and conservation perspective. The presentation will include powerful visuals illustrating the way acoustic telemetry can be used to study behaviorally mediated effects of pharmaceuticals and other contaminants in the aquatic environment.

## Fish model species in environmental toxicology (II)

### A new approach to assess sediments toxicity with *Danio rerio* embryos

R. Massei, EffectDirected Analysis; D. Kurth, Helmholtz centre for environmental research - UFZ / Department of EffectDirected Analysis; M. Krauss, T. Schulze, Helmholtz centre for environmental research - UFZ / EffectDirected Analysis; S. Scholz, Helmholtz Centre for Environmental Research / Department of Bioanalytical Ecotoxicology; W. Brack, Helmholtz Centre for Environmental Research UFZ / Effect Directed Analysis

Sediments are a well-known sink for hydrophobic persistent organic pollutants such as PAHs, PCBs or brominated flame retardants. However, recent studies showed that more polar compounds may predominate sediment toxicity if partitioning behaviour is considered. So far toxicity testing of sediments has been conducted with two major approaches: whole sediments testing and testing of extracts after solvent exchange to DMSO or methanol. In biotests with embryos of *Danio rerio* the former suffers from confounding factors such as oxygen depletion, while the latter results in overestimation of the effect of hydrophobic chemicals. In this study we suggest passive dosing as a procedure to simulate the process of partitioning between sediment organic matter, water and biota and to provide a constant and realistic exposure. Testing with *Danio rerio* embryos involved multiple toxicological endpoints such as spontaneous movements, edema, hatching, lethality, AChE activity and locomotor response. The test was conducted for 96 hours using silicone O-rings loaded with extracts of native sediments at concentrations that resemble those in sediment organic matter. Exposed embryos exhibited a concentration-dependent decrease of spontaneous movement and a development of edema. An AChE inhibition of 46.5% was detected after 48 hours and locomotor activity at 96 hours shows a complete absence of swimming and movements at the highest concentrations. Results confirm the suitability of the O-rings with the *Danio rerio* embryo test and the opportunity to use passive dosing in order to conduct bio testing of sediments extract. New toxicity end points could be also added in order to increase the screening power of the bio assay.

74

### Effects of hypoxia on the toxicity of copper in two model fish species, *Danio rerio* and *Gasterosteus aculeatus* L.

J. Fitzgerald, University of Exeter; R. Wilson, Exeter University; I. Katsiadaki, Cefas / Environment and Animal Health; E.M. Santos, University of Exeter / Biosciences College of Life and Environmental Sciences

Hypoxia is a global and increasingly important stressor in aquatic ecosystems, with major impacts on biodiversity worldwide. Hypoxic waters are often contaminated with chemicals but, despite this, little is known about the interactions between hypoxia and chemical stressors. Previous studies have demonstrated some remarkable alterations in the toxicity of some compounds when exposures occur under hypoxia. However, current knowledge spans only a few chemicals and species, and has incompletely investigated the life cycle of aquatic organisms, highlighting a major knowledge gap for evaluating the environmental impact of chemicals, where exposure often occurs under reduced oxygen. It is critical to investigate the interactions between these stressors in order to more effectively and objectively determine realistic safety thresholds for contaminants in aquatic ecosystems. Here, we started to address this issue by investigating if hypoxia affects the toxicological response to copper in zebrafish (*Danio rerio*) and three-spined stickleback (*Gasterosteus aculeatus* L.). Zebrafish and stickleback embryos were exposed to copper under hypoxia (44.7% air saturation for zebrafish or 50% air saturation for stickleback) or normoxia (98.3% air saturation), continuously, from fertilisation to free swimming larvae, or during specific, 24 hour, developmental windows. For zebrafish, copper toxicity is significantly reduced (> 2 fold) under hypoxic conditions when exposures occur continuously throughout development. However, when exposures occurred during specific developmental windows, copper toxicity was suppressed by hypoxia during the first 24h of exposure, was unaffected during the subsequent 24h and was increased in hatched larvae. In stickleback a similar trend was observed. Further work was carried out to investigate interactions between hypoxia and copper toxicity in adult male stickleback, and to document the potential molecular mechanisms responsible for the effects seen, and data is currently being analysed. Our results to date provide strong evidence for the interacting effects of hypoxia and pollutants during embryo

development and are of vital importance for the protection of environmental health in a globally changing climate.

75

### The 3-spined stickleback as a model for endocrine disruption and mixtures toxicology

I. Katsiadaki, Cefas / Environment and Animal Health; P. Antczak, University of Liverpool / Institute of Integrative Biology; T. Williams, University of Birmingham / School of Biosciences; M. Sebire, Cefas; M. Sanders, Cefas / Environment and Animal Health; J. Elphinstone Davis, Cefas Weymouth / Environment and Animal Health; R. Van Aerle, University of Exeter / Biosciences College of Life and Environmental Sciences; J. Chipman, The University of Birmingham / School of Biosciences; F. Falciani, University of Liverpool; A.P. Scott, Cefas Weymouth / Environment and Animal Health

The three-spined stickleback has a number of advantages as a model species which are particularly useful in the fields of endocrine disrupting chemical (EDC) research and regulation. These advantages include unique natural traits which are under hormonal control, such as the androgen biomarker protein spiggin (Katsiadaki et al, 2002), an elaborate reproductive behaviour, strong sexual selection and a sex determination system that is not influenced by environmental factors, other than EDCs. Over the past 15 years an impressive EDC-specific toolbox has been developed for this species. Techniques developed include *in vitro* fertilisation, DNA sex marker, ELISA's for vitellogenin and spiggin, methods for global gene and metabolite expression whilst international test guidelines and guidance documents include the stickleback variant of TG230, TG234 and the androgenised female stickleback screen. Here we review the advantages of the three-spined stickleback from a comparative genomics and endocrinology perspective and provide an update on the stickleback EDC toolbox. The aim is to summarise the insights we have gained into the effects and mechanisms of action of EDCs and chemical mixtures, both in laboratory and field studies. We focus on specific examples of EDC mixture studies where we observed antagonism, synergism and additive responses after exposures to chemical mixtures. Our data suggest that systems biology approaches ('omics' methodologies and computational modelling) provide an excellent platform for the assessment of chemical mixtures toxicity.

76

### Using genomics to understand the mechanisms of chemical toxicity in fish model systems

E.M. Santos, T. Uren Webster, University of Exeter / Biosciences College of Life and Environmental Sciences; L. Laing, University of Exeter / Biosciences; J. Viana, J. Mill, University of Exeter / Exeter Medical School

In recent years, the use of high throughput sequencing has facilitated the study of chemical impacts in target species of concern, without the need to limit mechanistic studies to surrogate model species for which gene sequence information is available. However, for assessing chemical impacts in some physiological processes, including reproduction and development, well-established laboratory models with short life cycles offer significant advantages allowing for the assessment of the rapid impacts of chemical stressors on parameters directly relevant to population level effects. In this context, we have employed both a laboratory model fish species (zebrafish; *Danio rerio*) as well as a native species to UK freshwaters (brown trout; *Salmo trutta*) to understand the mechanisms of chemical toxicity using a combination of genomics, physiological, biochemical and histological measurements. We studied a range of pollutants originating from farming activities in the brown trout, including 17 $\beta$ -oestradiol and commonly used herbicides (linuron, glyphosate and one of its commercial formulations) using RNA-Seq. In order to determine the reproductive consequences of exposure to glyphosate and its commercial formulation, we used the zebrafish as a surrogate species. Our data documented conserved pathways of effect for oestradiol, and distinct from those induced by linuron, a chemical reported to act via anti-androgenic pathways. For linuron, we found a strong down-regulation of the cholesterol biosynthesis pathway, together with a decrease in the concentration of liver cholesterol. Glyphosate and its commercial formulation both induced extensive gene expression changes associated with response to oxidative stress, including at environmentally relevant concentrations. However, reproduction was affected only at the highest concentrations tested, unlikely to occur in the natural environment. We have also investigated the effects of bisphenol A, a commonly used plasticiser, on reproduction in zebrafish, and documented a decrease in fertilisation success. To understand the mechanisms of toxicity of this chemical, we measured the expression of transcripts involved in oestrogen signalling and DNA methylation. Initial results indicate that exposure to bisphenol A results in a down-regulation of transcripts involved in DNA methylation in liver cells, together with alteration in oestrogen signalling pathways.

### Modelling solvent and passive dosing in early live stages fish toxicity tests

F. Smedes, DELTARES / BGS; D. Giesen, VU University / BGS

The fish embryo toxicity test is presently widely used as alternative for testing with live animals because it is compatible with most current animal welfare legislation (1). To estimate the toxicity of substances direct or extracted from environmental samples embryos and or larvae organisms are exposed to aqueous solutions of such

substance at different concentrations for a certain period of time. Adverse effects, deformation, reduced reproduction or mortality are related to concentrations to identify at what concentration an effect will start to occur or e.g. occurs for 50% of the test organisms. However effects are of course not caused by that dosed concentration in the aqueous phase but by the internal concentration in the organism. In equilibrium this internal concentration is related to the concentration in the aqueous phase through the organism water partition coefficient, or if it concerns a neutral hydrophobic substance, the lipid based concentration through the lipid water partition coefficient. In nature embryos result from already contaminated fish but the laboratory cultivated used in toxicity test will have to achieve that equilibrium concentration during exposure in the limited time the test takes. At the same time the uptake should not affect the nominal concentration. With the early live stages fish toxicity tests as an example the presentation will evaluate exposure in toxicity testing as seen through the eyes of a chemist using a simple distribution model and a kinetic exchange model as applied for passive sampling. Consequently also the possible role of passive dosing will be discussed.

## Systems Biology: increasing the capacity, understanding ecosystems and response mechanisms to model chemicals (including nanomaterials) (Systems biology)

### The use of High-Throughput screening technologies in *Daphnia magna* to identify environmental hazards of contaminants

B. Campos, IDAEA-CSIC / Environmental Toxicology; J. Colbourne, University of Birmingham; D. Gilbert, Indiana University / Biology; D. Fletcher, Agilent Technologies; R. Tauler, IDAEA-CSIC; B. Pina, IDAEA-CSIC / Environmental Chemistry; C. Barata, CSIC / Environmental Chemistry  
Recently, we are observing several changes in regulatory paradigms. Nowadays, the main interest of risk assessment is the full characterization of risk across different biological organizational levels on a systems biology like approach. The development of Adverse Outcome Pathway concept in ecotoxicological research provides a stepping stone for the use of alternative testing methods for hazard assessment, allowing to related molecular signatures of initiating events with apical effects of regulatory relevance. With the recent development of high-throughput sequencing technologies and “Omics” derived assays these objectives are now within our reach. We present the development and validation of a new, more complete and public microarray of *Daphnia magna* and its comparison with results from RNAseq. We will present a pipeline for data analysis and interpretation, which will be useful in the description of molecular initiating events, and a chemometric tool data analysis to identify de-regulated genes and link them with apical and regulatory relevant effects. For the development of the gene models, 7 billion mRNA reads (the most information intensive effort until this moment) were used in the frame of the EVIGENE project. These gene models were then used as template in eARRAY platform. Validation was performed using 6 developmental stages of females, 1 adult males and 3 contaminant exposed animals. RNAseq experiments were also performed with the same samples to compare both platforms. The gene models generated are of high quality, with 98% of the reads recovered in transcripts, and all gene loci (99%) were uniquely mapped. Biological function was inferred by homology searches showing that uniquely shared groups *D. magna*-*D. pulex* are the majority (~12K), with fruitfly and Human genes being equally informative (~6K). Advance chemometric tools allowed the recognition of several genes that are key for development and in coping with stress provoked by different environmental relevant contaminants. The microarray validation experimental design showed that for most genes, the multiple probes design behave in similar way, thus allowing us to proceed to a refined design (8 X 60K) without losing information at a much more cost-effective fashion. The development of bioinformatic tools specific for *Daphnia magna* would increase our current knowledge of its molecular regulation and facilitate its adoption as a model organism for regulatory purposes.

79

### Toxicogenomic approach to investigate the effects of Cu and Ag (nano)materials in the terrestrial invertebrate *E. crypticus*: towards the understanding of systems

S.L. Gomes, University of Aveiro / Department of Biology CESAM; C.P. Roca, Universitat Rovira i Virgili / Department of Chemical Engineering; J.J. Scott-Fordsmand, Aarhus University / Department of Bioscience Terrestrial Ecology; M. Amorim, Universidade de Aveiro / Department of Biology and CESAM

High-throughput gene expression tools advance the understanding of mechanisms of toxic-mediated responses. Further, the mechanistic based approach enabled by omic techniques provide information on key events that link changes at lower to higher levels of biological organization. Such data can be integrated e.g. via the Adverse Outcome Pathways (AOPs), towards a systems biology approach. The aim of the present study was to investigate the mechanisms of toxicity for Cu (copper) and Ag (silver) materials using the high-throughput gene expression tool for the soil invertebrate *Enchytraeus crypticus* (Oligochaeta, Enchytraeidae), a 4x44K custom Agilent microarray. Testing was done linked to reproduction effect concentrations

(EC<sub>20</sub>, EC<sub>50</sub>) using 3 and 7 days of exposure. The data analysis was performed following standard R/Bioconductor workflows for one-color mRNA microarrays: quality control, background correction, probe selection, normalization and statistical analysis. Besides the normalization methods provided by Bioconductor, we used a novel normalization procedure (vectorial normalization) in order to improve the detection of small changes of gene expression. Results indicated specific mechanisms of response for the different materials tested. Cu-salt exposure affected mechanisms related with calcium homeostasis and activated the chemosensory system of the enchytraeids. Energetic metabolism was affected differently depending on the copper forms. For Ag, results showed that one of the materials caused a more differentiated transcriptomic profile than the others. Commonly across all Ag forms were the effects on cell cycle control associated with impairment of DNA repair mechanism. The study of gene expression pointed at differences in gene responses to the various Cu and Ag forms tested, information that is notoriously absent in experiments focussing on the standard effect endpoints survival/reproduction. The Adverse Outcome Pathways (AOP) was important to integrate effects from various levels and provide input for risk assessors.

### Comparative genomics in zinc toxicity: a method to bridge current developments

T. De Boer, Vrije Universiteit / Ecological Sciences; R. Vooijs, VU University Amsterdam; J. Legler, VU University / Institute for Environmental Studies; C. van Gestel, VU University Amsterdam / Ecological Science; D. Roelofs, Vrije Universiteit / Inst of Ecological Science

Two of the most promising developments in the field of environmental risk assessment are Adverse Outcome Pathways (AOP) and Species Sensitivity Distributions (SSD). While one development looks at the effects of chemicals on multiple organismal levels of a single organism, the other looks at the sensitivity to a chemical to multiple organisms. Comparative transcriptomics may be a method to combine these two developments. Comparative transcriptomics (also known as comparative genomics) uses high throughput gene expression analysis such as microarray analysis and RNAseq to compare transcriptomic responses between species and is based on the theory that conserved gene sequences (orthologues genes) between species should act in a more similar way to a stressor than non conserved gene sequences. Here we present a study on the comparative transcriptomic responses to zinc exposure in three different ecological and genomic model species: two terrestrial species (*Folsomia candida* and *Enchytraeus crypticus*) and an aquatic species (*Daphnia magna*). All three species were exposed to EC10 and EC50 for 48 and 72 hours after which gene expression was measured. Gene expression analysis for single species revealed that a greater effect for the two terrestrial species (in percentage of genes differentially expressed) than for *Daphnia magna* and the patterns were also different. For *Daphnia magna* EC50 yielded more significant genes at both days then for the EC10 while in both terrestrial species day 2 exposures yielded more significant genes at the EC10 level than at the EC50 level. Ortholog analysis yielded 3268 ortholog groups and 6812 co-ortholog groups. As of now, we only looked at the responses between the two terrestrial species with a comparison for all three species to be completed complete soon. Comparison of gene responses in the ortholog group yielded significant correlations between 303 of the 3268 orthologs. Clustering of these significant orthologs in both species showed that in *Folsomia candida* the orthologs were more co-regulated then for *Enchytraeus crypticus*. Comparative transcriptomics/genomics can be a powerful tool to investigate the similarities and differences in species responses when exposed to comparable stressors

81

### Network-based pathway analysis improves the interpretation of high-throughput data in toxicology studies

C.P. Roca, Universitat Rovira i Virgili / Department of Chemical Engineering; J. Yang, N. Chatterjee, University of Seoul; J. Choi, School of Environmental Engineering Graduate School of Energy and Environmental system Engineering; F. Giralt, Universitat Rovira i Virgili

High-throughput -omics technologies are powerful experimental tools, able to scan with great detail changes of function in cells. However, using this information to identify physiological and organ responses, as required by the framework of Adverse Outcome Pathways, poses a great challenge. Data analysis tools, such as Gene Enrichment Analysis or Pathway Analysis, address this problem using curated collections of biochemical pathways. Most approaches analyze each pathway independently from the rest of pathways, using an over-representation statistic. Hence they yield good results when the biological effect under study corresponds closely to an annotated pathway. Yet, when the experiment triggers effects in a series of interconnected pathways, the interpretation of results becomes much more complex. One reason is that annotated pathways reflect chains of biochemical reactions that have been identified by different studies and in different contexts. The resulting view of the cell is the superposition of all those pathways, without information about how they interact or coordinate to form a single system. We present here a method of pathway analysis which addresses this issue. It is based on a single genome-wide network representation of all the pathways annotated for the target species. We have developed a network statistic that

generalizes in a simple way the current over-representation analysis. The method conceives the cell as a system of interconnected pathways, instead of a collection of independent biochemical circuits. As a result, it can identify pathway crosstalk and complex multi-pathway effects. Besides explaining the underlying principles of the method, we illustrate the benefits in practice with an study of the toxicity of graphene oxide on *C. elegans*. Keywords: pathway analysis, networks, high-throughput, systems biology

82

#### **Integration of Proteomic and Metabolomic Profiling for Studying Zinc Oxide Nanotoxicity in Exposed Lung Tissue Cells**

T. Kristl, C. Ranninger, University of Salzburg / Department of Molecular Biology; M. Rurik, University of Tübingen / Center for Bioinformatics Quantitative Biology; R. Reischl, I. Radauer-Preiml, A. Duschl, University of Salzburg / Department of Molecular Biology; O. Kohlbacher, University of Tübingen / Center for Bioinformatics Quantitative Biology; C. Huber, University of Salzburg  
This study aimed at the screening of cytotoxic effects of zinc oxide nanoparticles to observe the impact on protein and metabolite abundance and to identify affected biochemical pathways. A comprehensive non-targeted proteomics and metabolomics approach was chosen, which captures the influence of external stimuli on a human alveolar basal epithelial cell line (A549). Six different time points were evaluated (0, 1, 3, 6, 12, 24 h) for three biological replicates comparing controls and nanoparticle-treated cells. Proteins were precipitated, while metabolites were extracted from the cell lysates with cold methanol. For proteome analysis, the alkylated and isotope labeled (TMT six-plex) tryptic peptides were separated by capillary ion-pair reversed-phase HPLC in a 150 x 0.2 mm i.d. monolithic column with followed by linear ion trap-Orbitrap mass spectrometry. Separation of the metabolites was performed with reversed-phase or HILIC UHPLC system utilizing a polar endcapped C18 phase (Hypersil Gold aQ C18, 100 x 2.1 mm, 1.9 µm) or a hydrophilic stationary phase (Nucleodur HILIC, 150 x 2.0 mm, 1.8 µm). Detection and identification were based on quadrupole-Orbitrap mass spectrometry. Bioinformatic workflows using the open source software packages OpenMS and KNIME were applied for data evaluation, involving univariate and multivariate statistical approaches to determine differentially expressed proteins and metabolites. In total, 1036 proteins were identified and quantified and 123 of them were up – or down regulated. Upregulation was observable for the following proteins: Heme oxygenase (decycling) 1; Histone-lysine N-methyltransferase 2E; sequestosome 1; complement component 1, q subcomponent binding protein and protein tyrosine phosphatase, receptor type, N (HMOX1; KMT2E; SQSTM1; C1QBP and PTPRN). Twenty-seven molecules are playing a crucial role in the bio function “cellular growth and proliferation”. This function is relevant for colony formation, proliferation and outgrowth of cells. Between 170 and 630 metabolite features were found to be differentially regulated after strict filtering and quality control. The majority of them was down-regulated upon treatment, for example metabolites of the glutathione pathway indicative of oxidative stress. The study clearly shows that both proteomic and metabolomic analysis are valuable tools for studying biological effects of nanoparticles in an epithelial cell model.

#### **Prioritization and management of multiple stressors in river basins: effects of chemical contaminants and natural stressors (II)**

83

#### **Assessment of river water quality in catchments: Impact of urbanization on particle bound pollutant fluxes**

H. Ruegner, University of Tübingen / Water Earth System Science; M. Schwientek, Water and Earth System Science; P. Grathwohl, Uni Tübingen / Center of Applied Geosciences  
Transport of many urban pollutants in rivers is coupled to transport of suspended particles, potentially dominated by storm water overflows and mobilization of legacy contamination of sediments. Concentration of these pollutants depends on the mixture of “polluted” urban and “clean” background particles. In the current study, the total concentration of polycyclic aromatic hydrocarbons (PAHs), the amount of total suspended solids (TSS) and turbidity were measured on a monthly basis in water samples from 5 catchments with contrasting land use in Southwest Germany over up to 1.5 years. In addition, single flood events with large changes in turbidity were sampled at high temporal resolution. Linear correlations of turbidity and TSS were obtained over all catchments investigated and over an extended turbidity range (up to 2000 NTU for the flood samples). Linear correlations were also obtained for the total amount of PAH and suspended sediment concentrations even for very high turbidity or TSS values (> 2000 NTU or mg l<sup>-1</sup>, respectively). From the linear regressions concentrations of PAHs on suspended particles were obtained – and which varied by catchment. The values comprise a robust measure of the average sediment quality in a river network and may be correlated to the degree of urbanization represented by the number of inhabitants per total flux of suspended particles. The findings are promising for other particle-bound contaminant fluxes (PCBs, phosphorus, and several heavy metals, etc.). Recent investigation focus on the type and geochemistry of suspended particles

representing different time periods of pronounced events (total organic carbon and carbonate content, grain size). 1<sup>st</sup> results showed that concentrations of PAHs on suspended particles did not vary much in different grain size fractions.

84

#### **Contribution and remobilization of semi-volatile organic contaminants (SVOCs) from a melting Himalayan glacier**

B.M. Sharma, TERI University / Department of Natural Resources; L. Nizzetto, NIVA; G.K. Bharat, S. Tayal, The Energy and Resources Institute (TERI); L. Melymuk, Masaryk University, Faculty of Science, RECETOX / RECETOX Research Centre for Toxic Compounds in the Environment; O. Sánka, Research Centre for Toxic Compounds in the Environment RECETOX; P. Pribylova, Masaryk University; O. Audy, Research Centre for Toxic Compounds in the Environment RECETOX; T. Larssen, Norwegian Institute for Water Research NIVA

In the past decades, geological environment of the Himalayan mountain glaciers have experiencing the potential impacts of “climate change”, and there are evidences that it may influence the remobilization of semi-volatile organic contaminants (SVOCs) and similar toxic pollutants on a regional scale. In the present study, we have observed the emission of dichlorodiphenyltrichloroethane (DDTs), polychlorinated bipheyls (PCBs), and polycyclic aromatic hydrocarbons (PAHs) in the meltwater of a large Himalayan glacier and have also assessed their relevance on regional scale. A simultaneous sampling of atmospheric meltwater, and bulk-deposition was performed during the months of April – September 2013 along the course of the river Ganges in India, which is a glacier-fed river originating from the Himalayas. We observed a net deposition of DDT and three and four ringed lighter PAHs to the meltwater by gas exchange. In contrast, PCBs volatilize to air, implying glacier meltwater behaving as an important secondary source of PCBs. In the case of four and five ringed heavy PAHs, contribution from glacier was assessed as an offset between their total discharge in the meltwater and bulk atmospheric inputs at two possible nearest control points to glacier snout. The results elucidate that the glacier meltwater is a powerful source of highly toxic four and five ringed heavy PAHs, which were historically accumulated over the glacier from deposition of contaminated atmospheric particles. On a regional scale, the contribution of meltwater associated SVOCs to the total discharge at downstream control points seems significant, thereby indicating glacier as a highly probable secondary source.

85

#### **Risk Assessment of stream water: linking mass discharge from contaminated sites in groundwater with water health**

A.T. Sonne, Danish Technical University / DTU Environment; J.J. Rasmussen, Aarhus University / bioscience; S. Höss, Ecossa; W. Traunsperger, University of Bielefeld; U.S. McKnight, Technical University of Denmark (DTU) / Environmental Engineering; P.L. Bjerg, Technical University of Denmark DTU / Environmental Engineering

Streams are impacted by significant contamination at the catchment scale, in particular as they are often locations of multiple stress, including for example xenobiotic compounds in groundwater originating from contaminated sites, diffuse source pollution (e.g. surface run-off, tile drains) and water abstraction<sup>1</sup>. With the enactment of the European Water Framework Directive (WFD) in 2000 and the corresponding Groundwater Daughter Directive (GDD) in 2006, all Member States are required to ensure the good chemical and ecological status/quality of both groundwater (GW) and surface waters (SW) by 2027<sup>2</sup>. The chemical status in surface water is defined in part by a set of environmental quality standards (EQS) on priority substances (EQS Directive (2008/105/EC) and in part by the individual Member States (e.g. Danish EPA, 2010, BEK nr. 1022). However the relationships between the quality elements used for the classification of ecological status (biological, hydromorphological and physicochemical) is defined in a more holistic manner leaving the Member States free to define the details of their own assessment tools<sup>3</sup>. In this study we evaluate biological methods/tools for risk assessing the impact of xenobiotic contaminated groundwater entering a stream. We focus specifically on the use of invertebrate fauna for quantifying the link between chemical and ecological status. Our results show the presence of both a local and downstream impact resulting from the contaminated groundwater entering Grindsted stream for both the meio- and macrobenthic fauna. This indicates that this type of stressor affecting water bodies are of a significant importance and must therefore be included when conducting risk assessments of contaminated sites. The toxic potential (TU<sub>D.magna</sub>) of the identified xenobiotic contaminants was generally very low suggesting that long term exposure may generate an expected strong effects in the field. The best estimate, for toxicological stress of the ecological status (species richness and diversity) in the stream based on the chemical data, was achieved by calculating TU for all three phases (SW, GW and pore water) from each of the investigated locations in order to assess whether the ecological status was affected.

#### **Contaminants of Emerging Concern in Fish from 4 Spanish Mediterranean Rivers**

Y. Pico, University of Valencia / Medicine Preventive; V. Belenguer, University of Valencia; C. Corcellas, IDAEA / Department of Environmental Chemistry; M.

Díaz-Cruz, IDAEA CSIC; E. Eljarrat, IDAEA-CSIC / Department of Environmental Chemistry; M. Farre, P. Gago-Ferrero, IDAEA CSIC; B. Huerta Buitrago, Catalan Institute for Water Research (ICRA) / Department of Water Quality; A. Navarro-Ortega, IDAEA-CSIC / Environmental Chemistry; M. Petrovic, ICRA; F. Pérez; S. Rodríguez-Mozaz, Institute for Water Research (ICRA) / Water Quality; S. Rodríguez, Catalan Institute for Water Research ICRA; L. Sabater, IDAEA CSIC; G. Santín, IDAEA-CSIC / Environmental Chemistry; D. Barcelo, IQAB-CSIC / Institute for Environmental Assessment and Water Research

Mediterranean Rivers are ecologically vulnerable with prominent losses in biodiversity caused among other factors by pollution. However, the pollution status and effects of emerging contaminants is still largely unknown because the only data nowadays frequently available are the concentrations of particular contaminants in water. The purpose of this study was to provide an accurate spatial analysis of emerging contaminants in fish from the most important Spanish Mediterranean Rivers (Guadalquivir, Ebro, Llobregat and Júcar), so comprehending regional differences in contaminant burdens, and comparing contaminant concentrations to human and wildlife health thresholds to better understand potential effects in these areas. Concentrations of 133 emerging contaminants in 14 fish species were determined. Among ECDs, BPA was at high concentration in wild fish (up to 223.91 ng/g in Llobregat river), whereas TBEP, caffeine and methyl and benzylparaben were the 4 rivers. Diclofenac, citalopram, carbamazepine, velafaxine clopidogrel, carazolol, sotalol and propranolol were the pharmaceuticals detected at concentrations up to 10 ng/g. The most ubiquitous and recurring compound was diclofenac. The UV filters were much more frequent in fish from Guadalquivir river basin (up to 80 % of the samples) than in those from Llobregat (9.1 %), Ebro (18 %) or Júcar (11 %). Pesticides and herbicides were mostly detected on the Júcar River where atrazine deisopropyl, azinphos ethyl, carbofuran, chlorpyrifos, diazinon, dimethoate, ethion, hexythiazox, imazalil, methoalchlor and omethoate were identified. The highest PBDE and PFCs concentrations were in the Llobregat river basin (55.9–520 ng/g lw). There was a good relationship between the presence of these contaminants in water and in sediments, and in fish. However, not all the contaminants detected in water samples were also in fish. A better relationship can be established between compounds detected in fish and in sediments. The levels and concentrations of contaminants, as well as the co-occurrence of different types of them in fishes, are clearly related with the land uses of the area. Contaminant monitoring efforts should continue and management actions can be taken for the protection of aquatic ecosystems. *Acknowledgement* - The authors thank the Spanish Ministry of Economy and Competitiveness for the financial support through the project SCARCE (Consolider-Ingenio 2010 CSD2009-00065).

#### High contribution of legacy pesticides to predicted water and sediment toxicity in agricultural streams

J.J. Rasmussen, Aarhus University / bioscience; P. Wiberg-Larsen, Aarhus University DMU; A. Baattrup-Pedersen, Aarhus University DMU / Department of Bioscience; D. Jacobsen, University of Copenhagen; N. Friberg, NERI (DMU) / Freshwater Ecology

We revealed a history of legacy pesticides in water and sediment samples from 19 small streams across an agricultural landscape. Dominant legacy compounds included organochlorine pesticides, such as DDT and Lindane, and the organophosphate pesticide Chlorpyrifos which has long been banned in EU. Highest concentrations of legacy pesticides were found in streams draining catchments with a large proportion of arable farmland suggesting that they originated from past agricultural applications. These stream samples also revealed the highest concentrations of registered pesticides that are currently in use when compared with samples from less agricultural impacted streams. Concentrations of legacy pesticides alone exceeded the safety thresholds for daphnia in 6 water samples and they increased sum of toxic units (SumTU<sub>D.magna</sub>) significantly in storm water samples from agricultural impacted streams. These streams also exceeded safety thresholds in 50 % of the sediment and suspended sediment samples and the average contribution of legacy pesticides to SumTU<sub>C.riparius</sub> for bed sediments and suspended sediments was > 90%. Our results suggest that legacy pesticides can be highly significant contributors to the contemporary toxic exposure of stream biota, especially macroinvertebrate communities, and that those communities were primarily exposed to legacy pesticides via the sediment.

88

#### Out of sight out of mind: A case study of the long term effect of capping a sea depot of hazardous waste

K.S. Hatlen, Uni Research, SAM-Marin / Environment; M. Haave, Uni Research, SAM-Marin / Uni Research Environment

Kollevågen bay was for 45 years a depot for Bergen citizens, accumulating 450.000m<sup>3</sup> household and industrial waste. The depot was covered with sand and gravel in 1982 and turned into a public beach. It was then re-covered with mesh, sand and gravel in 2005. Kollevågen is now utilized as a recreational area for bathers, boaters and naturalists. Yearly environmental monitoring has been conducted from 2004 till present, comprising sampling of bottom sediment, blue mussel (*Mytilus edulis*), liver and filet of cod (*Gadus morhua*) and filet of turbot (*Scophthalmus maximus*). The samples have been analysed for PCBs (ICES 7) in

sediment and biota, dioxin like (dl) PCBs in filet and liver of cod and PAH-16 and heavy metals in sediment. Because the area is used by people, sand on the beach was sampled for PCBs (ICES 7), and dietary advice for sea food consumption is given each year. Levels of PCBs in bottom sediment increased after 2008 at all stations. In 2012, the sediment at Kolle 1 and Kolle 5 contained 150,4 and 92,8 mg/kg (DW), respectively. Sediment on the beach did however not contain elevated levels of PCBs. The bottom sediment was defined as poor and very poor (Classification by Norwegian Environment Agency) for heavy metals and TBT at Kolle 1, 2 and 5. PCBs in blue mussel had a steady decrease from 2004 (av:10,4 µg/kg) to 2013 (av:3,9 µg/kg). A decrease of PCBs is also seen in filet of cod, while the levels were high in cod liver in 2009 and 2010 and in turbot filet in 2009 and 2012. The levels of dl-PCBs lay above threshold values (WHO-TEF 2005) for cod liver in 2013 (Covered area: 75,20 pg TEQ/g. Outer area: 43,30 pg TEQ/g) and has increased since 2012. The increased concentration of environmental contamination after 2008 seen in many of the parameters, was explained by a ROV survey in 2013. A crevasse in the cover of approx. 100m was detected, rendering contaminants available to the environment. Hence the results have uncovered that attempts to mend a severe pollution problem in a recreational area, was successful for a few years only, and needs a long term solution.

## Metals in the Environment: Fate, Speciation and Bioavailability in Water, Soil and Sediment (II)

#### A comparison between Diffusive Milli-gels and Chelex column assessment copper bioavailability and toxicity to *Ceriodaphnia dubia*

M. Perez, LCABIEIPREM / LCABIE; S.L. Simpson, CSIRO Land and Water / Centre for Environmental Contaminants Research; S. Reynaud, G. Lespes, M. Potin-Gautier, NISTUniversity of Pau; E. Mignard, SOLVAY; P. Chery, Université Bordeaux; J. King, CSIRO Land and Water; C. Jarolimek, M.S. Adams, CSIRO; D. Schaumloeffel, B. Grassl, NISTUniversity of Pau

Environmental risk management requires profound knowledge of the uptake of contaminants by biological systems. Copper is an essential trace element for living organisms but can become toxic above a certain concentration. The strong complexation of copper by a naturally occurring organic ligands, e.g. humic and fulvic acids, lowers the bioavailability of copper and the rate of uptake by organisms. Therefore, the determination of the bioavailability of copper is essential for environmental management. Based on the concept of diffusive gradients in thin films (DGT), but with differing geometry, the Diffusive Milli-gel (DMG) passive sampler was developed for measuring dissolved copper concentrations in natural waters. DMG are composed of a spherical polyacrylamide gel beads in which a cation exchange resin is incorporated: Chelex 100. The manufacturing technique uses a millifluidic procedure that allows precise control of the size and the geometry of DMG beads of around 1 millimeter diameter. The main advantage of this system is to increase the exchange surface and allows a copper diffusion in three dimensions. The DMG technique was applied to assessing the bioavailability of copper in natural waters through comparison with a well-established Chelex-labile column method and bioassays with *Ceriodaphnia dubia*. The study used ten different waters, with a range of dissolved organic carbon (DOC), hardness and alkalinity, that were spiked and equilibrated with copper. The labile copper concentrations measured by the DMG and Chelex-column methods and toxicity response was most strongly influenced by DOC. A strong linear relationship between DOC and the 50% lethality concentration (LC50) for *Ceriodaphnia dubia* was observed ( $r^2 = 0.981$ ). Water hardness and alkalinity did not significantly influence the results. The results indicated that the DMG may provide a similar ability to Chelex-column based approaches to predicting influence of DOC on the bioavailability and toxicity of copper in natural waters. However, the DMG methods can be more easily applied in situ and provide a time-integrated measurement of labile copper, while remaining a good predictor of the toxicity of copper to aquatic organisms.

#### Application of the chronic nickel biotic ligand model in Australia

A. Peters, Wca Environment Ltd.; G. Merrington, Environment Agency; C. Schlegel, NiPERA, Inc.; J.L. Stauber, CSIRO; G.E. Batley, CSIRO Land and Water / Centre for Environmental Contaminants Research; A.J. Harford, Dept. of the Environment / ERISS Environmental Research Institute of the Supervising Scientist Division; R.A. van Dam, ERISS / Australian Government Department of the Environment; J.C. Chapman, Honorary Scientific Fellow - Office of Environment & Heritage / Ecotoxicology; M.S. Warne, DSITIA; C.W. Hickey, National Institute of Water and Atmospheric Research; P.W. Glazebrook, RioTinto Ltd.

The nickel BLMs applied within Europe show some shortcomings in the prediction of nickel toxicity to Australian test species, although to a large extent this is likely to be due to the relatively large apparent differences in the hardness of waters found in Europe and Australia identified by the water chemistry survey. The lower validation limit of the European nickel BLMs is at a calcium concentration of 2 mg l<sup>-1</sup>, and potentially excludes a relatively large proportion of some types of Australian waters from implementation of the existing nickel BLMs. The *D. magna* BLM was able to make reliable predictions of nickel toxicity to the tested

invertebrates (*Ceriodaphnia* and *Hydra*) when the low hardness Magela Creek water was treated as an outlier due to its low water hardness. Poor predictions were made for the toxicity of nickel to fish in Peechelba water, and for the toxicity to *Chlorella* in Tea Tree water. The *C. dubia* BLM provided the most accurate predictions for nickel toxicity to *Lemma*. Modifications to either the fraction of active fulvic acid, or the binding parameters for nickel to fulvic acid, had only a relatively limited effect in improving predictions. Increasing the binding constants of both calcium and magnesium to the biotic ligand provided very good predictions for fish, *Ceriodaphnia*, *Hydra*, and *Chlorella* in all of the tested waters, but did not improve predictions for *Lemma*. This approach does not require any need to distinguish between extremely soft (e.g. Magela Creek < 2 mg l<sup>-1</sup> CaCO<sub>3</sub>) and soft (e.g. Wellington 58 mg l<sup>-1</sup> CaCO<sub>3</sub>) waters when making BLM predictions. It is likely that the apparently different effect of calcium and magnesium which is observed compared to the previously tested North American waters is due to the low concentrations of calcium and magnesium found in some Australian waters. There are indications that soft-water organisms respond differently to hard-water organisms regardless of their origins.

### **Nickel in lotic sediments: Understanding the role of Fe oxides in oxic surface sediments**

D. Costello, Kent State University / Biological Sciences; R. Mendonca, Universidade Federal de Pernambuco / Depto. de Zoologia, Centro de Ciências Biológicas; A. Harrison, University of Michigan / School of Natural Resources Environment; J.M. Daley, University of Michigan / School of Natural Resources and Environment; C.E. Schlekat, NIPERA; E.R. Garman, NIPERA / Ecotoxicologist; C.R. Hammerschmidt, Wright State University / Department of Earth Environmental Sciences; A. Burton, University of Michigan / School of Natural Resources Environment  
The toxicity of Ni in sediments is modified by the availability and cycling of elements that form metal complexes that can limit Ni bioaccessibility. Under anoxic conditions, reduced sulfur (e.g., AVS) and organic carbon (OC) are the primary binding fractions for Ni; however, under oxic conditions, AVS is unstable and OC can be rapidly respired. Fe oxide minerals are stable in oxic sediment and can sorb Ni. Currently, environmental quality standards (EQS) for Ni in sediment recognize that AVS and OC can reduce Ni toxicity, but these EQS may not be appropriate for oxic sediments. We completed a laboratory experiment where two reference sediments with differing binding capacities (i.e., AVS, OC, Fe) were spiked with Ni (reference +4 concentrations) and equilibrated under anoxic conditions. These sediments were aged in a flow-through mesocosm (100 days) while concurrently exposing *Hyalella azteca* to the sediments to measure changes in toxicity during aging. Concurrent sampling of sediment geochemistry revealed dynamics in chemistry and toxicity as surface sediments oxidized. Total Ni pools remained stable but porewater Ni declined, which suggests a change in Ni speciation as sediments aged and oxidized. Further, our toxicity tests showed that sediments became less toxic as they aged. Fe oxides increased through time in surface sediments and sorbed a large fraction of Ni (50-80%). Additionally, a field experiment was completed in four tributaries of the Burntwood River (Thompson, MB, Canada): two tributaries impacted by mine effluent and two reference sites. At each tributary we assessed acute toxicity of overlying water and sediment with *in situ* chambers (*H. azteca* and *Lymnaea stagnalis*), native benthic macroinvertebrate community, overlying water chemistry, and surface and deep sediment chemistry. Effluent tributaries contained elevated sediment Ni (up to ~500 mg/kg) and higher AVS (presumably from sulfate in effluent) than reference sites. Similar to lab studies, we observed Ni sorbed to Fe oxide minerals at effluent sites. *In situ* toxicity assays revealed that neither overlying water nor sediments in the effluent streams were acutely toxic. Sensitive macroinvertebrates (e.g., *Hexagenia*) were observed in reference and effluent tributaries, which suggests that sediment Ni is not causing impairment. Collectively, these studies demonstrate that current sediment Ni EQS are conservative and Fe oxides should be considered in future Ni bioavailability models.

### **The TICKET-UWM model can improve metals/inorganics environmental fate modelling for chemicals management**

F. Verdonck, ARCHE; H. Waeterschoot, Eurometaux; K.J. Rader, Mutch Associates, LLC; K. Oorts, ARCHE; K. Delbeke, European Copper Institute; B.A. Stubblefield, Oregon State University / Environmental and Molecular Toxicology; P. Van Sprang, ARCHE  
EUSES is a multimedia fugacity based fate model used as a decision-support instrument in the European REACH and Biocides Regulations. This model, which enables the user to calculate the risk for man and environment at the local, regional and continental scale, has been developed primarily for organic substances and needs refinements to predict the fate and exposure of metals. The Tableau Input Coupled Kinetic Equilibrium Transport - Unit World Model (TICKET-UWM) was therefore explicitly developed to model transport, fate, and toxicity for metals and considers additionally key processes such as complexation by aqueous inorganic and organic ligands (e.g., DOC), adsorption to particulate organic carbon (POC), binding to biological receptors (biotic ligands), and transport of dissolved metals and solids between the water column and sediment. The aim of this work is to present the conceptual differences between both multi-media fate models for use in

metal risk assessments. Additionally, a comparative model simulation using realistic examples for the metals Cu and Co shows clear differences in exposure concentrations when metal specific features are considered. The TICKET-UWM model allows also for direct risk calculations. As a general conclusion it is therefore strongly advocated to implement metal-specific features in decision-support models such as EUSES in order to increase the ecological relevancy of the risk assessment for metals. The risk characterisation part allows to use a high quality reference database for the several metals included in the model. A comparison between EUSES and TICKET-UWM clearly illustrates that metal-specific aspects significantly affect the outcome of an exposure and risk assessment. It is therefore strongly advocated to further investigate those differences in detail and implement metal-specific features in decision-support models such as EUSES in order to increase the ecological relevancy of the risk assessment for metals.

## 93

### **How do aquatic organisms handle non-essential and potentially toxic metals in their intracellular environment? A comparison among different metals and across different species**

P.G. Campbell, Université du Québec, INRS / INRS Eau Terre Environnement; P. Couture, INRS / Centre Eau Terre Environnement; C. Fortin, University of Quebec / Centre Eau Terre Environnement; L. Hare, INRS-ETE; M. Rosabal, INRS-ETE / Centre Eau Terre Environnement

Over the past 10+ years, we have investigated how aquatic organisms cope when exposed to non essential metals such as silver, cadmium, nickel and lead. These metals can enter living cells in a variety of ways, often by “fooling” the membrane transporters that are responsible for the influx of essential metals. Once inside the cell, the non essential metals may be detoxified, for example by complexation with metallothionein or by sequestration in metal-containing granules. If detoxification is incomplete, these metals will be available to bind to metal-sensitive sites within the cell, such as enzymes or nucleic acids, potentially leading to deleterious effects. To determine whether metal detoxification has been effective or not, we have used a subcellular metal partitioning protocol involving gentle homogenization of the target organ (e.g., gill or liver) or the whole animal, followed by differential centrifugation and heat denaturation steps. The protocol normally yields five or more fractions: cellular debris; metal-rich granules; organelles; heat-denatured cytosolic proteins (HDP); heat-stable cytosolic proteins (HSP). The HSP and granule-like fractions can be considered to represent detoxified metal, whereas the HDP and organelle (e.g., mitochondria) fractions are normally classified as metal-sensitive fractions. This separation scheme is clearly operationally-defined, but it does allow comparisons of the partitioning of different metals in a given species, or of a specific metal across different species. In this communication, we compare the behaviour of Cd and Ni in a unicellular alga (*Chlamydomonas reinhardtii*), an insect larva (*Chaoborus* sp.), a bivalve (*Pyganodon grandis*) and three fish species (*Perca flavescens*; *Anguilla anguilla*; *Anguilla rostrata*). The alga was exposed under controlled conditions in the laboratory, whereas the animals were all collected in the field from contaminated sites representing metal contamination gradients. In all the field-collected animals, we were able to document a metal detoxification response involving the induction of metallothionein-like peptides (MTLP). Less frequently, the non essential metal was sequestered in the granule-like fraction. The results show predictable differences between Cd (a soft metal) and Ni (a harder cation), but for a given metal they also show inter-organ and subtle inter-species differences in the extent of metal detoxification.

## 94

### **Radioisotope techniques and aquatic ecotoxicology: understanding kinetics and organ distribution of metals**

T. Cresswell, ANSTO Institute for Environmental Research; S.L. Simpson, CSIRO Land and Water / Centre for Environmental Contaminants Research; D. Mazumder, Australian Nuclear Science and Technology Organisation / Institute for Environmental Research; P. Callaghan, A. Nguyen, Australian Nuclear Science and Technology Organisation / Life Sciences; M. Corry, Australian Nuclear Science and Technology Organisation / Institute for Environmental Sciences  
Gamma-emitting metal radioisotopes are valuable tools for studying metal bioaccumulation in aquatic invertebrates, allowing the influx and efflux of multiple metals to be analysed rapidly, at multiple intervals during an exposure period, without sacrificing the organism. Furthermore, autoradiography of cryosectioned organisms enables the organ distribution of accumulated metals to be visualised and quantified. In the 1<sup>st</sup> study, *Macrobrachium australiense* (prawns) were exposed to dissolved <sup>109</sup>Cd and <sup>65</sup>Zn either individually or as a mixture of both metals for 3 weeks before being transferred to isotope-free water for 2 weeks to depurate. At the end of the depuration period, prawns were sacrificed, embedded in a resin and snap frozen in liquid N<sub>2</sub> prior to autoradiography. The 2<sup>nd</sup> study exposed one set of 15 prawns to dissolved <sup>109</sup>Cd for up to 2 weeks, with three prawns being removed for autoradiography at set times to determine the location of Cd accumulation in organ tissues. A second set of 30 prawns was exposed to dissolved <sup>109</sup>Cd for either 6 hours (acute exposure) or 7 days (pseudo-chronic exposure) and allowed to depurate for up to 3 weeks. Prawns were removed from the depuration tanks at set times for autoradiography. For the 1<sup>st</sup> study, the majority of Cd uptake was localised within the gills and hepatopancreas, while Zn accumulated in the antennal gland at concentrations orders of magnitude greater than in other organs. This suggested that

*M. australiense* may process Zn much faster than Cd by internally transporting the accumulated Zn to the antennal gland. During the accumulation phase of the 2<sup>nd</sup> study, the gills accumulated Cd at a rate 4 times greater than in the hepatopancreas, with neither organ reaching Cd saturation over the 14 d uptake period. Furthermore, there was an initial delay of 1-2 d before any significant activity appeared in the hepatopancreas. Following an acute exposure to Cd, both the gills and hepatopancreas depurated significant Cd within the first 24 h, while there was no decrease following chronic exposure for the hepatopancreas. This suggests that internal regulation processes are dependent on exposure time. The combination of kinetic studies and autoradiography greatly increases our understanding of how metal transport kinetics and internal processing may influence the toxicity of essential and non-essential metals in the environment.

## Emerging contaminants of urban origin: sources, sampling, analytical issues and remediation techniques (II)

95

### Spatial Variability of Flame Retardants in Indoor Dust

S. Jílková, Masaryk University / RECETOX Research Centre for Toxic Compounds in the Environment; L. Melýmuk, Masaryk University, Faculty of Science, RECETOX / RECETOX Research Centre for Toxic Compounds in the Environment; V. Vojta, Masaryk University / RECETOX Research Centre for Toxic Compounds in the Environment; P. Bohlin Nizzetto, NILU Norwegian Institute for Air Research; M. KrňtkC, J. Klanova, Masaryk University / RECETOX Research Centre for Toxic Compounds in the Environment

Indoor dust is often used to evaluate levels of semivolatile organic compounds indoors, particularly for those with indoor sources, such as flame retardants (FRs). Yet there are uncertainties about the type of information that can be obtained from indoor dust. We conducted detailed sampling to assess spatial variability in indoor dust concentrations and surface loadings, and the relationship between FR sources and dust. From this, we assess the utility of dust for source identification, evaluating overall indoor levels, or human exposure, and identify what practices in dust collection must be used to achieve these ends. In a large residential room 18 individual samples were collected, covering a range of surfaces (carpet, hardwood floor, furniture and electronic surfaces, and windows). Samples were analyzed for 10 PBDEs and 18 novel halogenated flame retardants (NFRs). Concentrations of N<sub>10</sub>PBDEs were 53.8-620 ng/g. Surface loadings were 0.58-278 ng/m<sup>2</sup>. BDE-209 was the dominant compound in dust, comprising 28-97% of IPBDEs. However this distribution had a spatial profile. The contribution of BDE-209 in floor dust was consistently higher than on elevated surfaces (e.g. furniture, tables, windows), with BDE-209 making up 83-97% of IPBDEs on floors, while on surfaces 28-87%. Of the NFRs, 8 were below detection in all samples (TBP-BAE, TBX, TBP-DBPE, TBCO, TBCT and PBBA). Concentrations of INFRs were dominated by BEH-TEBP, syn- and anti-DDC-CO, and 1- and 10-DBE-DBCH. PNFRs were 75.9-884 ng/g, and surface loadings were 0.807-685 ng/m<sup>2</sup>. The spatial distribution of BDE-209 in the room suggested electronics as a primary source of the BDE-209: there was a strong correlation between fraction of BDE-209 in the floor dust and proximity to the TV unit (R<sup>2</sup>=0.92, p<0.001). Similarly, for NFRs, the spatial distribution suggested foam furniture as a source of BEH-TEBP, with a statistically significant relationship between distance from couch and surface fraction of BEH-TEBP (R<sup>2</sup>=0.46, p<0.02). Thus, the spatial distribution of PBDEs and NFRs in a residential environment demonstrates strong spatial variability related to proximity to sources, surface properties, and dust surface loadings. This case study suggests that spatial distributions of FRs in indoor dust can be used as a source identification technique, but more information on the relationship between sources and the spatial distribution of FRs in indoor dust is needed.

96

### Bioaccessibility of flame retardants in household dusts

C.D. Collins, Reading University / Soil Research Centre; S. Alcega-Garcia, University of Reading

Flame retardants (FRs) are frequently added to a wide range of household products e.g. furniture, electrical goods. Many of these products are known to be toxic and significant quantities have been reported in household dusts. There is therefore the potential for humans and particularly children, who are a more sensitive receptor, to become exposed via ingestion. To fine tune risk assessments bioaccessibility measures of these dusts can be undertaken to determine the likely total amount of FRs released in the gastro intestinal tract. Using an established bioaccessibility test for organic pollutants (CEPBET) a range of FRs were studied. The principal control on the release of the FRs from the dust was the log K<sub>OW</sub> of the parent compound. The nutritional status of the test also had a significant effect with higher values recorded when it was operated in the fed state. Using a level 1 fugacity model the results were well predicted suggesting a model approach may be appropriate for a broader suite of compounds.

97

### Air contamination by endocrine disruptors: comparison of active and passive samplers coupled to a multi-residue method

E. Moreau-Guigon, EPHE; F. Alliot, ecole pratique des hautes etudes UMR SISYPHE; M. Teil, C. Bourges, EPHE; A. Desportes, EPHE / UMR METIS; M.

Chevreuil, ecole pratique des hautes etudes UMR SISYPHE  
Over 2 years, spatial (urban/suburban/forest area) and time scale (seasonal/inter-annual) variations of a wide variety of endocrine disruptor compounds (EDCs n= 59) were investigated in ambient air. Associated to a multi-residue analytical method, three different samplers were used: an active sampler and two passive samplers, PUF and leaves of plane trees (*Platanus hybridus*). It was also the first investigation of air contamination at a regional scale in France, which considered EDC distribution in gaseous and particulate phases. All EDCs except tetrabromobisphenol A were encountered in the ambient air at different frequencies up to 100%. Phthalates were the most abundant with concentrations ranging from 10 to 100 ng.m<sup>-3</sup>, followed by polycyclic aromatic hydrocarbons (PAHs) about 1 ng.m<sup>-3</sup>. Polychlorinated biphenyl (PCBs) and bisphenol A concentrations were much lower (around 0.1 ng.m<sup>-3</sup>). In spite of their relatively low vapor pressures, most of EDCs were mainly distributed in the gaseous phase (> 80% in summer) which displayed a high scattering that might explain EDC ubiquity even far away from their emission sources. EDCs were more abundant in summer and rather governed by volatilization, except PAHs which emissions were higher in cold season linked to combustion processes. Benzo(a)pyrene concentrations were correlated to particle matter < 10 µm (PM10) while PCBs and diethylphthalate concentrations were correlated to the temperature. Molecular profiles in PUF samples were similar to those observed in active samples and air concentrations were of the same order. For pollutants trapped inside plane leaves, the first results concern PAHs and show the same profile between PUF and active samples. However, the number of molecules trapped by leaves was higher than by the other samplers, which could be due to the longer exposure time. The quantity of pollutant trapped in leave is also correlated to the air concentration close to the tree. Results for PCBs, PBDEs and phthalates seem to confirm the relationship between leave and air contaminations. It appears that plane leaves are a good indicator of air quality.

98

### Photodegradation of widely used antibiotics - Real world vs laboratory studies. Are algal ponds the way forward?

E. Tzelepi, Lancaster University / Centre for Global EcoInnovation; C.J. Halsall, Lancaster University / Lancaster Environment Centre; K. Waterhouse, Bowland Analytical Support Ltd.

There are a growing number of studies that have detected pharmaceuticals and their active metabolites in a variety of environmental waters including sewage effluent, surface waters, groundwater and even drinking water. However, there are knowledge gaps regarding the fate of these chemicals and how they breakdown under different environmental conditions, perhaps giving rise to recalcitrant degradation by-products. In this study a series of controlled aqueous-based photolytic degradation studies were conducted under a simulated-solar light source for a number of common veterinary antibiotics. Rates of degradation were related to the light dose alongside the qualification of key degradates. These degradation tests were then repeated under natural sunlight in a range of different water types including filtered and unfiltered lake water. Some notable differences were apparent. Interestingly, the presence of microorganisms in the water, particularly certain algal species, appears to be increasing the rates of photochemical degradation for a few of the test chemicals, including degradation of some of the key transformation products. The work here suggests that novel, low-technology methods, based on culturing key aquatic microorganisms, may serve as a plausible route for enhanced removal of dissolved antibiotics and other pharmaceuticals from sunlit waters.

99

### Reactivity of selected pharmaceuticals with ozone and their fate in advanced wastewater treatment

E. Borowska, Silesian University of Technology / Departement of Environmental Biotechnology; M. Bourgin, Eawag Swiss Federal Institute of Aquatic Science and Technology; M. Boehler, Eawag / Department of Process Engineering; H. Siegrist, Eawag / Process Engineering; J. Hollender, Eawag / Environmental Chemistry; C.S. McDell, Eawag / Department of Environmental Chemistry; U. von Gunten, Eawag Swiss federal Institute of Aquatic Science and Technology  
In the recent years the presence of anthropogenic pollutants in the aqueous environment has gained more and more concern. Because of the low removal efficiency of conventional municipal wastewater treatment for many polar contaminants like pharmaceuticals, new treatment methods have been developed. Ozone-based processes have been investigated in laboratory and also pilot- and few full-scale plants. The results showed the huge potential of these methods. The aim of the study was to investigate advanced methods using ozone for wastewater treatment. In the scope of the study was: (i) determination of reactivity of compounds in reaction of O<sub>3</sub>, (ii) identification of ozonation products (OPs) of highly reactive compounds, (iii) investigation of the fate of micropollutants in the ozonation process performed at the full scale ozonation facility in the wastewater treatment plant (WWTP) Neugut in Dübendorf. The Neugut WWTP is the first facility in Switzerland with such a permanent equipment. In the study 8 pharmaceuticals which occur in significant concentrations in WWTP effluents are investigated- 2 antihistamine drugs (cetirizine and fexofenadine), an antipsychotic drug (amisulpride) and 5 hypertension drugs from sartans family (candesartan, losartan, telmisartan, irbesartan, eprosartan). Investigated compounds represent

wide range of reactivity, including very reactive compounds such as cetirizine ( $k_{03}=1.7 \cdot 10^5 \text{ M}^{-1}\text{s}^{-1}$ ), medium reactive compounds such as candesartan ( $k_{03}=563 \text{ M}^{-1}\text{s}^{-1}$ ), but also compounds with very low reactivity such as irbesartan ( $k_{03}=23 \text{ M}^{-1}\text{s}^{-1}$ ). Laboratory studies proved that ozonation leads to formation of transformation products rather than full mineralization. For instance for cetirizine list of 10 OPs was proposed, and 3 of these compounds have a commercial standard. These OPs were included into the monitoring list in Neugut WWTP. Preliminary studies conducted in the full-scale ozonation facility at Neugut WWTP validated the results obtained in the lab-scale. Compounds considered as highly reactive were removed efficiently during ozonation, while the compounds of low reactivity were still detected at lower concentration in the effluent. In parallel to the degradation of parents compounds, the formation of OPs was observed, for instance cetirizine N-oxide was detected while cetirizine was degraded. Detailed studies concerning the fate of organic micropollutants in advanced treatment of wastewater with ozone are in progress.

## 100

### Performance assessment of advanced water treatment processes for the removal of per- and polyfluoroalkyl substances (PFASs)

L. Ahrens, Swedish University of Agricultural Sciences (SLU) / Dept of Aquatic Sciences and Assessment; S. Lundgren, S. Englund, C. Persson, Swedish University of Agricultural Sciences SLU / Department of Aquatic Sciences and Assessment; P. McCleaf, Uppsala Vatten; E. Lavonen, A. Keucken, Swedish University of Agricultural Sciences SLU / Department of Aquatic Sciences and Assessment; P. Ericsson, Norrvatten; S.J. Kohler, Swedish University of Agricultural Science / Department of Aquatic Sciences and Assessment; K. Wiberg, Swedish University of Agricultural Sciences (SLU) / Department of Aquatic Sciences and Assessment

Per- and polyfluoroalkyl substances (PFASs) comprise a diverse group of chemicals that have been widely used as processing additives during fluoropolymer production and as surfactants in consumer applications for over 50 years. PFASs are persistent against typical environmental degradation processes and have been found ubiquitously in water, air, food, wildlife and humans. Recently, several drinking water sources had to be restricted or even shut down because of chemical pollution from PFASs in Stockholm and Uppsala, Sweden. In this study, the removal efficiency of PFASs will be evaluated using lab-scale, pilot-scale, and full-scale water treatment techniques. In addition, the effect of the character of dissolved organic carbon (DOC) on the removal efficiency of PFASs will be evaluated. The results showed the best removal efficiency using nanofiltration (NF) membrane techniques (in average 50%), followed by magnetic ion-exchange resin (MIEX<sup>®</sup>, 33%), iron (III) chloride ( $\text{FeCl}_3$ , 16%), and 20 mg L<sup>-1</sup> powdered activated carbon (PAC, 14%). Different removal efficiencies were found for waters having widely different organic carbon compositions, indicating that the DOC characteristics (e.g. source, relative age and degree of humification, pH and absorbance) have an influence on the removal efficiency of PFASs in water. Overall, the results of this study will improve our understanding of the removal efficiency of advanced water treatment processes for PFASs and the role of DOC. The knowledge will help the stakeholders in drinking water industry to make the right investments in future drinking water processes.

## POPs and Pseudo-POPs: Environmental occurrence and exposure (II)

## 101

### Tracing sources for contamination of per- and polyfluoroalkyl substances in ground and drinking water

L. Ahrens, Swedish University of Agricultural Sciences (SLU) / Dept of Aquatic Sciences and Assessment; S. Bergström, Swedish University of Agricultural Science / Aquatic Sciences and Assessment; K.E. Holmstrom, SWECO; E.J. Ribeli, SLU; K. Wiberg, Swedish University of Agricultural Sciences (SLU) / Department of Aquatic Sciences and Assessment

The quality of tap water in Sweden is considered to be high. Recently, however, several water sources had to be shut down because of pollution of per- and polyfluoroalkyl substances (PFASs). In many cases, contamination from a nearby aqueous fire-fighting foam (AFFF) contaminated site is the obvious source. In other cases, tracing the origin of the PFAS pollution is challenging, especially when multiple sources may be responsible and the distance between the PFAS-contaminated site(s) are far from the contaminated well(s). To dimension the problem, we conducted a nationwide survey of PFASs in Swedish surface and drinking water. Grab samples from 41 rivers and 236 municipal drinking water plants, totally supporting 45% of the Swedish population, were analyzed. We also conducted a local source tracing study, where samples were collected in soil, sediment, groundwater, surface water and drinking water at three fire-fighting training sites in Uppsala, Sweden, and in the nearby area. Target analytes included 25 PFASs: including PFCAs, PFSAs, FOSA, methyl and ethyl FOSAs, methyl and ethyl FOSEs, FOSAA, methyl and ethyl FOSAA, and 6:2 FTSA. Five rivers showed distinctly elevated levels above the median ΣPFASs of 4.2 ng L<sup>-1</sup>. PFOS exceeded the annual average Environmental Quality Standard (EQS) of 0.65 ng L<sup>-1</sup> at 12 of 44 sampling sites. In the drinking water, PFASs were detected in 52 of the samples (22 %). Four of the samples exceeded the action limit recommended by the

Swedish National Food Agency (ΣPFASs 90 ng L<sup>-1</sup>), and one sample exceeded also the health based limit (900 ng L<sup>-1</sup>). High levels of PFASs were detected in the ground water near two of the fire-fighting sites (ΣPFASs 1000-8000 ng L<sup>-1</sup>). The PFAS composition changed significantly from the contaminated soils to the aquifer and also along the geohydrological flow path. A Principal Component Analysis of the fingerprints of PFASs in the groundwater showed that one of the contaminated sites matched the fingerprint of the contaminated drinking water aquifer. PFAS contamination of drinking water is a recently detected problem in Sweden. Contaminated sites must be localized and the sources for the contamination should urgently be traced. Our study shows that monitoring and fingerprint analysis can be used for tracing sources for PFAS contamination in ground and drinking water. A prerequisite for successful fingerprinting analysis is broad screening of PFASs including precursors, high measurement accuracy, and low limits of detection.

## 102

### Environmental occurrence and exposure of 182 POPs and pseudo-POPs in surface water in France

F. Botta, INERIS; H. Budzinski, University of Bordeaux / UMR EPOC Equipe LPTC; F. Lestremay, S. ANDRES, INERIS; F. Alliot, M. Chevreuil, école pratique des hautes études UMR SISYPHE; M. Devier, University of Bordeaux / UMR CNRS EPOCLPTC; P. Labadie, University of Bordeaux / UMR EPOC Equipe LPTC; C. Cren, Institut des Sciences Analytiques UMR TRACES Team; e. vuillet, ISA; D. Amouroux, LCABIE IPREM / UMR CNRS; e. tessier, Université Pau; M. Montperrus, Université de Pau; V. Dulio, INERIS

A screening study of emerging contaminants was carried out in 2012 in surface waters in both metropolitan France and overseas départements (Martinique, Guadeloupe, Reunion, Mayotte and French Guiana) as part of the National Action Plan against pollution of the aquatic environment, which implies the regular updating of the lists of substances to be included in monitoring programmes. Different data were collected, such as the presence/absence of each investigated compound (concentration levels above the limit of quantification), the level of concentration observed in the aquatic environment and the degree of exceedance of predicted no effect concentration thresholds (PNEC - Predicted No-Effect Concentrations). 182 substances were selected (out of which 82 analytes to be measured in the water matrix, 134 in the sediment matrix and 48 in both matrices). The substances monitored in this campaign included a large range of contaminants (PAHs & degradation products, alkyl perfluorinated compounds, plasticisers, pharmaceuticals, pesticides, antioxidants, petrol additives, industrial products and personal care products). A total of about 400 monitoring data were collected for each substance for the water matrix and 150 for the sediment matrix. In conclusion, this screening study allowed the collection of about 50000 datasets for chemical contaminants in continental surface water. It has, however, to be noted that this study was focused on a limited number of substances/sites and it is therefore not intended to display the status of contamination of the aquatic environment by micropollutants in France. Further to this screening campaign 64 substances (44 for water and 47 for sediment) were prioritised (based on frequency of quantification, frequency and degree of PNEC exceedance and hazardous properties with a specific focus on bioaccumulation and persistency) and were selected for inclusion in the national Watch List for future monitoring in French aquatic environments (2015-2021).

## 103

### Occurrence of emerging contaminants in environmental compartments in relation to substance properties - a case study based on Swedish and Nordic screening studies

E. Brorström-Lundén, IVL Swedish Environmental Research Institute; M. Rahmberg, IVL Swedish Environmental Research Institute; J. Munthe, IVL Swedish Environmental Research Institute Ltd

In order to identify and investigate the presence of emerging chemicals in the Swedish environment, screening studies have been carried out for more than 10 years. Screening in this context means that environmental samples from various matrices in different geographical locations, also including remote areas, are analysed for certain selected chemicals. The overall objective of a screening study is to investigate the occurrence and concentration levels of selected chemicals in a variety of environmental media. Additional aims are to identify possible emission sources, highlight important transport pathways and to investigate possible up take in biota and accumulation in the ecosystem and risk for human exposure. How widespread a chemical is in the environment depends on factors such as emission sources, use pattern and on its physicochemical properties, e.g. persistence. Screening is a first step in procedures for risk estimates, prioritization procedures and emission control measures. Here we will give an overview of the occurrence of emerging chemicals in different environmental compartments by sorting and ranging data in relation to substance properties using multivariate methods such as Principal Component Analysis (PCA) to determine if any patterns and/or co-variation exist in the data. In this case study environmental pathways and risks will be identified using this methodology. Examples of chemicals which have been included in screening studies are such as flame retardance, (brominated, phosphorus), plasticizers (phthalates), pharmaceuticals and chemicals included in personal care products (siloxanes, UV-filters). Several of the screened substances mentioned above are frequently present in the Swedish environment and in most of the included matrices.

### Occurrence, distribution and bioaccumulation of persistent priority and emerging contaminants in coastal settings (Bay of Cadiz, SW Spain)

M.G. Pintado-Herrera, University of Cadiz; E. Gonzalez-Mazo, University of Cadiz / Physical Chemistry; P. Lara-Martin, Physical Chemistry  
Since the second half of the 20th Century, synthesis of chemical products has experienced an exponential growth. It is therefore necessary to better assess the environmental behavior, persistence and possible toxicological effects of new synthetic organic compounds. In that sense, the present work focus on better understanding the occurrence and fate in coastal systems of a wide variety of hydrophobic (log Kow > 3-4) personal care products (PCPs), and comparing them with those better known persistent organic pollutants (POPs). Distributions of both POPs and PCPs have been analyzed in several environmental compartments from the highly urbanized Bay of Cadiz (SW Spain). More than 100 priority (PCBs, PAHs, pesticides from several classes) and emerging contaminants (fragrances, UV filters, insect repellents, antimicrobials, and new organophosphate flame retardants) have been measured in surface seawater and sediment samples. Additionally, caged clams (*Ruditapes philippinarum*) were deployed in this area during 2013 to account to assess bioconcentration of selected target compounds. About 60% of the target analytes were detected in aqueous samples (up to 2.4 ng/mL). Those compounds showing the highest concentrations were synthetic fragrances such as OTNE, galaxolide and tonalide, followed by UV filters (mostly homosalate and octocrylene). Regarding priority compounds, the occurrence of PAHs was confirmed in all samples, being predominant (up to 82% of total concentration) over many PCPs and the rest of POPs. Other chemicals such as PCBs, pesticides, antimicrobials (i.e. triclosan) and insect repellents were only detected occasionally, and always accounting for less than 5% of the total concentration. Levels of POPs and PCPs in surface sediments were usually between 2 and 4 orders of magnitude higher than in the dissolved phase, which can be expected due to their low polarity. Their distribution patterns revealed different sources, such as the accumulation of hydrocarbons towards the west side of the bay due to intensive road and marine traffic between cities. However, concentrations of target compounds were also related to texture and organic carbon content of sediments. Regarding biota samples, analysis of whole tissues revealed the occurrence of the same contaminants found in both aqueous and particulate phases, and levels were significantly higher than those previously measured in non-exposed organisms, suggesting the occurrence of bioaccumulation processes.

### 105

#### Persistent organic pollutants in European eels (*A. Anguilla*) and American eels (*A. rostrata*): comparison between the Saint-Lawrence estuary and the Gironde estuary

M. Lauzent, LPTC-EPOC, University of Bordeaux / UMR EPOC LPTC; P. Labadie, University of Bordeaux / UMR EPOC Equipe LPTC; L. Peluhet, Université de Bordeaux / UMR EPOC LPTC; K. Lemenach, University of Bordeaux / UMR CNRS EPOCLPTC; P. Couture, INRS / Centre Eau Terre Environnement; M. Baudrimont, Université Bordeaux I; H. Budzinski, University of Bordeaux / UMR EPOC Equipe LPTC

Since 1980, eels suffer from a sharp decline in their population. Many anthropogenic and natural causes are possible. However, eels by their life history characteristics are particularly vulnerable to persistent organic pollutants such as polybrominated biphenyls ethers (PBDEs), polychlorinated biphenyls (PCBs) and organochlorine pesticides (OCPs). In the present work, we present a comparative study of POP levels in American eels (*Anguilla rostrata*) and European eels (*Anguilla anguilla*). The levels of contamination of PBDEs, PCBs and OCPs were quantified in 208 muscle samples of yellow eels and 85 muscle samples of silver eels collected in the Saint-Lawrence estuary (Québec, Canada) and the Garonne-Gironde river-estuary continuum (France). Yellow eels from the Gironde estuary were significantly more contaminated by PCBs and OCPs than eels from the St. Lawrence estuary. As regards PBDE concentrations, the St. Lawrence estuary appears more impacted by PBDEs for silver eels. We also highlighted the fact that the difference in contamination between yellow and silver eels was mainly due to the significant lipid reserves of silver eels that promote the accumulation of lipophilic contaminants such as PCBs, OCPs and PBDEs.

### 106

#### Pyrethroid bioaccumulation in Mediterranean dolphins

Aznar-Aleman; C. Corcellas, IDAEA / Department of Environmental Chemistry; J. Gimenez, R. de Stephanis, Estaci3n Biol3gica de Do3ana (CSIC) / Department of Conservation Biology; E. Eljarrat, IDAEA-CSIC / Department of Environmental Chemistry; D. Barcelo, IQAB-CSIC / Institute for Environmental Assessment and Water Research

Pyrethroids are organic pollutants with high hydrophobicity used as insecticides. Concern exists about aquatic organisms' exposure to their toxicity. They were believed to be converted to non-toxic metabolites in mammals, but our group has detected them in human breast milk and has proved their bioaccumulation in marine mammals and river fish. The present study investigates the occurrence of pyrethroid compounds in liver samples from striped dolphins (*Stenella coeruleoalba*) and common dolphins (*Delphinus delphis*) from southern Spain, as the first attempt to determine the occurrence and bioaccumulation and distribution of pyrethroids in

marine mammal tissues from the Mediterranean Sea. Samples of dolphin tissue were collected from the Abrolan Sea (south of Spain) between 2003 and 2010, including 37 liver samples from striped dolphin and different tissues—blubber, muscle, liver, brain and kidneys—from 11 common dolphins. The analytical method monitored 10 pyrethroids, including cypermethrin and deltamethrin. For the sample preparation lyophilized sample was spiked with internal standards, extracted by sonication and underwent a clean-up with alumina and C18 SPE cartridges. Extracts were analysed by GC-NCI-MS/MS. Method recoveries for the pyrethroids ranged 53-116 % and method LODs and LOQs were 0.02-0.46 ng/g and 0.08-1.54 ng/g, respectively. Pyrethroids were detected in 87 % of the striped dolphins and 100 % of the common dolphins, with total concentrations of 5.210 ng/g lw and 69-2,036 ng/g lw, respectively. These levels were higher than those reported found in dolphins from Brazil (7.0-68 ng/g lw). Permethrin and tetramethrin were the main contributors to the pyrethroid profiles for all tissues. The samples of striped dolphins were used to observe that bioaccumulation of pyrethroids was unlike that of persistent organic pollutants (POPs), as pyrethroid levels were not correlated to the age of the specimens. Levels slightly increase from calves to juveniles, whereas juveniles present similar levels to adults. Metabolization of pyrethroids after achieving sexual maturity might account for this pattern. Because of the pyrethroids lipophilic behaviour, blubber was the most contaminated tissue and brain showed the lowest levels. Normalizing the data to the lipid content, the highest value was for muscle by far, suggesting a preference for that tissue.

### Aquatic Nanotoxicology: from Freshwater to Seawater - overcoming the difficulties of standard toxicity tests and the implications for higher tier toxicity testing (II)

### 107

#### Effects of titanium dioxide nanoparticles on aquatic ecosystem: The first outdoor mesocosm experiment

B. Jovanovic, Ludwig Maximilians University of Munich / Chair for Fisheries Biology and Fish Diseases

During the course of the 78 days nine outdoor mesocosms, capacity 1350 L each, situated on a pontoon platform in the middle of a lake were exposed to 0  $\mu\text{g L}^{-1}$   $\text{TiO}_2$ ; 25  $\mu\text{g L}^{-1}$   $\text{TiO}_2$ ; or 250  $\mu\text{g L}^{-1}$   $\text{TiO}_2$  nanoparticles five times a week. E171 human food additive grade  $\text{TiO}_2$  was used using environmentally relevant concentrations arriving from wastewater treatment facility plants. Mesocosms were inoculated with sediment, phytoplankton, zooplankton, macroinvertebrates, macrophytes, and fish before exposure simulating a complete food chain. Physicochemical parameters of the water; nutrient concentrations; and the biomass of the various taxons were monitored. Concentrations of 25  $\mu\text{g L}^{-1}$   $\text{TiO}_2$  and 250  $\mu\text{g L}^{-1}$   $\text{TiO}_2$  have caused reduction in the amount of the available soluble reactive phosphorus in the mesocosms by 10 % and 25 % respectively, but not in the amount of total phosphorus. The biomass of Rotifera was significantly reduced by 36 % and 48 % in the  $\text{TiO}_2$  25  $\mu\text{g L}^{-1}$  and  $\text{TiO}_2$  250  $\mu\text{g L}^{-1}$  treatments respectively when compared to the control, however the biomass of other monitored groups: Cladocera, Copepoda, phytoplankton, macrophytes, chironomids, and fish remained unaffected. In conclusion, environmentally relevant concentrations of  $\text{TiO}_2$  nanoparticles may negatively affect certain parameters and taxons of the freshwater aquatic ecosystem. However, these negative effects are not big enough to affect the overall function of the ecosystem as there were no cascade effects that could lead to a change in the trophic state and primary production, or in a major shift in a food web.

### 108

#### Responses of stream microbial communities to nanosilver: search for effective stress indicators

A. Tlili, Eawag / Environmental Toxicology; A. Pradhan, University of Minho / Department of Biology; C. Pascoal, F. Cassio, University of Minho / Centre of Molecular and Environmental Biology (CBMA), Department of Biology; M.O. Gessner, Institute of Freshwater Ecology and Inland Fisheries  
Global increases in the commercial use of nanoAg have raised concerns about the release of nanoAg into fresh waters, causing a potential risk to aquatic biota and associated ecological processes. In streams, microbial communities play a key role in organic matter turnover and energy transfer from plant-litter to higher trophic levels. However, little is known about their responses at the community level to environmentally realistic concentrations of nanoAg. We investigated responses of stream microbial communities to low concentrations of nanoAg by determining i) dose- and time-response curves and ii) effective physiological indicators for oxidative stress induced by nanoAg and ionic Ag. To this end, stream microbial communities involved in leaf-litter decomposition were exposed to citrate-coated nanoAg (~30 nm d.m.; 4 levels  $\leq 50 \mu\text{g L}^{-1}$ ) for 6, 24 and 96 h. Effects of  $\text{Ag}^+$  (2.5  $\mu\text{g L}^{-1}$  as  $\text{AgNO}_3$ , corresponding to 5% of dissolved Ag(I) from the highest concentration of nanoAg used) were compared with those of nanoAg. Exposure to nanoAg decreased fungal species richness and reproduction in a dose- and time-dependent manner, but did not affect fungal biomass. All tested antioxidant enzymes involved in the ascorbate-glutathione cycle showed similar response patterns to nanoAg. Activities of superoxide dismutase (SOD), catalase (CAT),

glutathione peroxidase (GPx) and glutathione S-transferase (GST) increased with increasing nanoAg concentration and exposure time. The stress responses to Ag<sup>+</sup> were stronger than to nanoAg at a 10 times higher concentration, but weakened with time. Higher activities of SOD and GPx indicated greater contributions of these enzymes to antioxidant defence against the stress induced by nanoAg. Overall, these results suggest that the antioxidant enzymes related to the ascorbate-glutathione cycle can play a key role in the antioxidant defence mechanisms of stream microbial communities against the stress induced by nanoAg at environmentally realistic concentrations. The impacts of Ag<sup>+</sup> were more pronounced than those of nanoAg and they decreased with time. This might be related to a decline in silver bioavailability. Acknowledgements: This study was supported by the SNF through its NRP 64 program, the DAAD-FCT-2013-2014, PTDC/AAC-AMB/121650/2010 and PIDDAC-PEst-OE/BIA/UI4050/2014.

## 109

### Pollution induced community tolerance of microbial decomposers to silver nanoparticles

**D. Batista**, University of Minho / Centre of Molecular and Environmental Biology CBMA; A. Tili, Eawag / Environmental Toxicology; M.O. Gessner, Institute of Freshwater Ecology and Inland Fisheries; C. Pascoal, F. Cassio, University of Minho / Centre of Molecular and Environmental Biology (CBMA), Department of Biology

The production and use of silver nanoparticles (AgNPs) has significantly grown over the last decade. This has increased the risk that a fraction of the NPs is transported to wastewaters and ultimately to rivers and coastal waters where NPs and released ionic silver can have toxic effects. Plant litter decomposition is an important ecosystem process promoted by both fungi and bacteria, different species of which may vary in their sensitivities to pollutants. Based on the concept of pollution-induced community tolerance (PICT), the main goal of the present study was to determine whether exposure of bacterial and fungal decomposers to low doses of nano and ionic silver shifts microbial community structure and thus increases community tolerance to nano and ionic silver. Microbial communities associated with leaf litter were exposed for 25 days to AgNPs (50, 100 and 200 µg L<sup>-1</sup>) and AgNO<sub>3</sub> (20 µg L<sup>-1</sup>). Tolerance acquisition was measured in short-term bioassays to establish dose-response curves for several endpoints: fungal sporulation, bacterial production, microbial respiration and the potential activity of leucine aminopeptidase (LAP). AgNPs were stable throughout the experiment. Cluster analysis of DGGE fingerprints showed that fungal and bacterial communities were affected by long-term exposure to AgNP and AgNO<sub>3</sub>. For all pre-exposed communities, the concentration inhibiting sporulation and bacterial production by 50% was higher for nano than for ionic silver. All endpoints analysed support the PICT concept, since communities pre-exposed to AgNP and AgNO<sub>3</sub> were always more tolerant to nano and ionic silver than the control community. These results suggest that the application of PICT to aquatic microbial decomposer communities provides a powerful tool for AgNP risk assessment.

## 110

### The impact of silver nano-particles to planktonic microorganisms: from viruses to pico- and nano- sized protists

**A. Tsiola**, Institute of Oceanography; P. Pitta, Hellenic Centre for Marine Research Crete / Institute of Oceanography; A. Callol, M. Kagiorgi, I. Kalantzi, Hellenic Centre for Marine Research / Institute of Oceanography; M. Tsapakis, Institute of Oceanography

Planktonic microorganisms play a key role in global biogeochemical cycles and regulate the great majority of oceanic processes. The importance of marine microbial life raised the need for accurate enumeration of the abundance and accurate conversion to biomass of the main microbial members. Under the current scenarios of increased concentration of nano-materials flowing into the oceanic realm, the necessity to study marine microbial assemblages is particularly high. For this reason, during this project, we aimed to assess the impact of silver nano-particles (AgNPs) on the living organisms of the planktonic food web of an oligotrophic coastal area, with the use of microcosm and mesocosm experiments. To our knowledge, this is the first time that such experiments have been designed in the marine environment, providing the opportunity to include all major players of an oceanic system and study their responses to AgNPs manipulation. The interplay between viruses and pico- and nano-sized microbes (bacteria and protists) was assessed, in terms of abundance and biomass, with the use of syringe pumped and conventional air pressure flow cytometry on a daily basis. Bottles and mesocosm bags were filled with water from the bay of Gourmes (Heraklion, Crete) and were finally deployed in a large concrete tank, at *in situ* temperature. Three incubations were not manipulated and served as controls, while the rest received a certain amount of AgNPs. Results from the microcosm experiments aided in the final decision of the AgNPs added, in order to mimic as realistically as possible their expected effect in the future; low concentrations of AgNPs showed a dissolution

trend, BPEI coating (in contrast to) hindered dissolution to a greater extent than the controls, while it allowed significantly higher increase of chlorophyll. Assessing the dynamics of the key producers and recyclers of organic material in the oceans in response to elevated AgNPs is of critical importance. Abundance and biomass are crucial parameters when studying complex microbial assemblages that provide invaluable information regarding the interplay among the microbial food web components. In combination with associated measurements, such as bacterial activity assays (live/dead assessment) and oxidative stress response (production of reactive oxygen species), the impact of introducing AgNPs in aquatic ecosystems will be evaluated.

## 111

### Biomarker responses and silver accumulation in fish chronically exposed to silver nanoparticles in a lake ecosystem

**J.D. Martin**, Trent University; V.S. Langlois, Royal Military College of Canada (Dept. of Chemistry) / Chemistry and Chemical Engineering; M.D. Rennie, University of Manitoba; C.D. Metcalfe, Trent University / Water Quality Centre Due to the antibacterial properties of silver nanoparticles, these nanomaterials are found in an increasingly wide range of food packaging materials, textiles, household appliances, cosmetics, and medical devices. There are concerns that silver nanoparticles are entering waterways from municipal sewage systems in low (µg/L) concentrations, and their effects on aquatic ecosystems are poorly understood. The toxicity of silver nanoparticles may be due to the nanoparticle itself, the release of silver ions, or a combination of both. The goal of this research was to determine if silver nanoparticles added to a lake (i.e., Lake 222) at the Experimental Lakes Area, ON, Canada induced biomarker responses and resulted in accumulation of silver in yellow perch (*Perca flavescens*) and northern pike (*Esox lucius*) that are resident fish in the lake. Suspensions of PVP-capped silver nanoparticles were added to the lake continuously over 18 weeks (i.e., June to October, 2014) from an onshore point source. Concentrations of silver in the water column estimated by deploying passive samplers at five sites in the lake indicated that there was gradient of concentrations across the lake, with time weighted average concentrations

## 112

### Impact of Nanoplastic Particles on the Innate Immunity of Fathead Minnow (*Pimephales promelas*)

**A. Greven**, Chair of fish disease and fisheries biology LMU Munich; T.M. Merk, Ludwig Maximilians University of Munich / Chair for Fish Diseases and Fisheries Biology; M. Klapper, Max Planck Institute for Polymer Research / Department of Synthetic Chemistry; B. Jovanovic, Ludwig Maximilians University of Munich / Chair for Fisheries Biology and Fish Diseases; D. Palić, Iowa State University / Biomedical Sciences

Pollution of the oceans with large and small-scale plastic litter is an area of growing concern. Large plastic items are a well-known threat to aquatic wildlife. However, micro and nano-sized plastic particles can easily be ingested by various aquatic organisms and potentially interfere with natural defense mechanisms leading to health problems. Microplastic has shown to cause granulomas and inflammatory reactions in blue mussels but little is currently known about the effect of micro-, and nano-plastic on the immune system of vertebrates. The effect of polystyrene (PS) and polycarbonate (PC) nano-sized (400-800 nm) particles (NP) on the innate immune system of a model fish species, fathead minnow (*Pimephales promelas*), was examined using neutrophil function assays. To determine the effects of PCNP and PSNP on the innate immune response *in vitro* application of NPs on neutrophil oxidative burst, degranulation of primary granules, and neutrophil extracellular trap (NETs) release assays were used. Application of both PSNP and PCNP (0.1 µg µl<sup>-1</sup> each) caused a significant stimulation of oxidative burst, degranulation, and NETs release of up to 30-100% increase compared to a non-treated control. This study outlines the stress response of the innate immune system of fish and indicates a potential for polystyrene and polycarbonate nanoparticles to interfere with disease resistance in fish populations.

## Modelling of pesticides and biocides fate and exposure in a regulatory context (II)

## 113

### VULPES WEB, a user-friendly web software for the evaluation of groundwater vulnerability to pesticides at territorial level

**A. Di Guardo**, Università degli Studi di Milano-Bicocca / Department of Earth and Environmental Sciences; A. Finizio, Università Milano - Bicocca The groundwater Vulnerability to Pesticide software system (VULPES) is a user-friendly, GIS-based and client-server software developed to identify vulnerable areas to pesticides at regional level making use of pesticide fate models. It is a Decision Support System developed as a web application software aimed to assist the public policy makers to investigate areas sensitive to plant protection products in order to propose limitations of use or mitigation measures. VULPES works at NUTS 2 level identifying the so-called Uniform Geographical Unit (UGU) which are areas characterised by the same agro-environmental conditions (soil type, meteorology, irrigation amounts). In each UGU it applies the PELMO or the PEARL model (according to user's choice) obtaining the 80th percentile of the

substance concentration at 1 meter depth; then VULPES creates a vulnerability map in shapefile format which classifies the outputs comparing them with the lower threshold set to the legal limit concentration in groundwater (0.1 µg/l). VULPES allows making ad-hoc modifications to several input data, such as active ingredients physical-chemical properties, crop or soil parameters in order to address user's needs.

#### Kinetics of rapid covalent binding of aromatic amines to soil

M. Matthies, University of Osnabrueck / Institute of Environmental Research; M. Theiling, University of Osnabrueck / Physics; K. Hideg, University of Pécs / Organic and Medicinal Chemistry; H. Steinhoff, University of Osnabrueck / Physics

The spatial and temporal variability of the exposure and fate of pesticides, biocides, and other chemicals in soil and sediment is controlled by their transformation, sorption and binding processes. In biodegradation simulation studies, many of these xenobiotic chemicals exhibit a large fraction of residues, which cannot be further extracted even by harsh methods ("non-extractable residues", NER). The paper presents a new approach of using stable paramagnetic spin probes for investigating the kinetics of covalent binding of xenobiotic functional groups with natural soils. Luvisol soil (silt loam) and Leonardite humic acid (LHA) were incubated with the nitroxide spin label Anilino-NO (2,5,5-Trimethyl-2-(3-aminophenyl)pyrrolidin-1-oxyl), which contains an aromatic amino functionality susceptible to interaction with soil organic matter (SOM). ESR spectra of soil samples were recorded at X-band frequency (9.43 GHz) at room temperature. A broad ESR signal was observed of Anilino-NO incubated in soil or LHA, which indicates strong restriction of the reorientational motion of the spin probe, i.e. immobilization due covalent binding of the aromatic amino group. This signal increased immediately after incubation and was used to determine the kinetics of the covalent bond formation. The maximum is approached after approximately half an hour followed by a slow decrease, which is attributed to the recombination of the unpaired electron of the NO moiety. A kinetic two-box model was used for fitting the measured values and determining the rate constants assuming pseudo-first order. The reaction of the covalent binding is very rapid in soil with a rate constant of  $9.6 \text{ h}^{-1}$ , i.e. a half-life of 0.072 hours = 4.3 minutes. The loss rate constant is two orders of magnitude smaller. Laccase-treated soil shows an increase of the amount of reactive quinones by a factor of 3, which supports the conclusion of a reaction with SOM. Both rate constants are slightly higher for the laccase-treated soil. Paramagnetic spin probing is an effective method for investigating the rapid formation of covalent binding of xenobiotic functional groups to natural soil. For chemicals containing an aromatic amino group a considerable fraction of NER can be explained as bound residues, which is important for the determination of persistence in soil and sediment required for PBT and risk assessment of pesticides, biocides and other chemicals.

115

#### Effect of using harsh or mild extraction methods in laboratory degradation studies with pesticides on their simulated leaching to groundwater

J. Boesten, Alterra / ERA team

Assessment of leaching to groundwater is an important aspect of the risk assessment of pesticides within the EU. It is known for decades that the extractability of pesticide soil residues decreases with time. So a mild extraction method that may give about 100% recovery after 1 d contact time with the soil may give only e.g. 70% recovery after a few months. In this study the effect of using a mild or harsh extraction method on leaching to groundwater was assessed by simulation. It was assumed that the harsh method extracted always 100% and that the mild method extracted only half of the pesticide molecules sorbed at the non-equilibrium sorption sites. This was based on laboratory incubations with two pesticides in a sandy soil. In these studies the soil was extracted three times and the first extraction was assumed to be representative for the mild extraction method and the three extractions were assumed to be representative for the harsh extraction method. It was assumed that the degradation rate and long-term sorption parameters were derived from a hypothetical laboratory study with the topsoil (20°C, field capacity) from the FOCUS groundwater scenario Okehampton. The substance considered was assumed to have a half-life of 20 d, a desorption rate coefficient of the long-term sorption sites ( $k_d$ ) of  $0.01 \text{ d}^{-1}$  and an  $f_{NE}$  (defined as the ratio of the non-equilibrium Freundlich sorption coefficient divided by the equilibrium sorption coefficient) of 1.0. Its equilibrium sorption coefficient corresponded with a  $K_{om}$  of 35 L/kg. The results of this study (calculated with a submodel of PEARL) were considered as the 'truth' based on the harsh extraction system. From these results the decline of the concentration in total soil was derived for the mild extraction system. This decline and that of the concentration in the liquid phase were used to fit the non-equilibrium sorption parameters and the degradation rate for the mild system. This resulted in a half-life of 18 d,  $k_d = 0.086 \text{ d}^{-1}$  and  $f_{NE} = 0.67$ . The leaching of this substance was calculated for the FOCUS Okehampton scenario with an annual application of 1 kg/ha in winter wheat one day before emergence. The FOCUS leaching concentration for the harsh system was 2.5 µg/L and that for the mild system 2.1 µg/L. So the harsh extraction generated a higher leaching concentration but the effect was quite limited in this exploratory case.

116

#### Validation of the Shell and Scenarios Established for Pesticide Eco-risk Assessment in China through Field Monitoring

J. Zhou, Nanjing Institute of Environmental Sciences, MEP

The Pesticide Risk Assessment Exposure Simulation Shell (PRAESS) was developed by Nanjing Institute of Environmental Sciences (NIES) and Waterborne Environmental Inc. (WEI) to evaluate the potential for pesticides to occur in surface and ground water resources in China. The architecture of PRAESS allows seamless executions of three sets of environmental fate and transport models including PRZM-EXAMS, RICEWQ-EXAMS, and PRZM-ADAM operating under the Windows environment. And currently, six exposure scenarios which can represent the environments characteristic of three typical agricultural regions in China have been incorporated into PRAESS. In order to validate the established shell and scenario system, monitoring studies were conducted at the scenario sites during past years. Comparison of the 90th percentile of maximum daily predicted exposure concentrations (PECs) with the maximum measured concentrations of local used pesticides revealed acceptable agreement for rice-surface water scenarios, but for row crop-surface water and ground water scenarios, more field monitoring data are required for adequate validation.

117

#### Conduct of a Groundwater Monitoring Study using Statistically Valid Survey Approaches to Contextualise PECGW Estimates Obtained from Regulatory Models

D. Wallace, Environmental Safety Environmental Fate; P. Sam, Syngenta Ltd / Environmental Safety Environmental Fate; P. Hendley, Phasera Ltd; A. Newcombe, ARCADIS US Inc

Current regulations governing the registration of plant protection products in the European Union (1107/2009) mandate that an assessment for the potential to reach groundwater is made, primarily using models such as PEARL and PELMO. However, monitoring programs allow the opportunity to measure real-world distributions of concentrations in shallow groundwater to help put the modelled estimates into context. An extensive pan-European groundwater monitoring study was initiated in 2012 to investigate and quantify the distribution of concentrations of two metabolites in very shallow groundwater beneath fields with a history of at least 3 years of herbicide use in the previous 5 years. In order to permit the extrapolation of study findings to all settings where the herbicide is used in EU, the study was designed to ensure selected sites would be spatially distributed to reflect a wide range of agronomic and climatic settings and that the site search would be focused in areas with larger amounts of maize agriculture, higher probabilities of the occurrence of shallow groundwater and in areas where the climatic conditions were favourable for higher metabolite leaching if the herbicide were applied. FOCUS groundwater modelling was conducted to examine the potential for the metabolites to leach following application to maize. The FOCUS simulation models FOCUS-PEARL (v 4.4.4) and FOCUS-PELMO (v 5.5.3) were used in the modelling study. This data is compared with the analytical data generated from groundwater samples collected from installed monitoring wells between March 2013 and July 2014. It was found that at 90% of these very vulnerable sites with a prolonged history of herbicide use and very shallow groundwater, the ground water sampled just downstream of the treated plots contained < 7.6 µg/L of metabolite A and in conclusion, careful monitoring studies designed to follow statistically valid survey sampling approaches can provide solid science based data to put model predictions into context. This study shows clearly that current regulatory modeling for polar metabolites produces PECGW estimates that greatly over-estimate real world concentrations.

118

#### Pesticide exposure modelling in drinking water supply catchments: opportunities, challenges and uncertainties

S. Pullan, TSGE Consulting; M. Whelan, University of Leicester / Geography; I.

Holman, Cranfield University / Energy Environment and Agrifood Pesticides continue to challenge Drinking Water Directive compliance in many surface water catchments used for drinking water supplies in Europe, most commonly due to diffuse-source inputs from agriculture. Catchment-scale modelling is a useful tool for assessing non-compliance risks in such catchments, for helping to identify and prioritise catchment-specific monitoring strategies and for helping to target potential catchment management interventions (e.g. restricted pesticide use on high risk soils). Although models are used for pesticide risk assessment in the EU regulatory authorisation process, these models employ standardised field-scale scenarios which do not necessarily reflect the spatial complexity of the agricultural landscape or temporal complexity of the catchment hydrological response. Small-catchment scale modelling has been identified by the FOCUS Landscape and Mitigation group as a possible higher-tier refinement to FOCUS Step 3 modelling. A simple process-based water balance model linked with a pesticide fate and transport model is described in this presentation. The model predicts daily discharge and chemical concentrations at the catchment scale for a given land use distribution and pesticide application pattern. Physical parameters were derived from the UK soil properties database. The model has been calibrated and validated successfully in five UK catchments for nine pesticide active ingredients. The challenges, uncertainties and opportunities of catchment-scale modelling during model development and model application are discussed.

## Advancements in life cycle impact assessment and footprint method development (II)

119

### Occupational exposures to chemical in Life Cycle Assessment

G. Kijko, CIRAG - École Polytechnique de Montréal / Génie Industriel; O. Jolliet, University of Michigan / Environmental Health Sciences School of Public Health; M. Margni, Ecole Polytechnique de Montreal / Mathematical and Industrial engineering

Life Cycle Assessment (LCA) is a comparative method that aims to assess potential environmental impacts of a product life-cycle onto several "protection areas". It helps preventing burden shifts from one area to another while minimizing the global life-cycle. Human Health is one of these areas covered by LCA and notably include potential impacts on Human Health from exposures to chemicals emitted to the outdoor environment by industrial processes and activities along the product life cycle. However, indoor exposure of workers have not yet been included in the LCA framework despite its known contribution to occupational impacts. This research aims to (a) develop a novel methodology linking measured occupational concentrations to potential impacts to workers within the LCA framework, (b) expand this approach to address occupational exposure across the whole product supply chain and (c) apply these methods to a case study identify hotspots in the life-cycle and to compare the occupational exposures to population exposures due to outdoor emissions. This research shows that potential impacts due to occupational exposures to chemicals are not negligible when compared to other well known source of impacts on Human Health. We show that potential impact for the whole industrial sectors during one year is equivalent to the annual impacts from PM 2.5 exposures due to outdoor emissions. We also demonstrate that depending on the industrial sector the main contributor to the occupational exposures may be found along the supply chain rather than the industry itself: the relative contribution of the supply chain to the total potential impact on worker ranges from 10% up to more than 85%. and should therefore be included in the scope of Life Cycle Assessment. This research shows the relevance to include occupational exposure in LCA and provides an operational method allowing practitioners to include it in LCA studies. We provide direct, indirect (supply chain) generic characterization factors for occupational exposures in each industrial sectors. This enables practitioners to integrate occupational exposures to chemical in LCA. The method allows the use of more specific data (concentrations, hours) when it is available.

### Dynamic toxicity modelling based on the USEtox matrix framework

P. Fantke, Technical University of Denmark / Quantitative Sustainability Assessment; O. Jolliet, University of Michigan / Environmental Health Sciences School of Public Health; C. Wannaz, The University of Michigan, Ann Arbor / SPHEHS

While it is recommended to report characterization factors for different time horizons, e.g. for infinity (steady-state) and after 100 years, the UNEP/SETAC toxicity model USEtox 1.01 only allows for steady-state calculations. The present paper addresses this lack of temporal flexibility and aims to a) develop a dynamic multimedia model based on and fully compatible with the USEtox steady-state matrix framework, b) analyze and interpret the main parameters affecting chemical fate and exposure dynamics, and c) evaluate whether for 3000+ USEtox 1.01 chemicals a 100 years time horizon will yield considerably different results than the steady-state default assumption. To solve the dynamics of the system, we apply a classical approach based on Eigenvectors and Eigenvalues that diagonalizes the rate constants matrix. The fate factor matrix after 100 years can then be calculated as a simple matrix equation as a function of Eigenvectors Eigenvalues. Results show that for organic compounds, such as dioxin, masses in all compartments saturate (i.e. reach steady-state) within 100 days, whereas for metals, such as lead, the soil and deep ocean compartments are far from steady-state even after 100 years. The Eigenvectors and Eigenvalues also help interpreting and understanding the kinetics in each compartment. For the 3000+ organic compounds in USEtox 1.01, there is no difference in fate factors or subsequent intake fractions between 100 years and steady-state values. The only difference appears for metals fate in the deep ocean and in soil, with a reduction of both fate factor in soil and related intake of agricultural produce after 100 years to between 7% and 84% of the steady-state values. We conclude that considering a time horizon for metals of 100 years raises the question of the consistency between LCIA results and LCI emissions from metals deposited in landfills, which can span several 1000 years.

121

### Validation of the results from toxicity assessment in LCA using triangulation

S. Roos, Swerea IVF AB / Chemical Engineering; G. Peters, Chalmers tekniska högskola

The European Commission initiative for Product Environmental Footprint is based on life cycle assessment (LCA), with the USEtox consensus model as the recommended impact assessment method for toxicity. The confidence in the scientific robustness will be crucial for the intended users to take actions based on the results. This research work aims to validate the results from toxicity assessment within the context of LCA by benchmarking USEtox with two alternative

approaches in a case study. While strictly speaking there can be no experimental validation of environmental damage predicted in an LCA of a generic product, comparison of the results of three different methods can be considered a form of triangulation in LCA which can potentially provide confidence in an individual method. A textile case was chosen as the textile industry is an intense user of chemicals. Three different quantitative or semi-quantitative methods for toxicity assessment were used: the USEtox model chosen for the European PEF work; the Score System presented in the European Commission's Reference Document on Best Available Techniques for the Textiles Industry; and the Strategy Tool presented by Askham. The results show that the three methods do not give a consistent toxicity assessment of the chemicals in the case study. For USEtox the result also depends on whether the practitioner uses the default method or add more characterization factors. The two semi-quantitative methods give more equal importance to the chemicals while the USEtox scores differ by several orders of magnitude. The Simple Score System and the Strategy Tool are very concerned with persistent pollutants and therefore the chemicals which are not readily biodegradable, receive a high score. The USEtox score on the other hand is relatively low for the persistent organic chemicals. Validation of results using triangulation can be used both to create confidence and/or help identify new challenges that were not previously perceived in the method. In this case we showed that the property of persistence is judged to have lower importance in USEtox compared to the two other methods, which is a finding that can be used to develop the fate modelling in USEtox. On the other hand, USEtox could provide additional advice compared to the two other methods, that one of the substances could be more environmentally problematic than what these semi-quantitative methods signals.

122

### Approach for a Human and Eco Toxicity Indicator for Construction Products and Works (ToxScale)

P. Saling, BASF SE / Sustainability Strategy; F. Kalberlah, FoBiG GmbH; Q. de Hults, BASF SE; B. Grahl, Fa. Integrall; E. Schmincke, PE-International

Currently, potential toxicological and eco-toxicological impacts of construction products and works are insufficiently characterised. There are no meaningful indicator(s) for a comparative ranking to assist declaration, selection and substitution decisions. At least at present, characterisation models like USEtox have serious limitations to adequately describe potential toxicological and eco-toxicological impacts for a complex life cycle of construction products with heterogeneous exposure conditions from cradle to grave. One reason is the very limited availability of qualified data. However, substance information generated within REACH registration could provide a wealth of useful data to describe health and eco-toxicological impact. Because of the different philosophies of REACH and LCIA characterisation models, it may be difficult to directly make appropriate use of REACH data within LCIA. Therefore, an indicator is proposed, which is applicable in Environmental Product Declarations (EPD) providing additional human health and eco information to LCIA according to ISO 14025. This indicator, "ToxScale", uses REACH information for toxicological and eco-toxicological characterisation of construction products. This paper provides an outline of the ToxScale approach. At this stage, discussion is restricted to human health impact, but may be extended to eco-toxicity. ToxScale is characterised with: 1) a hazard score based on "derived no effect level" (DNEL) 2) an exposure modifier related to the REACH "risk characterisation factor" (RCR), 3) REACH specific descriptors for environmental release categories (ERCs) and process categories (PROCs) to quantify emissions with potential impacts for all stages of a substances' life cycle, 4) an aggregation procedure aggregating along different life cycle stages, and 5) a supplemental procedure to address substances, exposure scenarios, life cycle stages and inherent toxicity, which are not adequately addressed under REACH, but may contribute to the potential impact of a construction product. ToxScale integrates REACH thinking and LCIA thinking as well as "risk" and "hazard" thinking to build an indicator, which permits construction products' ranking based on potential health and eco-toxicological impacts as a supplement to LCIA.

123

### Strategies to deal with information of different reliability exemplified by the use of QSARs to fill the algae data gaps in LCIA of plastic additives

J.E. Grönholdt Palm, Department of Studies in Environmental Science; T.V. Rydberg, M. Rahmberg, IVL Swedish Environmental Research Institute; H. Andersson, IVL Swedish Environmental Research Institute Ltd / Department of Chemical and Biological Engineering; U. Sahlin, Linnaeus University, School of Natural Sciences

Data gaps are problematic when screening for dangerous substances or in impact assessments where several chemicals are considered for evaluation. Lacking testing information can be replaced by non-testing information such as Quantitative Structure Activity Relationships (QSARs), but even though this latter information comes with lower reliability, this is seldom taken into account in the forthcoming assessments. The difficulty to meet standards for best information calls for strategies to handle data gaps which take varying reliability in information into account. Using safety factors when reliability is low can be problematic since this result in more conservative evaluations of substances for which information is of low reliability and an unknown level of risk aversion in the assessment. An alternative is to reflect lower reliability using probability distributions representing the expected error in the information and propagate this uncertainty in the

forthcoming assessments using Monte Carlo analysis. It is even possible to let the error to expect from QSARs depend to what extent a substance falls inside the models domain of applicability. QSARs cannot fill all gaps in data. Default values can be used instead of leaving substances out of assessments, but if so, these should reflect low reliability as well. We demonstrate the practical implications of four strategies to handle varying reliability in information on algal toxicity in a Life Cycle Impact Assessment on 159 plastic additives of concern using emissions from societal plastic materials in Sweden. A review concluded that a small amount of these substances had toxicity data for algae *Pseudokirchneriella subcapitata*. A QSAR was constructed which provided non-testing algal information of substances inside and on the border of the models domain of applicability evaluated by PmodXPS. Substances with neither testing nor non-testing information were assigned default values. Screening based on characterization factors resulted in different rankings of substances when changing the level of cautiousness. The different strategies to handle varying reliability in information do more or less open up for quantifying uncertainty in Life Cycle Impact Assessments.

124

#### **Consensus building results on the new scarcity indicator from WULCA**

A. Boulay, CIRAI - École Polytechnique de Montréal / Chemical engineering department; J.C. Bare, US EPA / National Risk Management Research Laboratory; L. Benini, JRC Institute for Environment and Sustainability - European Commission / Sustainability Assessment unit; M. Berger, Technische Universität Berlin / Chair of Sustainable Engineering Office Z; C. Bulle, CIRAI - ESG - UQAM / Strategy corporate social responsibility; I. Klemmayer, Institute for Water Resources and Water Supply; M. Lathuillière, University of British Columbia; P. Loubet, Veolia Eau d'Île-de-France / UMR ITAP ELSA; A. Manzardo, University of Padua; M. Margni, École Polytechnique de Montréal / Mathematical and Industrial engineering; M. MOTOSHITA, National Institute of Advanced Industrial Sci. and; M. Núñez, UR Laboratoire de Biotechnologie de l'Environnement; T. Oki, University of Tokyo; b. ridoutt, CSIRO; S. Worbe, VEOLIA Environnement Recherche et Innovation / Health and Environment; S. Pfister, ETH Zurich

Recently, the LCA methodology has been used to assess impacts related to water and group them in a new water footprint concept, now framed in ISO 14046:2014. While this document provides principles, requirements and guidelines, no specific impact assessment method is recommended, although several have emerged in the past 5 years. The need for consensus-developed and recommended methods is clear and the challenge was undertaken by the WULCA working group, of the UNEP-SETAC Life Cycle Initiative. Including method developers and experts from different fields, the group is developing consensus-based indicators to assess impacts from water use, complying with the requirements of the ISO document. This work presents the progress of the working group. The work was divided in 6 parts: 1) Identification of the question that the indicator should answer, 2) Identification of the modelling choices and possible options, 3) Consensus findings on each of these modelling choices, 4) Building of the resulting indicator(s), 5) Testing of the resulting indicator(s) and 6) Final recommendation. In order to answer these questions, a series of three expert workshops were held on three different continents: in Zurich (Switzerland), San Francisco (USA) and Tsukuba (Japan), with a total of 48 experts participating. The group agreed that the indicator chosen should answer the following question: "What is the potential of depriving another user of water in this region?", independently of whether the user is human or ecosystem. Consensus finding of these modelling choices and the testing phase is ongoing, and three final possible metrics are presented as the current status of the group's findings based on the following format: 1) Demand-to-Availability ratio (DTA), 2) DTA\*Area/Availability and 3) Area/(Availability – Demand). It is agreed that the final result will consist of a single metric covering the entire globe, modelled at various temporal and spatial scales for application in LCA with different inventory datasets. The resulting indicator and recommendation is expected in Fall 2015. The group is proposing the result of its work and new consensus-based indicator with the hope that it will be adopted widely and hence decrease disparity and confusion when it comes to applying the new ISO standard on water footprinting, by providing an internationally approved, robust and simple indicator for assessment of potential impacts from water consumption.

### **LCA of complex systems: delusion or reality? (I)**

125

#### **Sustainable Product Policies and LCA: experience gained from the development of environmental labelling criteria**

M. Cordella, JRC-IPTS / Sustainable Consumption and Production Unit; O. Wolf, Joint Research Centre - Institute for Prospective Technological Studies / Sustainable Production and Consumption Unit

Type I environmental labels are voluntary programs aiming at identifying environmental superior product options on the basis of pass-fail criteria founded on cycle considerations. The criteria development process typically involves the analysis of complex product systems. This contribution describes experience gained during the development of EU Ecolabel criteria and the role played by Life Cycle Assessment (LCA) in this process. A practical Life Cycle Thinking (LCT) approach based on LCA and complemented by other product-related information

has been applied in this context. LCA plays a core role in the criteria development process for assessing environmental impacts of typical products on the market, identifying life cycle hotspots and evaluating improvement options. Review of the material produced in the literature and development of ad-hoc studies to integrate such information can be functional for the definition of key environmental areas on which to set criteria and for addressing further investigation efforts to find best practices of production and consumption. A complementary product-oriented analysis is necessary to gather legislative, techno-economic and environmental elements that could be not entirely integrated in LCA (e.g. legislative constraints, market and quality of products, inherent safety, indoor air quality, noise emissions) and to identify options which could be used to formulate relevant criteria. In this process, interaction with stakeholders is essential for gathering information and views from experts, pointing out key challenges and solving critical aspects related to the definition of feasible and fair criteria. The outlined approach has been applied to a series of product groups. As illustration, main findings related to the development of labelling criteria for Absorbent Hygiene Products (AHP), which includes products as baby diapers, feminine care pads, tampons and nurse pads, have been reported. The criteria development process involves the analysis of complex systems where LCA plays a core role, although the definition of a coherent set of criteria needs also multi-disciplinary analyses and continuous discussion with experts. LCA can be a powerful instrument for informing policy makers but there are inherent limitations which require critical analysis and certain flexibility for finding a balance between what could be good to do in theory and what can be done in practice.

126

#### **Consequences of changing modelling choices on complex data systems**

G. Wernet,ecoinvent Centre; E. Moreno Ruiz,ecoinvent

In LCA, the choice of goal and scope determines which modelling choices are appropriate for a study. An LCA study also needs both detailed LCI data on the foreground processes and reliable background data. Attributional and Consequential LCA are 2 established modelling approaches which are used in LCA studies today. However, consequential databases have been scarce, and most LCA databases are published following only one specific set of modelling choices, which limits their applicability to studies where the choices are acceptable within the goal and scope definition. This presentation describes a system that allows multiple sets of modelling choices on the same underlying process data. The ecoinvent database version 3.1 is published in 3 system models: Allocation, Cut-Off, Allocation, Point of Substitution (APOS), and Consequential. By comparing the LCIA results of the same LCI database with changing modelling assumptions, the consequences of the modelling choices can directly be observed over a complex system of over 10000 LCI datasets. A comparison of the results over the whole database reveals that in most cases, the choice of allocation method has only minor consequences when comparing Cut-off and APOS. The 2 models can thus form the boundaries for sensitivity analyses of allocation method choices. In comparison, the attributional and consequential models show strong differences in results in many cases. An analysis reveals that 5 common reasons can contribute to differences: the marginal suppliers, activities involving use of or production of many by-products, joint productions and by-products that substitute very harmful or very clean production routes. Here the consequential model offers a further perspective and is the only model suitable for studies where the goal and scope demand a consequential viewpoint. The model is thus a significant improvement for consequential studies. Applying different system models to complex systems offers new analysis options in LCA studies. Studies can profit greatly from 2 different allocation perspectives and a consequential perspective as well. For attributional studies, the choice of allocation approach can be relatively unimportant, whereas the results of attributional and consequential studies often differ a lot. The availability of 2 allocation models and a consequential model, all based on the same underlying data, allows for a better and more thorough understanding of LCA results of complex systems.

127

#### **Needs and Challenges in Life Cycle Assessment of Integrated Energy System**

X. Zhang, Laboratory for Energy Systems Analysis; C. Bauer, Group Environment, Health & Safety; C. Mutel, Paul Scherrer Institute / Laboratory for Energy Systems Analysis

Life Cycle Assessment (LCA) is applied in most applications to assess the environmental impact of an individual product or technology. However in reality, planners and decision makers are often challenged with complex energy systems with multiple technologies for energy generation, demand management, energy supply and storage, further complicated by fluctuating energy prices and system operation conditions. Decisions have to be made not only on the level of individual technologies, but with consideration of techno-economic performance and environmental impact of the entire system as a whole. LCA is a crucial tool to assess the technology interactions and associated environmental impact of such systems, and can generate meaningful and quantitative results that help planners to make more informed decisions. With the definition of integrated energy system, the assessment framework for such system has been developed: procedures for performing integrated energy system assessment have been identified, with focus on addressing the challenges and experience of doing LCA for individual technology and for the entire energy system. Differences in comparison with

conventional LCA applications are discussed in detail. Demonstrations on practical applications are presented using energy technologies explored within the project scope of SCCER-HaE (Swiss Competence Center for Energy Research - Heat and Electricity Storage<sup>[1]</sup>). <br clear="all" /> [1] <http://www.sccer-hae.ch/>

128

### **Integrating LCA and Scenario Modelling of the Energy System for Sustainable Policy-Making**

K. Volkart, Paul Scherrer Institut / Laboratory for Energy Systems Analysis

Today, life-cycle assessment (LCA) is frequently used to support policy-making in strategic decision problems. LCA has been developed for the environmental assessment, i.e. it includes a variety of environmental decision criteria. It typically only addresses single technologies or processes, i.e. lacks the system perspective. Therefore, LCA should be extended or combined with other tools to more comprehensively support policy-makers in their decisions related to complex systems such as the energy system. The energy system can be entitled a complex system considering features such as large-scale integration of new technologies, substitution between energy carriers and electricity grid stability. Additionally, this techno-economic system is embedded in the political and social context (e.g. climate change mitigation, air pollution prevention and energy access). In many countries energy policy-making is at the crossroads: new energy strategies considering the abovementioned societal boundary conditions have to be developed to guide the energy system into a (more) sustainable future. To visualize possible futures, various scenarios have been described and quantified using so-called energy-economic system models. Such models include the whole energy system and its techno-economic characteristics but they do not address other detailed criteria such as those considered in LCA. Therefore, the goal of this work is the development of a methodology for the integration of LCA and scenario modelling. Such an approach combines the system-wide and economic perspective with the detailed technology assessment of LCA. In doing so, LCA information is used to overcome the lack of information on the environmental impacts of the energy policy decisions represented in the scenarios, and thereby allows for more robust decision-making. The proposed methodology is applied and tested in a full-scale energy economic system model. The complete life-cycle burdens of the processes in the energy system are taken into account, i.e. direct emissions, impacts of the construction and dismantling of the infrastructures, and impacts of the materials and fuels used. Also, the underlying heat, electricity and freight transport technology mixes are modelled scenario-dependently. So overall, this work is a novel approach for the use of LCA in the analysis of complex systems that can provide to more comprehensive and more complete information for energy policy-making.

129

### **Top down vs Bottom up to model complex systems: rational and irrational behaviours**

T. NAVARRETE GUTIERREZ, CRTE CRP Henri Tudor / Resource Centre for Environmental Technologies CRTE; S. Rege, Luxembourg Institute of Science and Technology (LIST) / Resource Centre for Environmental Technologies CRTE; A. Marvuglia, Luxembourg Institute of Science and Technology (LIST) / Resource Centre for Environmental Technologies CRTE; E. Benetto, CRP Henri Tudor / Resource Centre for Environmental Technologies CRTE

Consequential LCA (CLCA) seeks an environmental assessment aimed at analysing how physical flows, and thus environmental burdens, vary in response to changes with (marginal or structural) market implications in a specific life cycle, beyond the foreground system. Such changes are normally caused by human driven actions often related to policy or strategic decisions. Human driven actions are generally encapsulated in large systems of interacting actors which can be considered as complex systems. One can distinguish at least two different modelling approaches for complex systems: bottom-up and top-down. Considering revenue maximization as the main driver, we created three models of the complex system of the agricultural sector of Luxembourg: 1) a Top-Down model following a scenario based approach, 2) a partial-equilibrium (PE) model and 3) a Bottom-Up agent-based model (ABM). Each model evaluates the environmental consequences of augmenting maize production by 80000 tons (termed as shock) to generate energy from renewable sources, based on the 2020 target fixed for biogas production of the Luxembourgish Renewable Energy Action Plan. The impact assessment is calculated on the basis of the number of hectares under cultivation for each crop in the system. Undoubtedly the economic driver is the most important in the different decisions of any economic sector. How does a modeler include price discovery in each model as it underpins decision making and hence influences production? For the first two models there is an unambiguous shock (80000 tons of maize) to be imposed on the system. In the ABM, there is no clear consensus on what constitutes a shock, to whom and to what extent. As the presentation will show, the impact assessment results of the models differ. The validity of the first model is based on the expert's experience concerning the marginal replacement crop. The PE model accounts for own and cross-price elasticity of supply depending on exogenous crop prices. The ABM results heavily depend on the validity of the hypotheses of the agent's behaviours. In principle all approaches can account for cropping pattern changes, but the versatility of behavioural responses to shocks and their implications for cropping patterns can be best captured by ABM. The ABM approach has the advantage of including more dimensions with

respect to a completely rational and deterministic approach while providing a top (macro) perspective, useful in decision making.

### **Goal and scope definition in Life Cycle Sustainability Analysis - A context-driven approach**

A. Zamagni, Ecoinnovazione / LCA and Ecodesign Laboratory; P. Masoni, ENEA / LCA and Ecodesign Laboratory; M. Stefanova; C. Tripepi, ENEA

Environmental and Socio-economic analysis of systems requires the use of a framework capable of consistently addressing questions at different level (operational choices, strategic choices; economy wide questions). Moreover the framework shall consider all the relevant mechanisms (cause-effect chains) triggered by the analysed system, measure their effects and express the results in terms of sustainability indicators. Finally, the analysis should be able to integrate empirical facts (i.e.: emissions, resource use, market shifts, etc) with normative positions (i.e.: reduction targets, legal thresholds, value choices). Keeping the life cycle approach and methods as reference, an integration framework for sustainability has been developed, namely Life Cycle Sustainability Analysis (LCSA), which is based on a paradigm consistent with the dictate of the post normal science, and thus is in line with the requirements described above. However, while it has been set up and defined at ontology and epistemology level, it is still not operational [1,2, 3]. The framework recognises the key role of the assessment in the goal and scope definition phase, where the sustainability questions are defined and the mechanisms of the system to be modelled are identified. This paper presents an approach to structure the Goal and Scope phase of the LCSA framework [4], considering the application to the development of a new technology system for the production of high-purity hydrogen from biomass gasification, to be used in fuel cells for automotive transport. The technology is currently being developed in the UNiFHY project, funded by the Fuel Cells and Hydrogen Joint Undertaking (FCH JU) initiative within the 7th Framework Programme of the European Community.

### **Behavior Revised: Examining Behavioral Effects of Contaminants and Other Stressors in Aquatic Animals**

131

#### **A Review of Copper Effects on Fish Behavior**

B.K. Shephard, U.S. EPA / Office of Env Assessment OEA; J. Zodrow, Arcadis U.S., Inc.

Concerns have been raised regarding the potential adverse effects of copper on fish behavior at concentrations lower than U.S. Environmental Protection Agency (USEPA) water quality criteria. To evaluate these concerns, USEPA performed a literature review of copper effects on the behavior of both freshwater and marine fish. Information on the behavior of 58 freshwater and 16 marine fish species was found, with a combined total of 180 LOEC's and 53 NOEC's. Laboratory studies with copper alone, as part of mixtures, and field behavioral studies were all reviewed. Of the 129 LOEC values for laboratory studies with copper only exposures in freshwater, 125 (97%) were higher than the USEPA hardness adjusted chronic copper criterion. All 22 laboratory LOEC's for marine fish exposed to copper alone were higher than the USEPA marine chronic criterion. Avoidance behavior is the most commonly studied endpoint, and is the only endpoint with LOEC's lower than the freshwater chronic copper criterion. Fish avoid copper at low concentrations, but are attracted to copper at higher concentrations. Other behavioral endpoints with available copper effects data include voluntary and involuntary movements, swimming, feeding, social, reproductive and respiratory behaviors. At least for copper, behavioral responses of fish generally occur within a range of copper concentrations comparable to those associated with reproductive and growth effects of copper on fish, meaning the existing USEPA hardness dependent copper criterion is acceptably protective from adverse behavioral effects.

132

#### **Behavioural effects of inorganic mercury on white seabream (*Diplodus sargus*) together with accumulation levels and biochemical changes in eyes and brain**

P. Pereira, Department of Biology and CESAM; J. Raimundo, IPMA / DIVOA; F. Brandão, Biology Department of Aveiro University / CESAM Department of Biology; M. Barata, Portuguese Institute for the Sea and Atmosphere; O. Araújo; V. Cardoso, F. Pinto-Ribeiro, University of Minho / Life and Health Sciences Research Institute ICVS School of Health Sciences; P. Pousão-Ferreira, Portuguese Institute for the Sea and Atmosphere; M. Santos, Aveiro University and CESAM; J. Canario, Instituto Superior Técnico / Centro de Química Estrutural; A. Almeida, Life and Health Sciences Research Institute ICVS School of Health Sciences University of Minho / Life and Health Sciences Research Institute ICVS; M. Pacheco, University of Aveiro / Dept of Biology

Mercury (Hg) compounds have triggered major environmental and human health concerns. Still, there is a knowledge gap on Hg accumulation in brain and eyes of fish, its association with biochemical alterations and related impairments of behaviour. Fish behaviour patterns (i.e. locating food, avoiding predators) are mediated by eyes with an appropriate integration of the central nervous system (CNS). Moreover, those behaviors can be impaired or lost as a result of exposure to Hg. Additionally, no data exist on the ability of those organs to eliminate Hg in a

post-exposure period, as well as on recovery of biochemical endpoints and, consequently, on the reversibility of behavioural syndromes. Current study was designed to mitigate such lack of information by combining the swimming performance of the white seabream (*Diplodus sargus*) together with Hg accumulation and biochemical endpoints (oxidative stress biomarkers and acetylcholinesterase – AChE) in eyes and brain. Fish were exposed to realistic levels of inorganic Hg in water ( $2 \mu\text{g L}^{-1}$ ) during 7 (E7) and 14 days (E14). After that, fish were allowed to recover for 28 days (PE28). The Fulton condition and hepatosomatic indexes did not vary significantly between control and exposed fish along the experiment. At E7, exposed fish exhibited a significant decrease of the first swimming distance, as well as a lower time for refuge. In parallel, Hg levels were significantly higher in brain and eyes, while both activities of AChE and GPx in brain were inhibited. At PE28, previously exposed fish still swam a smaller distance in the first run, exhibited a lower resistance against the water flow (measured as time for the immobility) and lower latency immobility. Accordingly, Hg levels in eyes and brain did not decreased during the recovery period and GSH levels were augmented in brain. Realistic levels of waterborne inorganic Hg can alter fish swimming performance without a rapid reversibility. Such behavioural impairments are in agreement with Hg accumulation in fish brain and eyes, as well as biochemical alterations in brain, which may have repercussions in organism's fitness and survival.

### 133

#### **Sex in troubled waters: The impact of trenbolone on sexual selection in a freshwater fish**

P. Tomkins, Monash University / Biological Sciences; M. Saaristo, Monash University / School of Biological Sciences; M. Allinson, The University of Melbourne / School of Chemistry; B.B. Wong, Monash University / School of Biological Sciences

Sexual selection and female mate choice are particularly sensitive to human-induced environmental change. It has been well established that changes to the visual and acoustic environment can affect the ability of females to choose mates, however the consequences of altering the chemical environment are relatively unknown. Endocrine disrupting chemicals (EDCs) are one group of chemical contaminants with the ability to disrupt sexual selection. A recent surge in interest towards behavioural studies has revealed that EDCs can impact a wide range of behaviours, but their effect on sexual selection and female mate choice is poorly understood. Further, the majority of behavioural ecotoxicological studies have focused on only one group of EDCs (i.e. those with estrogenic properties), while comparatively little is known about the behavioural impact of androgenic EDCs. One androgenic EDC with the potential to affect sexual selection and female mate choice is the androgenic steroid, trenbolone. Trenbolone is a particularly potent compound used to promote growth rates in beef cattle around the world, and has been detected in waterways associated with cattle feedlots. It is known to cause severe morphological and physiological abnormalities, but its impact on sexual selection has yet to be investigated. To address this gap in the literature, we investigated the impact of an environmentally relevant concentration of trenbolone ( $4\text{ng/L}$  – 21 day exposure) on female mate choice in the guppy (*Poecilia reticulata*). When given a choice between trenbolone-exposed and unexposed males, unexposed females were found to prefer unexposed males. However, trenbolone-exposed females showed no preference for either male, suggesting they had lost the ability to discern between males of differing quality. Considering female mate choice plays a pivotal role in maintaining the genetic fitness of a population, the disruption of these mechanisms could have far reaching evolutionary consequences. This is one of the few studies to show that an androgenic EDC can influence female reproductive behavior, and the first to show that androgenic EDC exposure can affect sexual selection and female mate choice.

### 134

#### **Antidepressants alter aquatic predator-prey interactions**

M.L. Hedgesepp, A. Nilsson, O. Berglund, Lund University / Dept of Biology  
Because many antidepressant pharmaceuticals are detected at levels too low to exert direct lethality in the environment, it is necessary to explore those sublethal endpoints, such as changes in organism behavior, that can give rise to effects at the population/community levels. The aim of our work is to determine which effects antidepressants may cause in terms of the ecological interactions among aquatic organisms, namely predator-prey interactions. This work has employed two primary studies based on a model food chain representative of commonly observed predator-prey relationships found in temperate freshwater lakes: 1.) predation of fish (*Perca fluviatilis*) exposed to sertraline upon the zooplankton *Daphnia magna*, and 2.) antipredator responses of fish (*P. fluviatilis*) exposed to sertraline, fluoxetine, or propranolol in response to a simulated piscivore (striking bird model). Results from Study 1 show that feeding rates of exposed fish on zooplankton decreased by ~60% in the two highest sertraline treatments ( $89$  and  $300 \mu\text{g/L}$ ) compared with the control and lowest treatments ( $0.12 \mu\text{g/L}$ ). Additionally, feeding decreased by ~20% in  $0.12 \mu\text{g/L}$  treatments compared with controls at the high prey density only, indicating a marginal effect of sertraline at an environmentally-relevant concentration. Decreases in feeding at both densities indicate alterations in fish foraging ecology representative of decreased search rate and increased handling time. Preliminary results in Study 2 indicate that sertraline has no effect on the type of immediate escape response performed by fish after

being startled by a simulated predator. However, fish exposed to  $300 \mu\text{g/L}$  exhibited a ~15% decrease in initial escape velocity compared with controls, implying the potential for reduced predator avoidance. Analyses of the other compounds are currently in progress, but generally, a reduction of the feeding of fish along with their reduced predator avoidance could lead to detrimental impacts on fish exposed to antidepressants and similar compounds in the environment. Overall, our studies attempt to combine behavioral and foraging ecology with ecotoxicology, providing a vital link to interpreting the effects of environmental contaminants on population and community dynamics. Such data can be used along with the application of simple ecological models for predicting ecological effects at the population/community levels in aquatic systems.

### 135

#### **Bioconcentration of phenanthrene and metabolites in bile and behavioral alterations in the tropical estuarine guppy *Poecilia vivipara***

P.S. Carvalho, A.G. Torreiro-Melo, UFPE Universidade Federal de Pernambuco / Department of Zoology; J. Silva, Sao Paulo State University - UNESP / Eng Ambiental; A. Bianchini, Universidade Federal do Rio Grande - FURG / Instituto de Ciências Biológicas; E.Z. Lamardo, Universidade Federal de Pernambuco  
Quantification of polycyclic aromatic hydrocarbon (PAH) metabolites in fish bile is widely used to evaluate levels of internal PAH contamination in fish, whereas behavioral effects are deemed important to address potential risks to fish populations. The estuarine guppy *Poecilia vivipara* was exposed for 96 h to waterborne phenanthrene at concentrations of 10, 50, 200 and  $500 \mu\text{g/L}$ . Phenanthrene and metabolites in bile were analyzed by fixed fluorescence at 260/380 nm (excitation/emission) wavelengths. Phenanthrene and metabolites increased in the bile of exposed fish in a dose-dependent pattern, and log bile bioconcentration factors ranged from 4.3 to 3.9 at 10 and  $500 \mu\text{g/L}$  phenanthrene, respectively, values that are similar to predicted bioconcentration factors based on phenanthrene  $K_{ow}$ . Swimming resistance index was reduced to 81% of control values at  $500 \mu\text{g/L}$ . Alteration of swimming speed was non monotonic, with a significant speed increase relative to control fish in treatments 50 and  $200 \mu\text{g/L}$  phenanthrene, respectively, followed by a speed decrease in fish exposed to  $500 \mu\text{g/L}$ . The search volume model of fish foraging behavior is based on the idea that the probability of prey detection and capture increases as a predator fish swims faster and therefore for longer distances searching for prey, exploring a larger volume of the habitat for prey. However, in this study the ability of *P. vivipara* to capture prey organisms was diminished in the  $200 \mu\text{g/L}$  phenanthrene treatment where swimming speed increased. Swimming trajectories of fish exposed to 50, 200 and  $500 \mu\text{g/L}$  was altered by the development of a repetitive circular swimming behavior, in contrast to the controls that explored the entire experimental arena. This change in swimming patterns apparently explains the reduction in prey capture rates at  $200 \mu\text{g/L}$  phenanthrene. These results indicate that a change in the pattern of habitat exploration may be more important than changes in swimming speeds to predict consequences to prey detection and capture. The results obtained provide dose-dependent relationships between doses of phenanthrene and metabolites in bile of *P. vivipara* and behavioral effects of greater relevance to the survival and growth of exposed individuals, linking internal exposure with ecologically relevant behavioral effects in the species, which can be of significant utility in studies of environmental monitoring of oil pollution in tropical regions.

### 136

#### **Oil sands process-affected water and fish sensory responses**

K.B. Tierney, M. Reichert, T. Gabruch, University of Alberta / Biological Sciences; B.J. Blunt, University of Alberta / Department of Biological Sciences; B. Sutherland, University of Alberta / Physics; M. Gamal El-Din, University of Alberta / Department of Civil and Environmental Engineering  
Oil sands process-affected water (OSPW) is a complex mixture containing metals, salts, naphthenic acids (NAs) and other compounds. The sensory neurons that fish use to guide so many critically important behaviors are known to be sensitive to metals and salts, but their sensitivity to NAs remains unknown. What we were curious about is whether OSPW and OSPW that had been ozonated (a putative detoxification treatment), constituted an 'odorant' that (1) evoked sensory responses, (2) modified sensory responses to other odorants (i.e. caused olfactory impairment), and (3) evoked behavioural avoidance. Our data suggest that sensory neurons can detect OSPW and ozonated OSPW, that some dilutions of OSPW can impair sensory responses, and that fish may elect to move away from point sources of OSPW. Our findings have implications for both the sensing of OSPW by aquatic vertebrates and the possible impact of OSPW on fish in a natural setting.

#### **Population genomic tools for quantifying evolutionary outcomes and their potential for risk assessment**

E. Turner, Indiana University / The School of Public and Environmental Affairs and The Center for Genomics and Bioinformatics; C. Jackson, N. Keith, Indiana University - Bloomington; S. Glaholt, Indiana University; J. Colbourne, University of Birmingham; J.R. Shaw, Indiana University / The School of Public and

Environmental Affairs and The Center for Genomics and Bioinformatics

Differences in inter-individual response are described by variation in environments and genomes that combine to give rise to phenotypic variation observed in populations. Population genomics provides tools for understanding these features that provide a link to phenotype and could be useful to risk assessors. In this talk we draw from recent population genomic studies to explore how toxicant exposure contributes to genome variability, influences the fate of genome variation in populations, and over micro-evolutionary time scales determines the fate of phenotypes within populations. These studies contribute to and make use of a maturing genomic tool kit for *Daphnia pulex*, that includes array comparative genomic hybridization (aCGH) and full-genome re-sequencing of over 50 individuals. Using this model of structural variation we report exposure-induced alterations in the magnitude and distribution of gene copy number (CNV) in natural populations. We reveal a method for measuring the contribution of this environment induced genome variation on phenotype, and through spatial and temporal studies determine that CNV play a major role in establishing the environmental stress-response of a population. Finally, we discuss the importance of understanding genome variation and the evolutionary forces that shape it, and demonstrate how population genomic tools can be used to quantify the evolutionary forces acting on populations so that they could potentially be applied to risk assessment.

138

#### **Chronic radiation exposure in plant populations: from molecular to population effects**

S.A. Geraskin, Russian Institute of Radiology and Agroecology / Radioecology

The consequences of long-term chronic exposure to low pollutant concentrations is neither well understood nor adequately included in risk assessments. To understand effects of real-world contaminant exposure properly we must pay attention to what is actually going on in the field. However, for many wildlife groups and endpoints, there are no, or very few, studies that link accumulation, chronic exposure and biological effects in natural settings. To fill the gaps, results of field studies carried out on different plant species (winter rye and wheat, spring barley, oats, Scots pine, wild vetch, crested hairgrass) in various radioecological situations (nuclear weapon testing, the Chernobyl accident, uranium and radium processing) to investigate effects of long-term chronic exposure to radionuclides are discussed. In spite of high heterogeneity in response, we have detected several general patterns. Plant populations growing in areas with relatively low levels of pollution are characterized by the increased level of both cytogenetic alterations and genetic diversity. Accumulation of cellular alterations may afterward influence biological parameters important for populations such as health and reproduction. Presented data provide evidence that in plant populations inhabiting heavily contaminated territories cytogenetic damage were accompanied by decrease in reproductive ability. In less contaminated sites, because of the scarcity of data available, it is impossible to establish exactly the relationship between cytogenetic effects and reproductive ability. Contamination of the plants environment activates genetic mechanisms, changing a population's resistance to exposure. However, there are ecological situations in which enhanced resistance has not evolved or has not persisted. Consequently, there are good theoretical and practical reasons for more attention being paid to the mechanisms by which populations become more resistant and to those situations where adaptation appears not to be taking place. Since adaptation plays an important role in response of populations on radiation exposure, this process needs to be incorporated into management programmes. To this very day, the effects of chronic exposure on living organisms and populations remain poorly explored, and represent a much needed field of research.

139

#### **Long-term effects of metal pollution in freshwaters: can genetic diversity of Chironomid populations be an indicator of environmental quality?**

J.A. Pedrosa, CESAM / CESAM Department of Biology; A.L. Machado, University of Aveiro / CESAM Department of Biology; B. Cocchiarraro, Senckenberg Research Institute; D. Campos, Department of Biology and CESAM; A.M. Soares, Universidade de Aveiro / Department of Biology and CESAM; C. Nowak; J.L. Pestana, CESAM & University of Aveiro / Department of Biology and CESAM

Anthropogenic pollutants are well-known selective pressures with the potential to cause detrimental consequences to the long-term viability of freshwater biota. Environmental risk assessments are usually based on standard laboratory tests which evaluate potential harmful effects of pollutants on a limited number of model species under controlled conditions. Although being critical for ecotoxicological evaluation of chemicals, results are difficult to extrapolate to natural conditions and thus limit the assessment of natural ecosystems' health. Moreover ecological indicators, based on assemblages of species are useful for monitoring the quality of freshwaters but fail to address important questions related to the dynamics and future ecological condition of aquatic ecosystems. For example, do anthropogenic stressors alter the genetic diversity of natural populations? If so, is there any associated fitness cost that affects the ability to cope with environmental changes? Are some populations adapted to anthropogenic stressors? During the last decades there has been increased interest in the application of population genetic markers in an ecotoxicological context. It is believed that depending on the duration and intensity of pollution, reductions of genetic diversity may occur in natural

populations inhabiting polluted areas as a consequence of changes in population structure. Because the ability of natural populations to adapt to pollution is directly related to the amount of genetic diversity, contaminant-driven genetic erosion may counteract potential genetic adaptation and threaten the long-term viability of populations under environmental changing conditions. Therefore, genetic diversity as an indicator of environmental condition may add value to ecological risk assessment. Although numerous laboratory and field works have studied the effects of contaminant exposure on levels of genetic diversity in aquatic organisms, there are still limited evidences on how genetic diversity measures correlate with other ecosystem level indicators such as biotic indexes. In order to evaluate the applicability of genetic diversity measurements as ecological indicators, we investigated how historical metal pollution affected genetic diversity of natural populations of *Chironomus riparius*, if there was evidence of increased tolerance to metals and if levels of genetic variation were correlated with macroinvertebrate structural and functional diversity.

140

#### **Chronic depleted uranium exposure impacts DNA methylation in zebrafish**

K. Gombeau, Institut de Radioprotection et de Sûreté Nucléaire / PRPENVSERISLECO; S. Pereira, IRSNPRP-ENV / SERISLECO; J. Ravanat, CEA Grenoble; V. Camilleri, Laboratoire de Radioécologie et d'Ecotoxicologie, Institut de Radioprotection et de Sûreté Nucléaire; I. Cavalie, IRSN; J. Bourdineau, Université Bordeaux; C. Adam-Guillermin, IRSN

Among environmental pollutants, uranium (U) is an actinide naturally present in the environment. The (eco)toxicity of this metal has been well studied, but, despite the large amount of knowledge accumulated until there, some are lacking, and particularly how U impacts gene expression and the possible risk in a transgenerational context. Many factors, as the appearance of DNA mutations play a role in the aetiology of several biological dysfunctions, but these factors also include the chemical modifications of the DNA (without changes in the sequence) and its proteic environment together called "epigenetic modifications". DNA methylation is the epigenetic mechanism which has been the most studied and is known to be highly related to gene expression. In this context, we decided to study DNA methylation patterns induced by a chronic exposure to environmental concentrations of depleted uranium to evaluate the possible link with the effects already observed on gene expression in freshwater model, *Danio rerio*. In order to better characterize environmental problematic of uranium contamination, male and female zebrafish were exposed separately to two environmentally relevant waterborne concentrations of depleted uranium (DU) : 2 and 20 µg.L<sup>-1</sup> during 24 days. DNA methylation was assessed using MS-AFLP, method based on the difference in sensibility to cytosine methylation between two endonucleases which share the same cleavage site (5'-CCGG-3'), *Msp* I and *Hpa* II. Global methylation levels measured throughout the experiment revealed that DU induced gender-specific hypomethylation patterns which were mostly found in exposed males, with a strong dose-dependent impact, and particularly, the highest decreases were observed for those exposed to 20 µg.L<sup>-1</sup>. Impacts on methylation patterns were not related to the intra-tissular concentration of U. These results highlight for the first time that environmentally relevant concentrations of DU can induce modifications of DNA methylation in the freshwater model *Danio rerio*. The hypomethylation of enzymes recognition sites occurred mostly in exposed males in a dose-dependent manner and revealed a gender-specific response to DU contamination. As DNA methylation is impacted in gonads, these patterns of modifications could be transmitted to the offspring, impacting its development. Furthermore, to determine if it impacts sequences involved in genes expression, we plan to study DNA methylation by MeDIP-Chip analysis.

141

#### **Multigenerational effects of contaminants in D. magna. Effects of offspring quality**

C. Barata, CSIC / Environmental Chemistry; B. Campos, IDAEA-CSIC / Environmental Toxicology; R. Jordão, Biology; M.F. Lemos, Instituto Politécnico de Leiria / Dept Biology; A.M. Soares, Universidade de Aveiro / Department of Biology and CESAM

Most ecotoxicological test guidelines are only considering effects within one generation, thus potential detrimental effects across generations, if any, are under evaluated. The aim of this present study is to set up a protocol to perform a multigenerational ring test using the existing guidelines for the *Daphnia magna* reproduction test. One of the most important factors to be considered is when the second generation starts. It is well known in ecology that the size and quality of offspring varied across the first clutches in *D. magna* and that certain chemicals affect offspring quality. Multigenerational effects were evaluated using three contaminants nonylphenol, piperonyl butoxide (PBO) and tributyltin (TBT). In all three chemicals chronic toxic effects on reproduction were more pronounced in the second generation. Life-history analyses showed that the studied chemicals affected the quantity and quality of the offspring produced by exposed females and a result when those offspring was further exposed showed greater sensitivity than the parental generation. These results are in line with those obtained in multigenerational studies in mammalian tests that evidenced that in most cases effects on the second generation can be predicted evaluating the quality of the offspring produced. Acknowledgement-This project was supported by the Spanish MEC grant CTM2011-30471-C02-01. The Portuguese Foundation for Science and

## Metabolomics and Pollution Sourcing: Molecular Markers in the Field

142

### Metabolomics reveals a perturbation to kairomone chemical messengers in ZnO nanoparticle exposed *Daphnia magna*

N.S. Taylor, Wilfrid Laurier University / Biology; J. Sostare, University of Birmingham; F. Fabrega, Universitat Rovira i Virgili / Chemical engineering department; U. Sommer, University of Birmingham; R. Merrifield, University of Birmingham / geography earth and environmental sciences; J. R. Lead, University of South Carolina / Center for Environmental NanoScience and Risk; C.R. Tyler, Biosciences College of Life and Environmental Sciences; M.R. Viant, University of Birmingham / School of Biosciences

Zinc oxide nanoparticles (ZnO NPs) are one of the most widely used nanomaterials, applied in consumer products from cosmetics to electronics. Nevertheless, our understanding of their aquatic toxicity is limited, although it is speculated to arise from dissolution of  $Zn^{2+}$  from the NPs. Metabolomics, the study of the small molecule composition of biological samples, is a proven approach for discovering metabolic responses to toxicants. We exploited the non-targeted capabilities of metabolomics to investigate the molecular toxicity of waterborne ZnO NPs to *Daphnia magna*. Mass spectrometry based metabolomics showed a dose-dependent metabolic response to the NPs, orthogonal to the effects of bulk ZnO and  $Zn^{2+}$  (aq). Detailed investigations, including MS/MS for metabolite identification, revealed that families of aliphatic sulfates and sulfamates were significantly decreased (up to 10-fold) following ZnO NP exposure. Some of these compounds have previously been shown to act as kairomones; chemical messengers emitted by the *Daphnia* that benefit another species without benefitting the emitter. Kairomones released by the daphniids are sensed by some algal species, which subsequently alter their morphology in direct response to this predation threat. Using the unicellular alga *Desmodesmus subspicatus*, we have replicated this morphological response to the kairomones of healthy *D. magna*, and more importantly have shown a modulation of this algal morphological response following exposure of *D. magna* to ZnO NPs. In addition, we have used several imaging modalities to reveal the uptake of ZnO NPs into the *Daphnia* gut and associated cellular perturbations that underpin this toxicity. Collectively these discoveries represent a novel NP-biota interaction with currently uncharacterised ecological consequences. Here we present the draft mapping of this nanotoxicological effect onto an adverse outcome pathway framework that spans two trophic levels.

143

### <sup>1</sup>H NMR-based metabolic profiling reveals tissue-specific responses to mercury toxicity in wild fish *Liza aurata*

T. Cappello, University of Messina / Biological and Environmental Sciences; P. Pereira, Department of Biology and CESAM; M. Maisano, University of Messina; J. Raimundo, IPMA / DIVOA; A. Mauerci, University of Messina / Biological and Environmental Sciences; M. Pacheco, University of Aveiro / Dept of Biology

Among the heavy metals, mercury (Hg) is a hazardous pollutant due to its persistence, bioaccumulation, toxicity to organisms, and subsequent ecological risk. In order to elucidate the toxicological responses induced by Hg in fish, an environmental metabolomics approach was applied in golden grey mullet *Liza aurata* collected from a Hg impacted area of the Ria de Aveiro, Portugal (Laranjo, LAR), and a reference site not known to be polluted by Hg (São Jacinto, SJ). Physico-chemical parameters were measured at both sites. Total Hg (tHg) and methylmercury (MeHg) were measured in water and sediment samples, and confirmed that LAR is a highly Hg contaminated area. In liver and gills of fish from LAR, higher levels of tHg and MeHg were found in respect to SJ, evidencing an Hg exposure. Also, tHg and MeHg accumulation were respectively 10-fold and 17-fold higher in liver than gills. <sup>1</sup>H NMR spectroscopy and chemometric analysis were applied on fish liver and gills. The metabolic profiles of liver were dominated by taurine and glycerophosphocholine, while gills by taurine and lactate, and several other major classes of compounds were detected. PCA score plots described the majority of variance between spectra (i.e. 78% in liver and 71% in gills) and clustered samples with similar metabolite profiles, clearly separating the two fish groups. The metabolic profile of livers revealed increased phosphocholine and glycerophosphocholine, suggesting perturbation in osmoregulation; increase in hepatic glucose indicating glycogenolysis; and reduction in amino acids resulting in changes in protein metabolism as activation of cytoprotective mechanisms, as supported by depletion in uracil for transcriptional activities, and increase in glutathione and glutamate involved in oxidative stress defence. In gills the elevated choline level may result in alteration of lipid metabolism; increase in creatine suggests an adaptive ionoregulation; increases in lactate and fumarate may indicate enhancement in anaerobic metabolism, while the elevation in amino acids may indicate the occurrence of protein catabolism. Noteworthy, in gills depletion of glutathione was observed. Overall, environmental metabolomics enabled an integrated description of the Hg-induced metabolic responses in *L. aurata*, and an assessment of the differential Hg accumulation and tissue-specific toxicological

mechanisms elicited in fish liver and gills, attributable to their differential physiological functions.

144

### Characterization of fluvial biofilm exposed to multi-stress conditions using a metabolomics approach

A. Serra, Water Quality; D.A. Muñoz, Catalan Institute for water research (ICRA) / Water Quality; N. Corcoll, Department of Biological and Environmental Science; B. Huerta Buitrago, Catalan Institute for Water Research (ICRA) / Department of Water Quality; S. Rodriguez-Mozaz, Institute for Water Research (ICRA) / Water Quality; s. sabater, Universitat de Girona; D. Barcelo, IIQAB-CSIC / Institute for Environmental Assessment and Water Research

Rivers are subjected to many stress factors; some of them have a natural origin like the drought, and some others are due to anthropogenic pollution, such as emerging contaminants, including pharmaceuticals. Although the effects of pharmaceutical compounds on aquatic organisms have been previously evaluated in several studies<sup>1</sup> the response at community level (i.e. biofilm community), has been scarcely investigated. Besides, biological communities are often exposed to multiple stressors simultaneously. For instance, Mediterranean streams commonly have a period without flow in summer months and communities are exposed to a drought, impacting their function and structure<sup>2</sup>. In this context it becomes relevant to evaluate the response of the aquatic community to both, single stressors and combination of multiple ones. Therefore, the aim of this study was to investigate the metabolic response of biofilm community exposed to a pharmaceuticals mixture and/or to a dry period in order to identifying endogenous biofilm's metabolites that can be altered by these stress factors. The experiment was carried out in artificial streams where the biofilm was exposed to a dry period (a week without flow), and to a mixture of nine pharmaceutical compounds (ibuprofen, diclofenac, carbamazepine, sulfamethoxazole, erythromycin, metoprolol, atenolol, gemfibrozil, hydrochlorothiazide) at environmental relevant concentrations. In order to characterize the biofilm response, a metabolomic approach was done using liquid-chromatography coupled to mass spectrometry, LTQ-orbitrap. Results indicate a significant metabolome change in the biofilm exposed to a dry period and slight differences in the biofilm exposed to pharmaceuticals. Most of the compounds altered due to a dry period were lipids including behenic acid and lignoceric acid; but also levels of pigments like harderoporphyryr changed. In the case of pharmaceuticals exposure, lipids were also the main group of compounds identified. When both stressors were applied at the same time the response of biofilm was similar to that expressed only in the dry period pinpointing this factor as the most relevant stressor. The metabolomic approach allowed the identification of different putative compounds underlying these stress factors and belonging mainly to the lipids group that could be proposed as biomarkers of exposure.

145

### Effects of global climate change on *Daphnia magna* metabonomics studied by GC-MS and chemometric tools

E.G. Garreta, IDAEA CSIC Barcelona / Environmental Chemistry; B. Campos, IDAEA-CSIC / Environmental Toxicology; J. Bayona, IDAEA CSIC / Environmental Chemistry; C. Barata, CSIC / Environmental Chemistry; S. Lacorte, IDAEA-CSIC / Environmental Chemistry; R. Tauler, IDAEA-CSIC

Climate change is a current concern for the scientific community, demanding novel information about the effects of environmental stressors on living organisms. Metabolomics approach tries to characterize the most relevant metabolites which have suffered changes in response to an external agent. *Daphnia magna* is a model organism highly used for toxicological assessment in aquatic media, although few metabonomic studies have been performed up to now. The aim of this work is to study the metabolic variation of *D. magna* individuals exposed to changes of three different abiotic factors: salinity, temperature and oxygen levels, and to achieve a tentative identification, using advanced chemometric tools. An untargeted gas chromatography method coupled to mass spectrometry (GC-MS) was developed to evaluate these effects. Polar metabolites of the whole organism were extracted by a methanol-water solution and the chromatographic separation was performed with optimization of derivatization conditions. PCA analysis of Total Ion Chromatogram has shown major changes in metabolite levels of *Daphnia* exposed to salinity and temperature. PLS-DA of the same data set together with their class assignment according to the sample treatment and Variables Importance in the Projection (VIP) scores revealed the most influent variables on the discrimination among controls and treated samples. Resolved MCR-ALS components in the analysis of the full scan GC-MS data enabled a tentative identification and confirmation of possible metabolic biomarkers of exposure. Metabolite identification through the NIST2014 mass spec. ref. library, allowed the description and proposal of the more important altered metabolite pools caused by the studied effects in *Daphnia* metabolome. As a preliminary conclusion, the increase of salinity is shown to affect the carbohydrate and amino acid levels while temperature affected mostly amino acids. Due to the large datasets generated from full scan GC-MS analysis and to their complexity, different chemometric data analysis approaches were used to extract the information contained in the experimental data sets and to identify the more important metabolites affected by the exposure to the previously mentioned physical agents. This integrated approach allowed the resolution of the untargeted complex GC-MS full scan data sets increasing the amount of information recovered and maximizing the interpretation of their biological significance.

### Chemical and microbial MST tools: discrimination of faecal sources in shellfish-harvesting or bathing areas and their catchments in France

E. Jarde; L. Harraut, CNRS UMR Geosciences Rennes; E. Quenot, IFREMER / Department RBE; L. Jeanneau, CNRS UMR Geosciences Rennes; S. Lozach, IFREMER / Department RBE; P. Petitjean, CNRS UMR Geosciences Rennes; C. Marin, M. Gourmelon, IFREMER / Department RBE

The microbiological quality of shellfish-harvesting areas and bathing areas can be affected by faecal pollution from human or animal sources. In recent years, numerous microbial source tracking (MST) methods based on quantification of microbial and/or chemical compounds have been developed for differentiating between sources of contamination. Indeed, identifying and managing microbial water quality at the watershed scale is extremely challenging for effective resource management and remediation. In our study, the relevance of three host-associated real-time PCR *Bacteroidales* markers (HF183, Rum2Bac, and Pig2Bac) and faecal stanols as MST markers was assessed at the level of three catchments in Brittany, France. They were monitored together with faecal indicators (*Escherichia coli* and enterococci) and chemophysical parameters (rainfall, temperature, salinity, pH, and turbidity) by monthly sampling over 1 year (n=180 water samples). Concentrations of *Escherichia coli* varies from  $E.coliE.coli > 1,000$  CFU/100 ml). Among the 180 water samples analysed, MST markers have assigned an origin of faecal contamination in 161 samples (89%). Host-associated *Bacteroidales* markers and faecal stanols assigned a least one similar origin in 109 water samples. In these 109 samples, *Bacteroidales* and faecal stanol assigned a bovine origin in 54% of the samples and a human origin in 39% of the samples. The porcine faecal contamination of the water has been assigned in 7% of the samples analysed. MST markers selected in this study showed that faecal contamination in water was mainly from bovine origin in these three catchments. Those results are in agreement with the landscape occupation and management. Overall results provide important information on the origin of pollution and for hazard evaluation. These data are very useful to identify sources of pathogens such as *Salmonella*, *Campylobacter* or pathogenic *E. coli* which could be present in some of these water samples. This study has been partially fund by the European Regional Development Fund Interreg IVA Program.

## Metals in the Environment: Fate, Speciation and Bioavailability in Water, Soil and Sediment (III)

147

### Uptake and intracellular distribution of trivalent and hexavalent chromium in a freshwater algae

I. Aharchaou, LIEC; D.A. Vignati, CNRS / LIEC UMR; E. Battaglia, University of Lorraine LIEC CNRS UMR; F. Liu, The Hong Kong University of Science and Technology; C. Fortin, University of Quebec / Centre Eau Terre Environnement

In surface waters, chromium occurs mainly in two oxidation states, namely Cr(III) and Cr(VI). These oxidation states have different chemical features and can be internalized and distributed in organisms in different ways. While Cr(VI) is known to cross the cellular membrane via the sulfate uptake pathway, the uptake mechanism of Cr(III) is not well known. Cr(III) is considered less harmful than Cr(VI) to aquatic organisms, however, the bioavailability and toxicity of Cr(III) may be underestimated. In this study, uptake experiments were performed between pH 5 and 7. At each pH, uptake rates of Cr(III) and Cr(VI) by *Chlamydomonas reinhardtii* were measured at different concentrations within the range 1 nM and 10  $\mu$ M. In parallel, the subcellular distribution of Cr(III) and Cr(VI) in the green alga *C. reinhardtii* was determined in algal cells exposed for 72 h to either 100 nM Cr(III) or Cr(VI) using a homogenization protocol and a differential centrifugation approach. Results showed that the internalization rate Cr(III) increased with the concentration of Cr(III) (from 1 nM to 10  $\mu$ M) and was higher at pH 7 than at pH 5 or 6. This may be partly explained by a competition between the Cr(III) and  $H^+$  for internalization sites, although we suspect that the formation of hydroxo-complexes may contribute to the overall metal uptake flux. Metal uptake profiles suggest the presence of possibly two transporters involved in the uptake of Cr(III) at pH 5 and 6 while only one was observed in the concentration range tested at pH 7. The protocols for the study of the intracellular distribution of Cr(III) and Cr(VI) in *C. reinhardtii* algae have been developed and experiments are currently underway. Little knowledge exists about the chemical forms that control the accumulation of Cr(III) by algae, nor on the intracellular distribution of Cr in algae exposed to Cr(III) and Cr(VI). We hypothesize that Cr(III) and Cr(VI) have different fate within the cells. The subcellular distribution experiments will help to probe the detoxifying mechanisms and infer on the potential for trophic transfer of the two Cr redox forms. **Keywords:** Chromium, uptake, subcellular distribution, speciation.

148

### Algal uptake, toxicity and subcellular distribution of rare metals (Pd, Pt, La, Eu)

C. Fortin, University of Quebec / Centre Eau Terre Environnement; K. Racine, Centre d'expertise en analyse environnementale du Québec; C. Beaubien, G. Tétrault, Institut National de la Recherche Scientifique / Centre Eau Terre Environnement; S. Leguay, INRS-ETE; P.G. Campbell, Université du Québec,

INRS / INRS Eau Terre Environnement

Until very recently, little attention has been given to the ecotoxicology of platinum group elements (PGEs) and rare earth elements (REEs). Despite a recent spurt of publications on PGEs, there are still few data available for risk assessment purposes (exposure and effects). A similar lack of ecotoxicological data exists for REEs. Of particular concern is the poor solubility of lanthanides in the presence of phosphate. The toxicity of Pd and Pt was evaluated using the unicellular green alga *Chlamydomonas reinhardtii* while the toxicity of La was determined with *Chlorella fusca*, an alga known to accumulate enough phosphorus to sustain its growth for several days in phosphate-free media, thus avoiding the precipitation of REEs. To examine the cells' capacity to detoxify these metals and to assess their potential for trophic transfer, we performed a subcellular partitioning scheme on metal-laden *C. reinhardtii* cells. This requires homogenization of the cells using an ultrasonic probe followed by differential centrifugation and heat denaturation steps, resulting in five fractions: cell debris, metal-rich granules, organelles, heat-denatured cytosolic proteins (HDP), and heat-stable peptides or proteins (HSP). The most sensitive endpoint for *C. reinhardtii* was thus the cell population after 24 h and resulted in EC50s of  $66 \pm 3$  nM total Pd and  $26 \pm 36$  nM total Pt at pH 7.0. In the case of *C. fusca*, the final yield after five days resulted in an EC50 of  $440 \pm 60$  nM (based on the free calculated  $La^{3+}$  and on the average total measured La; pH = 5.5). Finally, in order to test for the influence of speciation, several ligands were used (iminodiacetate, nitrilotriacetate and malate) and showed that accumulation and toxicity can be predicted based on the free  $La^{3+}$  ion concentration. Clear differences were observed in the metal subcellular distribution between the "hard" (La, Eu) and "soft" (Pd, Pt) metals. The soft Pd and Pt were mostly found in the organelles and HSP fractions while the hard La and Eu mostly ended up in the granules fraction. These results are coherent with the observed toxicity of these elements. The high tolerance of algae to the two REEs and their high relative abundance in the granules fraction suggest a high capacity to sequester these elements. On the other hand, the two PGEs induced growth inhibition at very low concentrations and were mostly found in the sensitive organelles fraction.

149

### Limited between-population variability of metal bioaccumulation in Gammarus populations from uncontaminated freshwaters

N. Urien, O. Geffard, Irstea; L.C. Fechner, Irstea Antony / UR HBAN; E. Billoir, Rovaltain Research Company; a. chaumot, Irstea / UR MALY Laboratoire Ecotoxicologie; J.D. Lebrun, Irstea

An active biomonitoring approach, based on transplantation of *Gammarus*, has been developed to assess trends of bioavailable metal contamination in freshwaters in France. From this approach, Besse et al. (2013) proposed for each metal a threshold value of contamination in gammarids above which measured concentrations are expected to reveal a bioavailable contamination at the sampling site. However, transplantation is based on organisms collected from one control population, ignoring the complexity of the environment. Populations settle in contrasted environments in terms of physicochemistry and contamination levels to which they could have been acclimated. This local acclimation may lead to physiological changes likely to affect metal regulation mechanisms and consequently metal accumulation patterns between populations. The between-population bioaccumulation variability is unknown and need to be assessed because it questions the relevance of biomonitoring strategies and the use of gammarids as test organisms for environmental monitoring. The aim of this study was to investigate the metal bioaccumulation abilities of different naive populations of freshwater gammarids. By this way, we sought to assess the natural range of bioaccumulation abilities between unexposed populations of gammarids. Five naive *Gammarus* populations from natural freshwaters exhibiting various physicochemical characteristics were collected and then exposed, in the laboratory, to various metal concentrations (Pb, Cd and Ni) for seven days followed by a seven-day depuration period. The internal metal concentrations in gammarids were measured over time. Then, metal uptake and elimination rate constants describing bioaccumulation were determined for each population, using biodynamic model approach. Results show that naive populations have a generic response to metal exposures which support the ecotoxicological relevance of their use as biomonitoring tool. This generic response gives interesting perspectives towards a generalised use of gammarids as bioindicators of water quality. The quantification of the natural variability in *Gammarus* and its use as reference can offer also the opportunity to assess another confounding factor affecting bioaccumulation, as chronically exposure to contamination.

150

### Whole body metal concentrations in aquatic macroinvertebrates: mechanistic and correlative modelling

D. Hug Peter, Institut Forel, University of Geneva / Section of Earth and Environmental Sciences Institute Forel and Institute for Environmental Sciences; V.I. Slaveykova, University of Geneva / Section of Earth and Environmental Sciences Institute Forel and Institute for Environmental Sciences; E. Castella, University of Geneva / Institute Forel Earth and Environmental Sciences and Institute of Environmental Sciences

Whole body metal concentrations in aquatic macroinvertebrates convey a valuable starting point to investigate the link between environmental conditions, uptake and toxicity. Despite advances in the understanding of uptake and bioavailability, they

remain hard to interpret and hard to predict from environmental conditions. In this study, field data was collected for two different approaches: 1. test the ability of existing biodynamic parameters to predict whole body metal concentrations in aquatic macroinvertebrates in model species and closely related taxa; and 2. develop a multiple regression model to predict metal accumulation in macroinvertebrates from concentrations in water and sediment. Whole body metal concentrations of a broad range of aquatic macroinvertebrates and concentrations of metals in water, sediment and suspended particulate matter of all sites were used in both models. Whole body concentrations estimated with the biodynamic model were within the measured range of concentrations for Cd in *L.stagnalis* and *D.polymorpha*. For Cu, values were systematically underestimated. When transferred to other gastropod species, the *L.stagnalis* model predicted whole body concentrations for Cd in the same order of magnitude as measured concentrations but the accuracy of the results was poor. Preliminary results of the correlative approach were promising. The models for different metals were able to explain 25 to 70 % of the variance (adjusted R<sup>2</sup>). The significant parameters conveyed information on different uptake mechanisms. Preliminary prediction trials showed that the influence of environmental conditions and of different types of taxa needs to be tested further to improve predictive power. Overall, the study confirmed that both techniques have advantages and pitfalls and that the adaptation of models to different species and environmental conditions remains challenging.

#### **The speciation of Cu and Zn in two hyperaccumulator estuarine oysters: a synchrotron study**

Q. Tan, Xiamen University - College of the Environment & Ecology; Y. Wang, Shanghai Synchrotron Radiation Facility; W. Wang, Hong Kong University Sci. Technol. / DIVISION OF LIFE SCIENCE

The speciation of Cu and Zn were studied in two hyperaccumulator estuarine oysters, i.e., *Crassostrea hongkongensis* and *Crassostrea sikamea*, using synchrotron techniques, including the X-ray-absorption near-edge structure (XANES) and the extended X-ray absorption fine structure (EXAFS). The two techniques corroborated each other and provided consistent speciation information. Lower proportion of tissue Cu and Zn were found as sulfur-bonded (thiolate) species, which was replaced by oxygen- or nitrogen-bonded species, in the contaminated oysters than in the normal ones. In the gill of normal *C. hongkongensis*, Cu and Zn occurred mainly in species resembling cysteine complexes; in the gill of contaminated ones, the major metal species resembled histidine complexes or phosphates. Speciation of Cu and Zn in mantle was similar to that in gill, both of which were different from that in digestive gland. Even in the digestive gland of heavily contaminated *C. hongkongensis*, the proportion of thiolate species was still substantial. In *C. sikamea*, the contrast in metal speciation between normal and contaminated individuals was similar to but much less pronounced than that in *C. hongkongensis*. Cu existed in different oxidation state when bonded with different atoms, i.e., as Cu(I) when bonded with sulfur, and as Cu(II) when bonded with oxygen or nitrogen. This study provided direct and semi-quantitative information on the changes of metal speciation in contaminated oysters, indicating that in metal-rich environments oysters could efficiently detoxify excessively accumulated Cu and Zn by storing them in oxygen- and nitrogen-bonded complexes.

#### **Response of *Crassostrea rhizophorae* to metal and metalloid environmental contamination: Integrating Chemical and Biological Data by Chemometrics**

Ld. Souza, Ciencias Fisiológicas; M. Morozesk, UFSCar / Departamento de Ciências Fisiológicas; M. Bonomo, Universidade Federal do Espírito Santo / Departamento de Ciências Biológicas; V. Azevedo, Universidade Federal de São Carlos; M. Monferran, Universidad Nacional de Córdoba; S. Matsumoto, C. Milanez, Universidade Federal do Espírito Santo; D.A. Wunderlin, Universidad Nacional de Córdoba / ICYTAC DPTO QUÍMICA ORGÁNICA FACULTAD DE CIENCIAS QUÍMICAS; M.N. Fernandes, Univeridade Federal de Sao Carlos / Ciencias Fisiologicas

In this study, chemical and physical parameters were analyzed in two Brazilian estuaries, Vitoria bay (sites: Santa Maria, Serra and Lameirão) and Santa Cruz bay impacted by metal contamination, to assess the bioavailability of metals and their accumulation in the soft tissue of the oyster *Crassostrea rhizophorae*. Levels of B, Al, Cr, Mn, Fe, Ni, Cu, Zn, As, Se, Ag, Cd, Pb and Hg in surface water and oyster soft tissue were correlated with exposure and biochemical biomarkers and histopathological change indexes in the gills. The use of physical and chemical analysis integrated with biomarkers provided cause and effect data of environmental conditions and metal contamination in the resident organisms. The GPA analysis allowed the observation of a seasonal difference in Santa Maria and the rain influence in areas with high riverine input. This method, when integrated with biological data showed a high efficacy in area differentiation, showing that biological alterations are correlated with environmental physical and chemical conditions. In addition, the biochemical mechanisms were effective in metal elimination, especially metallothionein, while the oyster morphology were affected mainly by environmental data, such as salinity. **Keywords:** estuary, histopathology, oyster, antioxidant system.

#### **Bismuth in cosmetic products and its implications for sewage sludge management**

J. Amneklev; L. Sorme, Statistics Sweden / Environment and tourism; A. Augustsson, Linnaeus University; B. Bergback, Linnaeus University / School of Natural Sciences

Bismuth (Bi) is a heavy metal that over recent years has shown increasing concentrations in sewage sludge in Swedish wastewater treatment plants (WWTPs), indicating an increasing Bi use in the society. The high accumulation rate of Bi in soil when sewage sludge is used as fertilizer on arable land is of environmental concern. Bismuth is used in various consumer products to replace lead, but which sources in the society that explain the increasing amount of Bi in sewage sludge in the municipal WWTPs is however unknown. This study aimed to analyze one product group suspected to contain Bi, cosmetics, and three different products were chosen (foundation, powder and eye shadow) in order to study the flows in urban wastewater in Stockholm, Sweden. The chemical analyses showed that Bi was present in very high concentrations (>100 000 mg/kg) in one third of the analyzed foundation and powder samples, while mainly low concentrations were found in eye shadow. These cosmetic products explained approximately 24 % of the measured total Bi amounts reaching the WWTP in 2012, making cosmetics a major Bi source. It is therefore recommended to monitor the Bi concentrations in sewage sludge regularly. Efforts should be made to further examine the sources of Bi to WWTPs and to decrease the emission from Bi in cosmetics to the WWTPs.

#### **The first application of wastewater-based drug epidemiology in five South Korean cities**

K. Kim, Department of Civil and Environmental Engineering; F.Y. Lai, Entox / National Research Centre for Environmental Toxicology Entox; H. Kim, Pusan National University / Civil and Environmental Engineering; P.K. Thai, J. Mueller, Entox / National Research Centre for Environmental Toxicology Entox; J. Oh, Pusan National University / Department of Civil and Environmental Engineering  
Illicit drug consumption in five cities in South Korea was estimated by analyzing 17 drug residues in untreated wastewater samples that were collected during the Christmas and New Year 2012–13 holidays. Only methamphetamine, amphetamine, and codeine were detected at concentrations of tens of nanograms per liter or even lower concentrations in more than 90% of the samples. Other illicit drug residues (including cocaine, methadone, and benzoylecgonine) that have been detected frequently in wastewater from other countries were not found in this study. Methamphetamine was found to be the most widely used illicit drug in South Korea, and the estimated average consumption rate was 22 mg d<sup>-1</sup> (1000 people)<sup>-1</sup>. This rate is, for example, 2–5 times lower than the estimated average consumption rates in Hong Kong and other parts of China and 4–80 times lower than the estimated average consumption rates in cities in Western countries. It should be noted that the wastewater samples analyzed in this study were collected during a vacation, when consumption of illicit drugs are often higher than at other times. The methamphetamine usage rates were calculated for different cities in South Korea, and unexpectedly higher rates (2–4 times higher than the average) were found at the smaller cities. Based on the assumption that the measured concentrations in surveyed period and catchments of this study are representative of South Korea all year round, the available extrapolation suggests an annual consumption of methamphetamine of about 140kg.

155

#### **Contaminants of emerging concern in wastewater discharged into an urbanized watershed in Ontario, Canada**

T. Sultana, Trent University / Environmental and Resource Studies; C.D. Metcalfe, Trent University / Water Quality Centre

Lake Simcoe, north of Toronto, Ontario, Canada has been impacted by a range of human-related activities, including urban development, recreation and agriculture. Discharges from wastewater treatment plants (WWTPs) from several small to medium sized municipalities in the watershed have been identified as sources of phosphorus pollution in the lake. Contaminants of emerging concern (CECs) are also discharged from WWTPs into receiving waters, and for this reason, CECs were identified as a key concern in the Lake Simcoe Protection Plan. The objective of this study was to determine the concentrations of CECs in the effluents discharged from WWTPs in the Lake Simcoe watershed. To achieve this, two passive sampling techniques: the Polar Organic Compounds Integrative Sampler (POCIS) and the Semipermeable Membrane Device (SPMD) designed respectively for monitoring water-soluble (polar or hydrophilic) and water-insoluble (hydrophobic) organic compounds were deployed in six WWTPs in the watershed. The integrative samplers provide estimates of time-weighted average (TWA) concentrations of chemicals over the deployment period of several weeks. Analyses of extracts from the samplers for 14 CEC compounds were performed using liquid chromatography with tandem mass spectrometry (LC-MS/MS) or gas chromatography and mass spectrometry (GC-MS). The estimated TWA concentrations (ng/L) of all target compounds from triplicate analyses were adjusted using *in situ* data on the kinetics loss of Performance Reference Compounds (PRCs) spiked into the passive

samplers. The measured concentrations of the CECs from this study were lower than previously published data on the levels of the target compounds in treated effluents from other Canadian WWTPs. Artificial sweeteners, sucralose and acesulfame are persistent compounds that were present at relatively high concentrations in effluents at all sampling sites. Concentrations of carbamazepine and trimethoprim were estimated to be between 6 to 70 ng/L. Overall, these data indicate that tertiary treatments designed to improve wastewater quality for conventional parameter (e.g. phosphorus) reduce, but do not entirely eliminate CEC inputs in the Lake Simcoe watershed. Keywords (4 max): Wastewater, passive samplers, pharmaceuticals, personal care products

## 156

### **Predicted environmental concentrations of cytostatic drugs in Catalonia (NE Spain), and comparison to measured concentrations in Besòs River**

H. Franquet, Environmental Chemistry; C. Gómez-Canela, F. Ventura, J. Caixach, IDAEA-CSIC; S. Lacorte, IDAEA-CSIC / Environmental Chemistry  
The incidence of cancer in Catalonia has increased considerably in the last years, with 33715 cases registered in 2007. Cancer is treated with cytostatic drugs which can be excreted unchanged or modified as metabolites and be discharged into the sewer system. Besides, elimination of these drugs in waste water treatment plants (WWTPs) is often incomplete [1] and they can finally reach surface waters. The aim of this work was to compile the consumption of all the cytostatic drugs used in Catalonia in the period 2010-2012 in order to calculate the predicted environmental concentrations (PECs). PECs are used to estimate the amounts of drugs expected to be discharged into the environment using publicly available consumption data, excretion values and wastewater elimination rates. Two out of 132 cytostatics had PEC values higher than 10 ng L<sup>-1</sup> (mycophenolic acid and hydroxycarbamide), which is the EMEA threshold for environmental risk assessment [2]. Considering PECs and ecotoxicological data available, the risk quotient was calculated to determine the potential adverse effects of cytostatics in the environment. The results showed no risk for the aquatic environment of Catalonia, although ecotoxicological data is scarce and only individual drugs toxicity is reported in the literature. In a second step, 25 cytostatic drugs, which had the highest PEC values, were analyzed in water samples collected along the Besòs River basin, bordering the city of Barcelona and receiving WWTP discharges of 25 plants. Samples were extracted using Oasis HLB cartridges and eluted with acidified methanol. An LC-HRMS Orbitrap under positive ESI mode and a Luna C18 column were used to perform the analysis. Fifteen drugs were detected, being mycophenolic acid, ifosfamide and chlorambucil the most prevalent compounds. The results obtained were compared with the previously calculated PECs to validate the procedure. Together with *Daphnia magna* EC<sub>50</sub> values, the risk of cytostatic compounds in the aquatic environment was assessed. 1. Heberer, T., *Occurrence, fate, and removal of pharmaceutical residues in the aquatic environment: A review of recent research data*. Toxicology Letters, 2002. **131**(1-2): p. 5-17. 2. ### **Stormwater in Saskatoon -Stormwater in Cryospheric Conditions**

G. Codling, University of Saskatchewan / Toxicology; H. Yuan, University of Saskatchewan - Toxicology Centre; M. Hecker, University of Saskatchewan / School of the Environment and Sustainability and Toxicology Centre; P.D. Jones, University of Saskatchewan / School of Environment and Sustainability; J.P. Giesy, University of Saskatchewan / Toxicology Center  
Precipitation in Saskatoon is dominated by light snow fall (43% of all water), light rain (25%) heavy snowfall (10%) and thunderstorms (10%). Due to the long winter (approx. 6 months) nearly 50% of the annual precipitation enters storm drains over a 2 week melt period and potentially these snows may have accumulated a range of compounds, that are untreated and flow mainly into the South Saskatchewan River. An estimate of volume of water from snowmelt within the city of Saskatoon, based on Canadian Environment agency late winter snowpack depth is some 3.1\*10<sup>9</sup>L of water Since 2011 intensive sampling was done during melt at 7 drain sites covering light industrial, commercial, open land and residential locations within the city limits of Saskatoon, and periodic samples collected between May and October. Samples were tested through toxicology directed chemistry, by which samples were concentrated by SPE and a range of toxic potentials tested, these in turn focused the chemistry. Metal contamination measured in stormwater varies between season with concentrations at many locations for Pb, Cu, U, Ni and other metals exceeding guidelines for storm water. PAHs, and PFCs were measured in a selection of samples based on toxicological responses while LC-Orbitrap in EI and APCI running in full scan +/- was used to identify additional compounds. Keywords: Stormwater, Metals, PAH, Organic contaminants

## 158

### **Mass Balance of Perfluorinated Alkyl Acids in a Pristine Boreal Catchment**

M. Filipovic, Stockholm University / UFZ; U. Berger, Helmholtz centre for environmental research - UFZ / Analytical Chemistry; H. Laudon, Swedish University of Agricultural Sciences (SLU) / Department of Forest Ecology & Management; M.S. McLachlan, Stockholm University / Department of Environmental Science and Analytical Chemistry ACES

To manage the perfluorinated alkyl acid (PFAA) problem, we need to understand the fate and transport of PFAAs in the environment. The chemical and physical

properties of PFAAs vary with chain length, where shorter-chain PFAAs are more water-soluble, while those with longer chains can sorb strongly to soil, which attenuates transport, but also makes them subject to re-mobilization processes. Currently an increasing number of studies have reported on the occurrence of PFAAs in seemingly pristine groundwater and rivers worldwide. However, there are no studies which have evaluated how PFAAs enter surface water from pristine terrestrial ecosystems. The aim of this study was to investigate the transport of PFAAs from atmospheric deposition and snowmelt to river water in a pristine terrestrial environment. The study was conducted within a low population, uniquely instrumented research catchment in Northern Sweden. The work included measuring PFAA concentrations in atmospheric deposition (rain and snow) as well as two rivers from watersheds with varying catchment area and hydrological function. The 14 target PFAAs (9 PFCAs, 4 PFASs and FOSA) were analyzed. Water samples were extracted and cleaned up using solid phase extraction. Qualitative and quantitative analysis was performed using UPLC/MS/MS. A PFAA mass balance of the two catchments was assembled to study the fate of PFAAs. The mass balance calculations show that atmospheric deposition is the most relevant pathway for PFAAs to the remote rivers. Furthermore, the results suggest that both physical-chemical property differences between the PFAAs as well as the water transit time between atmospheric deposition and riverine outflow in combination with emission changes over time alter the PFAA pattern within the catchments.

## **POPs and Pseudo-POPs: Environmental occurrence and exposure (III)**

### 159

#### **A seasonal atmospheric assessment of POPs and pseudo-POPs using passive sampling and modelling**

P. Jimenez-Guerrero, University of Murcia / Physics; S. Ramos, University of Porto / LEPABE/DEQFEUP; J.A. Silva, LEPAE University of Porto; A. Alves, Faculty of Engineering - University of Porto; J.P. Montávez, Department of Physics University of Murcia; N. Ratola, LEPAE- University of Porto / Physics of the Earth  
The atmosphere is a fundamental route of transport for numerous contaminants, so it is very important to measure their levels in the air. And even if some effects are already reported in literature, there are still numerous regions where the information is scarce, like the southeast Iberian Peninsula. With specific climatic fingerprints, it can be an excellent location to assess the atmospheric distribution of contaminants, on a seasonal perspective. Passive air samplers (PAS) have been recently used at regional, continental and global scales and their feasibility was demonstrated in deployments across large areas. Polyurethane foam (PUF) disks were deployed sequentially every three months for a period of one year in 13 sites, comprising four sampling campaigns, one per season. Five chemical classes of pollutants were analysed: three belonging to the persistent organic pollutant (POPs) group - brominated flame retardants (BFRs), polychlorinated biphenyls (PCBs), organochlorine pesticides (OCPs, represented by HCB) – and two other which can be considered pseudo-POPs - polycyclic aromatic hydrocarbons (PAHs) and synthetic fragrances (musk). The main objective of this work was to assess the levels and the spatial and temporal patterns of these pollutants in the Levantine coast (south-east Iberian Peninsula). Atmospheric transport features were also investigated, in correlation with the meteorological data, showing a decisive influence of these parameters. Field data and CTMs were combined to produce a comprehensive overview of a region with a lack of information on these pollutants. Higher levels for PAHs and SMCs were detected in the colder months (autumn/winter) while lower levels were found in the warmer ones (spring/summer). The same was observed for OCPs. In the case of PCBs and BFRs, the predominance was usually found in the spring/summer seasons. Acknowledgements: This work has been partially funded by the European Union 7th Framework Programme-Marie Curie COFUND (FP7/2007-2013) under Programme U-IMPACT Grant Agreement 267143 and by the Operational Programme for Competitiveness Factors - COMPETE and National Funds through FCT (Fundação para a Ciência e a Tecnologia) under the NORTE-07-0124-FEDER-000025. #### **Persistent organic pollutants in background air in central Europe - parameters affecting wet scavenging of polycyclic aromatic hydrocarbons**

P. Shahpoury, Max Planck Institute for Chemistry / Multiphase Chemistry; G. Lammel, Masaryk University; A. Holubová Šmejkalová, Czech Hydrometeorological Institute; J. Klanova, Masaryk University / RECETOX Research Centre for Toxic Compounds in the Environment; P. Pribylova, Masaryk University; M. Váňa, Czech Hydrometeorological Institute  
Concentrations of polycyclic aromatic hydrocarbons (PAHs), polychlorinated biphenyls (PCBs), and chlorinated pesticides (CPs) were measured in air and precipitation at a background site in central Europe.  $\Sigma$  PAH concentrations in air and rainwater ranged from 0.7 to 327.9 ng m<sup>-3</sup> and below analytical method detection limit (< MDL) to 2.1×10<sup>3</sup> ng L<sup>-1</sup>. The concentrations of PCBs and CPs in rainwater were < MDL.  $\Sigma$  PCB and  $\Sigma$  CP concentrations in air ranged from -3, respectively. The potential relationships between PAH wet scavenging and

particulate matter and rainwater properties were investigated. The concentrations of ionic species in particulate matter and rainwater were significantly correlated, highlighting the importance of particle scavenging process. Overall, higher scavenging efficiencies were found for relatively less volatile PAHs, underlining the effect of analyte gas-particle partitioning on scavenging process. The PAH wet scavenging was more effective when the concentrations of ionic species were high. In addition, the elemental and organic carbon contents of the particulate matter were found to influence the PAH scavenging. **Keywords:** gas-particle partitioning, ionic species, elemental carbon, organic carbon

### Passive sampling of PAHs in the petrochemical area of Tarragona County, Spain: PUFs vs. vegetation

N. Domínguez, URVISPV; L. Vilavert, Universitat Rovira i Virgili; M. Schuhmacher, Rovira i Virgili University / Chemical Engineering; J.L. Domingo, Universitat Rovira i Virgili / Laboratory of Toxicology and Environmental Health; M. Nadal, University Rovira i Virgili / Laboratory of Toxicology and Environmental Health

Since 2002, the environmental concentrations of polycyclic aromatic hydrocarbons (PAHs) are periodically assessed in Tarragona County, Spain, where the most important chemical/petrochemical industrial complex in Southern Europe is located. The aim of this study was to determine the levels of 16 PAHs in air and vegetation of different areas of Tarragona County, Spain, as two methods of passive monitoring. Temporal trends of PAH levels in vegetation were estimated by comparing with results from previous surveys. Passive air samplers (PAS) with polyurethane foam (PUF) were used for air monitoring (Newterra, Beamsville, ON, Canada). In June of 2014, 27 vegetation samples were collected in different zones of Tarragona County. In parallel, PUF-PAS were deployed at 16 sampling points in Tarragona County for a period of 2 months. Four samples were collected in each one of the areas under study (petrochemical, chemical, urban/residential, and unpolluted). The average concentration of 16 PAHs in air was 21.4, 29.8, 26.5 and 29.4 ng/m<sup>3</sup> in the petrochemical, chemical, residential/urban and unpolluted areas, respectively. Ranges of the Σ16PAHs concentrations were similar, regardless of the sampling area, with a maximum value of 55.8 ng/m<sup>3</sup> in the industrial zone. Airborne levels were very similar to those previously reported in a number of countries. No significant differences between the study areas were found (p>0.05), likely associated with the sample loss due to the high temperatures in the summer season. The average concentration of 16 PAHs in vegetation was 66.6, 194, 229 and 145 µg/kg in the petrochemical, chemical, residential/urban and unpolluted areas, respectively. A general increase of the levels of 16 PAHs in vegetation can be seen, if compared with data from the first survey, performed in 2002. No significant differences between the study areas were found, with the exception with the raise found in the unpolluted area. Finally, if we compare the PAHs concentrations reported by both monitors, trends are similar in the different sampling areas. The current concentrations of PAHs in samples of ambient air and vegetation of Tarragona are very similar to levels reported in the scientific literature. These results will be used to design a new monitoring network for assessing the occurrence of these pollutants in Tarragona County, an area highly impacted by the petrochemical industry.

## 162

### Long-term environmental monitoring of PCDD/Fs near a municipal solid waste incinerator in Tarragona County (Catalonia, Spain)

L. Vilavert, Universitat Rovira i Virgili; M. Nadal, University Rovira i Virgili / Laboratory of Toxicology and Environmental Health; M. Schuhmacher, Rovira i Virgili University / Chemical Engineering; J.L. Domingo, Universitat Rovira i Virgili / Laboratory of Toxicology and Environmental Health

For approximately 20 years, the concentrations of polychlorinated dibenzo-p-dioxins and dibenzofurans (PCDD/Fs) have been periodically measured in soil and vegetation samples from its surroundings. Since 2006, air samples are also collected by means active and passive sampling devices, and PCDD/F levels are determined [1,2]. The first aim of this study was to determine the current environmental status in the MSWI vicinities by analyzing PCDD/F levels in soil, vegetation and air samples collected between 2013 and 2014. Secondly, the temporal trends of PCDD/Fs were determined by comparing the current data with those from previous surveys. In May/June of 2013, 8 vegetation and 8 air samples were collected around the facility. The sampling sites were the same as those corresponding to the baseline and subsequent surveys. In June of 2014, 8 soil and 8 air samples were collected at the same sampling points. The concentrations of PCDD/Fs in environmental samples were determined by means of high resolutions gas chromatography coupled to high resolution mass spectrometry (HRGC/HRMS). The concentration of PCDD/Fs in eight soil samples varied between 0.16 and 1.61 ng WHO-TEQ/kg dry weight (dw), with an average of 0.63 ng WHO-TEQ/kg (dw). It meant a non-significant decrease comparing to the baseline study (1999) of 47%, and a slight increase to the previous study (2010) of 9% (p< 0.05). The concentration of PCDD/Fs in vegetation, analyzed in 2013, ranged from 0.04 to 0.10 ng WHO-TEQ/kg (dw), with an average of 0.07 ng WHO-TEQ/kg (dw). This means a slight change compared with average values obtained in previous campaigns (1999 and 2009), being the difference not statistically significant. The levels of PCDD/Fs in air, obtained by means passive samplers in 2014, were found between 6.10 and 8.16 fg WHO-TEQ/m<sup>3</sup>, with an

average value of 10.1 fg WHO-TEQ/m<sup>3</sup>. In the last campaign (2010), concentrations were between 6.95 and 3.22 fg WHO-TEQ/m<sup>3</sup>, showing an average level of 10.5 fg WHO-TEQ/m<sup>3</sup>. In the previous study (2013), the total concentrations of PCDD/Fs were collected by active sampling, presented a range of concentrations between 1.88 and 5.29 fg WHO-TEQ/m<sup>3</sup>, with a mean of 3.56 fg WHO-TEQ/m<sup>3</sup>. The above results indicate that the environmental impact of the MSWI of Tarragona is not significant in terms of PCDD/Fs. Furthermore, the environmental levels found in the present study near to MSWI of Tarragona are comparatively low respect to those observed in areas impacted by urban and industrial sources.

## 163

### Air-Water Exchange of Natural Brominated Compounds in the Northern Baltic Sea: New Estimates and Possible Influences of Climate Change

T.F. Bidleman, Umea University / Chemistry; K. Agosta, Umea University; A. Andersson, Umea University / Ecology and Environmental Science; P. Haglund, Department of Chemistry; A. Hegmans, Royal Roads University / Environmental Science; L.M. Jantunen, Environment Canada; O. Nygren, Umea University / Department of Chemistry; J.J. Poole, University of Waterloo / Chemistry; M. Ripszám, M. Tysklind, Umea University / Department of Chemistry

Bromophenols (BPs) are produced by macroalgae and cyanobacteria in the Baltic Sea and oceans worldwide. Compounds derived from BPs include bromoanisoles (BAs), hydroxylated and methoxylated bromodiphenyl ethers (OH-BDEs, MeO-BDEs) and polybrominated dibenzo-p-dioxins (PBDDs). Although natural, these compounds have toxic properties which may be of concern when viewed as part of the mixture with anthropogenic substances. Here we update sea-air exchange fluxes of BAs in the subarctic Gulf of Bothnia, report the first measurements of MeO-BDEs in Baltic water and air, and discuss how climate change may influence production of natural brominated compounds. Water was passed through glass fibre filters (GFF) then through columns of XAD-2 or ENV+ resin to extract BAs and MeO-BDEs. Air samples were collected at the island Holmön (63.79N, 20.84E) on GFF-polyurethane foam traps. Sample extracts were cleaned with Florisil before BA analysis and additionally with 18 M sulphuric acid before MeO-BDE analysis. BAs and MeO-BDEs were determined by capillary GC-MS in electron impact or electron capture negative ion modes. Tetrabrominated MeO-BDEs were confirmed by GC-high resolution mass spectrometry. Henry's law constants (HLCs) for 2,4-DiBA and 2,4,6-TriBA were determined in deionised water from 5–30°C using the bubble stripping method. The most abundant BAs in water were 2,4,6-TriBA and 2,4-DiBA at 64–637 and 20–205 pg L<sup>-1</sup>, while these BAs in air varied from 5.5–116 and 2.1–37 pg m<sup>-3</sup>. 6-MeO-BDE47 and 2'-MeO-BDE68 were found in Baltic water (5–50 and < 3–25 pg L<sup>-1</sup>) and air (11–43 and -3). New gas exchange fluxes of BAs were estimated with the two-film model using temperature-dependent HLCs determined here. Updated 2,4-DBA + 2,4,6-DBA volatilisation from Bothnian Bay (38000 km<sup>2</sup>) between May and September was 650 kg, compared to our previous estimate of 1310 kg. Impacts of climate change on the Baltic Sea include increasing water temperature, greater discharge of fresh water and dissolved organic matter (DOM), and reduction in ice cover and salinity. A shift is anticipated from a phytoplankton to microbial-based food web in the northern Baltic, whereas phytoplankton production in the south is expected to increase under some scenarios of rising temperature and nutrient loadings. These factors may favour or oppose formation of halogenated natural products, but their collective effect is far less clear. A better understanding of their biogeochemistry is required!

### From surroundings to our clothing: Determining uptake rates of fabrics for SVOCs in indoor environment.

A. Saini, University of Toronto / Department of Physical and Environmental Sciences; J.O. Okeme, University of Toronto / Physical and Environmental Sciences; M.L. Diamond, University of Toronto / Department of Earth Sciences

Fabric used in clothing, upholstery, linens and many more applications vary in chemistry as comprised of natural to various synthetic fibres. Clothing can sorb VOCs or SVOCs from the surrounding environment and release them after removal of the source (De Coensel et al., 2008; Feldman, 2010). Chemical sorption by fabric can be a source of human exposure or protection from chemicals in the surrounding environment. Curwin et al (2005) showed that clothing worn by pesticide applicators sorbed the pesticides during their use and hence could prolong the exposure even after pesticide spraying through direct transfer to skin or inhalation of gas-phase pesticides that were released to personal cloud. Horstmann and McLachlan (1994) reported the contaminated T-shirts as source of PCDD/F to human epidermis in wearing trials. The transfer of the compounds from the T-shirt fabric to skin indicated that the chemicals are reversibly sorbed to the fabric. Thus, it stands to reason that SVOCs such as flame retardants and plasticizers, will partition to clothing according to the physical-chemical properties of the SVOCs as well as fabric. The aim of this study was to determine the uptake rates of SVOCs for fabrics and to understand sorption behaviour. Our results reveals that both cotton and rayon show linear uptake of new flame retardants (NFRs) and penta-BDEs for more than a month during deployment period, for instance, uptaking BDE-47 at the rate of 2.8 pg/cm<sup>2</sup> of fabric. Cotton and rayon which is "regenerated" cellulose fabric (Shaikh et al, 2012), showed similar sorptive behaviour. Also, fabric (cotton)-air partitioning coefficients measured for NFRs and BDEs shows good

agreement with their respective octanol-air partition coefficients for those compounds that reached equilibrium. The results confirm that fabrics accumulate SVOCs from their surrounding environment at uptake rates that are consistent with their  $K_{OA}$ . It also indicates that fabrics act as quasi-passive sampler and could potentially contribute to human exposure (protection from or source of) depending on the frequency of laundering.

## Biophysical Interactions at the Bio-nano Interface: Relevance for Aquatic Nanotoxicology

165

### The zebrafish embryo chorion as a biological barrier for nanoparticle uptake?!

S. Böhme, Bioanalytical Ecotoxicology; M. Baccaro, UFZ Helmholtz Centre for Environmental Research / Bioanalytical Ecotoxicology; M. Schmidt, UFZ Helmholtz Centre for Environmental Research / Isotope Biogeochemistry; H. Stärk, UFZ Helmholtz Centre for Environmental Research / Analytical Chemistry; T. Reemtsma, Helmholtz Centre for Environmental Research; D. Kühnel, Helmholtz-Centre for Environmental Research / Bioanalytical Ecotoxicology

The zebrafish (*Danio rerio*) embryo is an established test organism to investigate the toxic potential of chemicals and can be adapted to test nanomaterials by minor adjustments. Compared to chemicals and due to the individual chemical and physical properties of nanomaterials a different and more complex interaction of nanomaterials and the biological components of the zebrafish embryo can be assumed. Especially, the embryo chorion as a possible biological barrier is discussed and was investigated in detail in this study. The investigated silver, gold, and copper nanoparticles were provided and characterised by partners of the EU-project NanoValid. Time kinetic experiments were conducted and the concentration associated to different compartments (the whole egg (embryo with intact chorion), the chorion and the embryo) were determined by acid digestion and ICP-MS measurement of the received homogeneous samples. For all types of particles a time-dependent concentration increase within the chorion and for the whole organism can be observed. The element concentration obtained for the embryos is almost constant over time, independent of the type of particle. In addition, the visualization of the particle distribution by means of LA-ICP-MS was performed on organism sections and particles were located and detected at the chorion surface or within the chorion structures. To prove the function of the zebrafish embryo chorion as a biological particle barrier, we further investigated the chorion surface of exposed organisms by scanning electron microscopy (SEM) coupled with energy-dispersive X-ray spectroscopy (EDX). By these experiments the adsorption of AuNPs and CuO-NPs as single particles and particle agglomerates were identified. Ag was detected, but it was not possible to observe particles or particle agglomerates probably due to the high solubility of this type of particles. Finally, a sorption model based on particle number calculations necessary to saturate the surface and to form particle layers on the chorion was proposed.

166

### Nanosilver cytotoxicity in the topminnow fish (*Poeciliopsis lucida*) hepatoma cell line (PLHC-1) as an *in vitro* toxicology model

A. Bermejo-Nogales, Departamento de Medio Ambiente Lab DETC; M. Fernandez-Cruz, J.M. Navas, INIA - National Institute for Agricultural and Food Research and Technology / Environment

Silver nanoparticles (AgNPs) show a wide spectrum of applications making them one of the manufactured nanomaterials (MNs) with the highest production and, therefore, possibility of release to the environment. Due to antibacterial and antifungal properties these NPs could cause deleterious effects on aquatic organisms, including fish, once they reach water bodies. The use of *in vitro* studies utilizing cultured cells is increasing as a useful tool to observe possible mechanisms of toxic action of MNs and to determine their toxicity while reducing the use of research animals in the context of environmental and health assessment. Diverse mechanisms of cellular toxicity induced by AgNPs have been described such as loss of viability, lysosomal damage, increased oxidative stress, mitochondrial injury and DNA damage that can differ according to cellular type and exposure conditions. The aim of the present study is to determine the cytotoxic effects and cellular interaction of AgNP obtained from the JRC Repository (AgNM300K) and AgNO<sub>3</sub> (as Ag<sup>+</sup> ion source) in the topminnow fish (*Poeciliopsis lucida*) hepatoma cell line (PLHC-1) as an *in vitro* toxicology model. Cytotoxicity was evaluated with classical toxicity assays performed on the same set of cells with fluorescent dyes (AlamarBlue, CFDA-AM and neutral red). The induction of oxidative stress was assessed by measuring intracellular reactive oxygen species (ROS) levels. Interaction with cellular structures was investigated by transmission electron microscopy (TEM). The results show that AgNM300K dispersions have a stable distribution, circular aspect and a size of  $16.04 \pm 0.32$  nm diameter that can be enlarged due to formation of a protein corona. PLHC-1 cells are more sensitive to Ag<sup>+</sup> ions at low concentrations but as concentration rises the AgNM300K toxicity also increases. TEM images show that toxic concentrations induce mitochondria swelling and AgNP presence in vacuoles. However, at non-toxic concentrations AgNPs appear as clusters inside nucleus, mitochondria, vacuoles and cytosol. PLHC-1 cells cytotoxic effects produced by AgNM300K after 24h exposure are related to vacuolization process and metabolic disruption and it opens the question

of possible genotoxic mechanisms in the absence of ROS production. PLHC-1 cells are a good model for ecotoxicology studies of AgNP to be used in the framework of intelligent testing strategies. *Acknowledgements* - This research was supported by FP7-MARINA project (Grant Agreement No. 263215).

### Toxic effect of pristine SWCNT combined with Cadmium to the crustacean *Daphnia magna*

M. Revel, INRS-Institut Armand-Frappier; M. Fournier, Institut Armand Frappier-INRS / Immunotoxicology Laboratory; P. Robidoux, Université de Sherbrooke / Aquatic and Crop Resource Development Portfolio

Production increase of carbon nanomaterials and development applications raises the question of the consequences of their release on wildlife, including pelagic species which may be exposed. In Canada, the forestry industry experienced an economic crisis which has led to the elaboration of new forestry products like nanomaterials, including single-walled carbon nanotubes (SWCNT). SWCNT offers many benefits because of their high electrical and thermal conductivity and also mechanical properties such as toughness and strength. On top of that, they possess a very large surface area allowing them to adsorb hydrocarbons or metals present in water or soil. Consequently, they are closely studied for environmental monitoring and wastewater treatment. Nowadays, it's important to study the potential interactions between carbon nanomaterials and environmental contaminants. This study focuses on the toxicity of single-walled carbon nanotubes (SWCNT) in presence of cadmium (Cd), using the crustacean *Daphnia magna* and 48-h lethality tests. The LC50 for Cd or pristine SWCNT, as well as their mixture were estimated and compared. We found that SWCNT were able to adsorb Cd and that the presence of SWCNT increases the toxicity of Cd to *D. magna*. LC50 for Cd and SWCNT were 252.3 and 1400 µg/L, respectively. In the presence of a fixed concentration of SWCNT, LC50 of Cd decreased. The lowest LC50 of Cd was 111.1 µg/L in presence of 1000 µg/L of SWCNT, indicating an increase in Cd toxicity. SWCNT accumulation in the digestive tract of *D. magna* was confirmed with binocular microscope observations. The increase in toxicity may be due to the adsorption of Cd on the carbon nanotubes which induces a higher entrance of Cd in the digestive tract of *D. magna*. Then, once entered into the digestive tract, Cd will be desorbed helped by the enzymatic conditions contributing to desorption processes. Those results show the complexity of SWCNT toxicity and how the understanding of their interactions with other contaminants is crucial to determine the consequences of their release in the environment.

168

### The effect of colloidal stability and Ce valence states at the surface of cerium oxide nanoparticles on cellular toxicity

G.P. Reyes, Biology department; I. Rodea-Palomares, F. Leganes, Universidad Autónoma de Madrid / Biology; S. Das, S. Seal, University of Central Florida; R. Rosal, Ingeniería Química; F. Fernandez-Piñas, Universidad Autónoma de Madrid / Biology

Cerium oxide nanoparticles (CNPs) have been used in numerous engineering and biological applications: in plants to increase photosynthesis<sup>1</sup>; also as an antioxidant by using the protective effects of nanoceria in certain neurological and cardiological disorders<sup>2</sup>; seems to provide cells protection from radiation. However, CNPs have also been found to display oxidase activities and to generate damaging oxygen radicals in a range of organisms and cell systems<sup>3</sup>. We have performed a thorough study of the effect of seven different CNPs on a model aquatic microorganism, the green alga *Pseudokirchneriella subcapitata*, in an effort to untangle the mechanisms which underlie the biological activity of CNPs. In order to study the effect of Ce<sup>3+</sup> valence states on the surface, the tested CNPs have a defined surface percentage of Ce<sup>3+</sup>; show distinct morphologies (round, rods or cubes) and two of them are dextran-coated. Among all these factors, we found a good positive correlation between the surface percentage of Ce<sup>3+</sup> and toxicity (related with an increase in intracellular oxidative stress). Furthermore, we have modified the colloidal stability and redox chemistry of the CNPs with citrate, iron and phosphate buffer. We found that colloidal stability did not modulate the cellular toxicity of non-toxic CNPs (citrate and Fe treatments). However, the toxicity of 'toxic' CNP increased by colloidal destabilization (Fe treatment). Finally, by blocking the redox cycling between Ce<sup>3+</sup> and Ce<sup>4+</sup> of Ce<sup>3+</sup> enriched CNP in the surface (phosphate buffer treatment), toxicity and oxidative stress was totally prevented. Thus, our results suggest a strong relationship between percentage of Ce<sup>3+</sup> on the particle's surface and toxicity. **References** [1] Giraldo J, Landry M, Faltermeier S, McNicholas T, Iverson N, Boghossian A, *et al.* 2014. ### Toxicity and dietary transfer of silver nanoparticles

J. Kalman, School of Life Sciences; K.B. Paul, Heriot-Watt University / SLS; F.R. Khan, Roskilde University / ENSPAC; V. Stone, Heriot Watt University; T.F. Fernandes, Heriot-Watt University / School of Life Sciences

The objectives of this study were to investigate the toxicity and dietary transfer of AgNO<sub>3</sub> and Ag NPs with different coatings (PVP, PEG and Citrate) using two freshwater organisms, the green alga, *Chlorella vulgaris* and the crustacean, *Daphnia magna*. The inhibitory effect of AgNO<sub>3</sub> (IC50 of  $5.3 \pm 0.5 \mu\text{g L}^{-1}$ ) to *C. vulgaris* was significantly higher than the Ag NPs. Citrate-, and PVP-coated Ag NPs exhibited similar toxicity (IC50 values of  $9.2 \pm 1.0$  and  $9.3 \pm 0.1 \mu\text{g L}^{-1}$ , respectively), while PEG-Ag NP was significantly less toxic to the algae (IC50 of  $49.3 \pm 5.2 \mu\text{g L}^{-1}$ ). Uptake rate constant ( $K_u$ ) and membrane transport characteristics ( $B_{\text{max}}$ ,  $K_d$  and  $\text{Log } K$ ) were determined after exposing algae to ranges of concentrations of AgNO<sub>3</sub> or Ag NPs. The  $K_u$  and  $\text{Log } K$  correlated well with the toxicity in the algae. Transmission Electron Microscopy was used to observe possible internalization of Ag NPs in algal cells after exposure to low concentrations for 72 h (mimicking inhibition tests) or to high concentrations for 4 h (mimicking dietary exposure). Ag NPs were visualized only in algal cells used in the dietary exposure, probably due to the increased membrane permeability of *C. vulgaris*. To establish biodynamic model parameters (i.e. assimilation efficiency and efflux rate constant), *D. magna* were fed Ag-contaminated algae and depurated for 96 h. The two compartmental loss of Ag showed that *D. magna* assimilated significantly less Ag from AgNO<sub>3</sub>-exposed algae (8 %) than from the Ag NP - exposed diet (14 - 16 %). However, PVP-, and PEG-coated Ag NPs were more difficult to eliminate by the daphnids. Biodynamic model prediction revealed that food is the dominant pathway of Ag uptake in *D. magna*, except for AgNO<sub>3</sub> when applying the low Ag concentration in food. Model-predicted steady-state Ag concentrations in *D. magna* are unlikely to cause adverse effect. Given that daphnids did not eliminate completely Ag NPs, there is a possible transfer of Ag NPs along the food chain.

## Advancements in life cycle impact assessment and footprint method development (III)

170

### Human health impact assessment model considering trade-induced effects arisen from agricultural water scarcity

M. MOTOSHITA, National Institute of Advanced Industrial Sci. and; Y. Ono; S. Pfister, ETH Zurich; A. Boulay, CIRAG - École Polytechnique de Montréal / Chemical engineering department; M. Berger, Technische Universität Berlin / Chair of Sustainable Engineering Office Z; K. Nansai, Nat. Inst. of Env. Studies (NIES); K. Tahara, National Institute of Advanced Industrial Science and Technology / Research Institute of Science for Safety and Sustainability; N. Itsubo, Tokyo City University; A. INABA, Kogakuin University; M. Finkbeiner, DaimlerChrysler AG / Chair of Sustainable Engineering

Assessing the potential impacts of water use has become one of the great concerns in life cycle assessment. Especially, demand for agricultural use dominates a large part of total water demand for human society and will be significantly affected by water consumption. Agricultural water scarcity will potentially result in the shortage of food supply and human health damage as a consequence of the increasing rate of undernourished population. Regarding vulnerability to food supply shortage, the amounts of food stock will control the resilience of a population. In addition, international food trade links food exporter and importer countries and will consequently expand countries affected by the food shortage through price changes in the global market, even if water consumption is occurring in another country. In order to account for these effects, we integrated food stocks and trade-induced effects into the characterisation model on human health damage due to agricultural water scarcity. The characterisation model composed of three assessment modules (1) food production loss assessment, 2) food supply shortage assessment and 3) health damage assessment) was developed to model the impact pathway from freshwater consumption to human health damage through agricultural water scarcity. Characterisation factors (CFs) at the country scale widely range from  $7.13 \times 10^{-9}$  to  $6.15 \times 10^{-5}$  [DALY/m<sup>3</sup>]. Even though developed countries also show high CFs, most of their health damage is caused in more vulnerable countries due to the compensation of food shortage through international food trade. According to the current water consumption pattern, large amounts of water are consumed in India (14%), China (12%), USA (10%), Brazil (4%), Russia (4%). However, malnutrition damage attributed to water consumption in those countries is occurring in vulnerable countries: Yemen (9%), Philippines (6%), Angola (4%), Nigeria (4%), Mali (4%). This indicates that water consumption in a country can be responsible for health damage in other vulnerable countries. From the viewpoint of agricultural water scarcity, this characterisation model revealed that the risks of health damage in other countries are of significance in the context of water footprint.

171

### Increasing the ecological relevancy of volumetric grey water footprints

P. Van Sprang, ARCHE

One of the most prominent volumetric methods to account for water footprinting has been developed by Hoekstra et al. (2011). One of the pillar relates to the grey water footprint for point sources which is an indicator of the degree of freshwater

pollution that can be associated with the discharge of pollutants in receiving surface waters. It is defined as the volume of freshwater that is required to assimilate the load of pollutants from point sources based on natural background concentrations and existing ambient water quality criteria (WQC). However, often criticism has been formulated that turning a water quality measure into a water quantity measure loses information about the potential impact that pollutants may cause in the receiving environment. This study aims at improving the ecological relevancy of the current volumetric methodology for the calculation of the grey water footprint of point sources by introducing risk assessment concepts as used within REACH or the Water Framework Directive. In first instance we advocate to use relatively simple accepted concepts such as the solid-water partitioning or rapid degradation of pollutants to increase the realism of the grey water footprint. Additional refinement of the methodology could be achieved by correcting the generic existing ambient WQC of metals for bioavailability in order to estimate more relevant and robust river-specific WQC for such pollutants. Furthermore, the current WFN methodology only considers the critical load in the overlying water therefore neglecting potential more sensitive ecological (e.g. top predators) and human (through fish consumption or drinking water). Examples of the introduction of such refinements on the grey water footprints for discharged pollutants Pb (metal) and metazachlor (herbicide) will be presented.

172

### A methodology and model for characterizing regional and temporal impacts of power plant thermal emissions on rivers

J. Boucher; S. Pfister, ETH Zurich; J. Bayart, Quantis International; D. Corbisier, Laborlec; E. Favrot, GDF SUEZ; M. Vargas-Gonzalez, Quantis International; A. Prieur-Vernat, GDF SUEZ DRT-CRIGEN

The use of once through cooling systems in power generation is globally widespread. These systems intake river water at its current temperature, use it to extract excess generated heat from the power plant, and then return it to the river in a heated form. This excess thermal energy raises the temperature of the river water downstream, causing a number of negative impacts. While much is known about the types of impacts these cooling systems have, less has been developed in terms of being able to model and quantify impacts specific to a site's environmental conditions. This study quantified the impact of the added thermal stress on river ecosystems by developing a methodology and a modeling tool to calculate characterization factors (CFs) that take into account regional differences such as the climate and temporal influences such as seasonal changes in water temperature and the operating level of the power plant. The developed method calculates the fate of emitted heat from a cooling system, the effect and impact this heat has on species within a river, and scales the result based on existing, local background heat stress to account for resilience. While many of the needed inputs can be entered into the model manually, a global database was created so that missing variables can be estimated for any site based on its geographic coordinates. As a case study, four locations (one in Canada, Germany, India, and China) each in a different climate zone were modelled using constant heat emission parameters. Results show that impacts on sites located further from the equator are concentrated much more heavily in the warmer, summer months. This includes a peak to minimum monthly impact ratio of ~5'000 in the northern, boreal climate of Canada versus a ratio of just 2 at the location in the tropical climate of India. The yearly average impact of the selected sites varies by less than a factor of 3. The developed methodology and tool enlarge the operational scope of water use impacts, and the results highlight the importance and feasibility of considering temporal as well as regional influences in calculating such characterization factors. Adjusting power plant operation in time to minimize impacts caused by cooling systems requires site-specific investigation, and the developed modelling approach can assist in this regard.

173

### Assessing the potential damages of eroded solids on aquatic ecosystems: case study on Eucalyptus globulus forest

p.S. quinteiro, University of Aveiro / CESAM Department of Environment; M. Van de Broek, Katholieke Universiteit Leuven / Division of Geography; A.C. Dias, University of Aveiro / CESAM Department of Environment; b. ridoutt, CSIRO; L. Arroja, University of Aveiro

High concentrations of sediments reaching lotic environments and remaining in suspension can be a significant stressors to the biodiversity of these aquatic systems. This damage is presently not considered in Life Cycle Assessment studies. This study is devoted to the effects of sediments into freshwater systems due to soil erosion by water (environmental mechanism), translated into damage to aquatic ecosystem diversity (endpoint impact category), namely to macroinvertebrates and algae/macrophytes. For this, we have developed a framework to conduct an erosion inventory using the WaTEM/SEDEM model and linked this with, a method to derive regional characterisation for endpoint damage on aquatic ecosystem diversity. A case study was performed for *Eucalyptus globulus* stands in Portugal, with a functional unit of one hectare of land under production forestry management. To demonstrate how this newly suspended sediments (SS) ecosystem method can help to improve the environmental assessment in forestry, results were compared with the earlier commonly used impact categories from ReCiPe method. The resulting damage on freshwater ecosystem due to the increased SS in the water column for the *E. globulus* stands studied ranged from  $1.3 \times 10^{-7}$  to  $9.7 \times 10^{-6}$  species.yr.ha<sup>-1</sup>.revolution<sup>-1</sup> for macroinvertebrates, and from  $4.1 \times 10^{-8}$  to  $3.3 \times 10^{-6}$

species.yr.ha<sup>-1</sup>.revolution<sup>-1</sup> for algae/macrophytes. Both impacts were calculated after weighting the endpoint regional characterisation factors units in potentially disappeared fraction (PDF) In m<sup>3</sup>.yr.kg<sup>-1</sup> of SS, considering recommended freshwater species density (7.89×10<sup>-10</sup> species.m<sup>-3</sup>) and total number of described freshwater species (100,000 species). The results show that for macroinvertebrates, the SS damage values are (1) between 2 and 3 orders of magnitude higher than the values for freshwater eutrophication, (2) were of same order of magnitude or 1 order of magnitude higher than the values for both freshwater ecotoxicity and terrestrial acidification, and (3) were lower than the values for ecosystem climate change. All of these impact categories are estimated using ReCiPe. Similar trends have been achieved for algae/macrophytes. The results allow us to conclude that the increase of SS in water column can cause biodiversity damage and that the calculated values are higher than the ones obtained for impact categories of the commonly used ReCiPe methodology.

## LCA of complex systems: delusion or reality? (II)

175

### Guiding development of interconnected bioenergy and bioproduct systems with life-cycle energy, water, land, and greenhouse gas metrics

C.D. Scown, Lawrence Berkeley National Laboratory / Environmental Energy Technologies Division; A. Horvath; T.E. McKone, University of California / School of Public Health

Bioenergy is likely to be an important component of many countries' future renewable energy portfolios. Liquid biofuels are particularly critical to providing near-term carbon mitigation without relying on the slow turnover of fleet vehicles and construction of new infrastructure. However, bioenergy production systems exist at the intersection of biology, ecology, chemistry, engineering, and policy, which makes optimizing these systems a complex and interdisciplinary challenge. We present the results of a long-term research effort aimed at quantifying the carbon, energy, water, and economic tradeoffs of advanced biofuel production strategies. First, we examine the challenge of producing ethanol from cellulosic feedstocks in the United States, including *Miscanthus x giganteus*, corn stover, and wheat straw. A 40 billion l/year scenario shows that the land footprint of dedicated crops can be minimized by selecting land with the largest fuel yield/ha difference between the incumbent feedstock (corn) and *Miscanthus*, totaling 7.5 million ha. Eliminating drought-prone counties and constraining conversion to regions with the largest carbon offset credit for exported power increases total land requirements to 8.8 million ha; in both cases, short-term net carbon sequestration could reach 25 gCO<sub>2</sub>e/MJ due to power offset credits and soil carbon sequestration. Adding corn stover and wheat straw that can be sustainably harvested and economically transported to commercial-scale biorefineries allows total cellulosic ethanol production to reach 60 billion l/year. Because the modeled biorefinery locations are aligned with U.S. coal-fired power plants, we show that biorefinery capital costs can be substantially reduced, life-cycle water impacts can be reduced, and greenhouse gas (GHG) emissions can be held constant by exporting lignin for pelletization and co-firing at coal power plants; even with expected coal plant retirements, there will be sufficient capacity to accept 100% of potential lignin production through 2050. However, our transportation energy demand scenarios show that, even in the case of modest passenger vehicle electrification, 60 billion liters/year of ethanol will approach the flex-fuel blending limit for all remaining gasoline consumption. Thus, we explore sugarcane-derived drop-in biofuel pathways and show that optimized pathways have the potential to reduce GHG emissions relative to fossil fuels by nearly 90%.

176

### Does resilient mean eco-inefficient?

M. Pizzol, Aalborg University / Development and Planning

Resilience is a property of systems that is deemed essential for their sustainability. The term "resilience" has become a vague buzzword in the last few years but the literature agrees that resilience depends on the structure and architecture of a system. It increases with system complexity, because the redundant connections between elements of a system make it less efficient but also more flexible and adaptable and allow to perform a function even if some connections are interrupted or missing. Balancing between resilience and efficiency seems to be the key for sustainability intended as long-term performance. Resilience is not explicitly taken into account within life cycle assessment (LCA). LCA determines the eco-efficiency of product systems, i.e. the ratio between the function provided by the product and its impact on the environment. The question is whether a product system which structure is improved or designed to be more resilient will not only be more inefficient, but also eco-inefficient, when studied by means of LCA. In this work a two steps approach is proposed to study resilience of product systems: 1) assessment of disturbance conditions and their inclusion within the scope of the LCA study; 2), system expansion, i.e. changing the structure of the system by including additional disturbance-preventing processes and disturbance-dependent

ones. This theoretical LCA modelling approach was tested on two fictional case studies using data from literature: A) the example of two different waste management systems of a remote island disturbed by stormy weather; B) the example of two different biofuel systems, single- and multiple-feedstock, disturbed by climate changes. Results shows that if proper LCA modelling is applied, resilient product systems are not necessarily less eco-efficient than their vulnerable counterparts and instead can allow for eco-efficiency gains. This goes against the intuitive idea that optimizing a system for efficiency only will necessarily allow achieving eco-efficiency as well, and suggests that design for resilience may be a valuable idea towards sustainability. However, further experimental work on the subject is needed to draw more robust and generalizable conclusions.

177

### Implementation of recycling systems: The delusive role of LCA

T. Kägi, F. Dinkel, Carbotech AG

Shall materials with heating values, from a demand point of view, be materially recycled or rather thermally utilised in order to get the highest benefit? This and similar questions are often raised by governments and politics. We realised that the results strongly depend on the recycling allocation approach. Furthermore, the benefit of incineration increases when the proportion of fossil fuel in the energy mix it replaces is higher. In some cases this benefit can be high enough for thermal utilisation to seem to be, from an environmental perspective, a better option than material recycling. In other words: in countries with poor energy strategies, recycling of materials with heating values would be less advisable. On the other hand, material recycling is highly profitable in case a region only uses renewable energies. Hence, from an environmental perspective, the failures of energy policies in most countries hinder further developments in recycling of materials with energy values. LCA is still considered to be the best method to quantify and therefore compare the impact on the environment. Consequential LCA is widely considered as a suitable policy support because of its ability to model consequences to some extent. But when addressing the role of LCA in the implementation of circular economy and its role as a policy support the question arises whether or not the consequences we model lead to constructive results. In case the consequence for a region is to quit recycling materials because of an (environmentally) inappropriate energy mix, a development of recycling technologies will be stopped that could actually be preferred in the future. It is not the recycling that is not environmentally favourable, it is the energy strategy hence the energy mix of a country. Yet recycling is blamed for not being the best environmental option. This means that we chose options that will lead to disadvantages in the future. Even though LCA grasps the environmental aspects quite well, the problem clearly lies in asking the right questions rather than mixing up different aspects of the same problem. Even if the results seem clear at first sight, great attention needs to be paid to the right communication with policy makers so that they not only understand the results but also the true underlying reason of the consequences of implementing measures induced by LCA results.

178

### Multicriteria optimization of a biorefinery for the production of bio based flame retardant and other bio products

O. Mrani, TECHNISCHE UNIVERSITÄT DARMSTADT / BauIng; L. Schebek, Technische Universität Darmstadt / Material Flow Management and Resource Economy

The project PHOENIX, which is funded by the European Union (EU), aims at the development of non-halogenated flame retardants based on biogenic resources. The research investigation covers the entire spectrum from developing materials to their industrial application. As part of the project, LCA is carried out for decision support to all stakeholders involved in the development process. In order to deliver support strategies for decision processes, LCA has taken into account that a biorefinery system is composed from several production lines, multiple biomass resources and multiproducts. To tackle this complexity, optimization methods can be used in order to speed the analysis of the multitude of variant under consideration during technology development. We selected the optimization method analytic hierarchy process (AHP) knowing that AHP has, not only, been frequently applied in MCDA, but it also provides userfriendly support to decision making group by simplification and rationalization of complex decisions. A biorefinery system is commonly divided into three levels, which in turn are divided into subcategories. The first top level includes the entire biorefinery (top management level, management of the entire biorefinery and overall chemical production-platform). The second level represents the production lines, which correspond to the desired end products of the biorefinery (management of the production line, for example production of bioethanol etc.). These production lines are generated from successive process chains which are on the third level (line of individual process for example cultivation of biomass, transport etc. Each process chain again contains several alternatives with multiple indicators which are optimized as to finding and designing the final biorefinery. In the proposed biorefinery framework, the weighting of the criteria and interests changes depending on the hierarchical level. This means that one criteria may be relevant as to one specific level and at the same time insignificant for the other levels. The optimization result factors in the interests of all three levels (overall management, production management and processing).

179

#### **Environomic multi-objective optimization of an eco-industrial park**

L. Lessard, Quantis; P. Collet, IDEEL; M. Kermani, F. Maréchal, École Polytechnique Fédérale de Lausanne

A circular economy refers to an industrial economy with a cradle to cradle vision, shifting from the use of fossil fuels towards renewable energy, minimizing the use of toxic chemicals and reducing waste by recycling through careful system design. The concept of a circular economy is based on the study of non-linear, in particular living systems, with a major outcome being the optimisation of systems rather than of the individual components which make up each system. Industrial symbiosis (IS) is the exchange of energy, waste and by-products among industries in order to add value, while reducing costs and environmental impacts. This is consistent with the principles of a circular economy, and is a stepping stone towards the design of sustainable economies and policies. In the scope of this study, the use of local and renewable resources and the development of industrial ecology can contribute to the decrease of environmental impacts of a living, interactive system, on a given territory. A process system design framework is developed to model a superstructure that contains the list of possible options for the system. The LCA is used to calculate the environmental impacts of a product or a service. The method requires certain adjustments in order to assess the impacts of a spatially delimited system. The design of such system can be done by combining Life Cycle Assessment (LCA) that can provide a clear and structured framework to assess the environmental impacts of the system and process system design methods that applies mathematical programming techniques to systematically design territorial configurations using costs and thermo-chemical or physical models. The new method allows to generate the most attractive scenarios for the systems using a systematic modeling framework and using an optimisation approach that allows to generate a limited set of pareto optimal configurations that can then be evaluated to identify the most attractive solution. The method has been successfully applied on a case study of a city with 100,000 inhabitants.

##### **Environmental benefits of industrial symbiosis for the steel industry:**

##### **Application of stainless steel slag**

A. Di Maria, KU Leuven / MTM; M. Salman, M. Dubois, K. Van Acker, KU Leuven

The steel industry is a key sector in the implementation of the Industrial Symbiosis (IS). Despite a wide literature on strategies for IS in steel industry, research should focus on the valorisation of those residues whose potential for recycling is not explored at present. The current study presents an environmental evaluation of a novel process aiming at the recycling of Stainless Steel Slag (SSS) as a binder for the production of construction materials. Currently, SSS is stabilized with borates addition and recycled as low-quality aggregate. SSS poses environmental threats due to the chromium content. Moreover the dusty texture makes the handling difficult. Therefore research for more sustainable solutions is needed. Thermo Alkali-Activation (AA) process can be applied to SSS to produce a new binder for construction materials. The process activates the binding property of SSS through the addition of alkali silicate in a high temperature environment, hence foregoing the need of stabilization by borates. For the presented study, two different blocks (S-Blocks) were developed through AA using SSS slag as binder: **1) Solid S-Block**- similar to traditional paver concrete block and **2) Aerated S-Block**- with a porous internal structure similar to traditional aerated block. A Life Cycle Assessment (LCA) using a “cradle to gate” approach has been conducted in order to assess the environmental impacts of three different scenarios: **Scenario 1 (no valorisation)**- SSS is stabilized through boron addition and sold in the market as low-quality aggregate, **Scenario 2 (Solid S-Blocks valorisation)** – SSS is valorised through production of 1m<sup>2</sup> of Solid S-Blocks and **Scenario 3 (Aerated S-Blocks valorisation)**- SSS is valorised through production of 1m<sup>2</sup> Aerated S-Blocks. Scenarios 2 and 3 have been further compared with LCA on production of 1 m<sup>2</sup> traditional blocks with similar properties that are already available in the markets. The LCA results show that the two valorisation scenarios have similar (scenario 2) or higher (scenario 3) impacts compared with scenario 1. However, the production of S-blocks has lower impacts comparing to production of their substitutes in the market. The environmental analysis indicates the advantages of industrial symbiosis in stainless steel production industry. LCA acted as a powerful tool to assess the environmental performances of new waste valorisation practices and the impacts of the application of IS.

#### **Ecological Risk Assessment and Sustainable Management of Contaminated Sediment: Perspectives and Experiences**

#### **181**

##### **A selection of sediment quality benchmarks for ecological risk assessment: contamination of DDT and Hg in Lake Maggiore (Italy)**

L. Marziali, IRSA-CNR (Brugherio); L. Guzzella, Italian National Research Council Water Research Institute CNIRISA; D. Rabuffetti, Regional Agency for the Protection of the Environment of Piedmont / Department of Verbano Cusio Ossola

Lake Maggiore in Northern Italy is characterized by residual DDT and mercury contamination of sediments caused by the activities of a factory located nearby of the Toce River, one of the main tributaries of the lake. An environmental risk

assessment (ERA) analysis is necessary to assess the potential risk for the aquatic ecosystem. For what concerns exposure, contaminated sediments were proved to be the main exposure pathway for the aquatic fauna. Therefore one of the focal point of the ERA was the study of the site-specific bioavailability of DDT and Hg.

Bioavailability was assessed using different approaches: 1) analysing bioaccumulation in benthic invertebrates belonging to different taxonomic/functional groups; 2) deploying passive samplers like PE (Polyethylene membrane) loaded with PRC (Performance Reference Compounds, i.e. labelled-DDx compounds), and Diffusive Gradients in Thin Films Spheron-Thiol+agarose passive samplers (DGT). For what concerns sediment quality benchmarks, the selection of proper thresholds was challenging, being intended to predict different levels of risk associated with sediment toxicity. At first, a comparison with existing international sediment quality guidelines allowed to identify screening levels considered safe (i.e. no effect) for the ecosystem. In case of higher contaminant concentrations, as in the case of the Toce River and the Pallanza Bay in the lake, further benchmarks (e.g. probable risk, moderate level effect, severe level effect) were selected. At this purpose, a review of standard toxicity tests and SSD calculations for benthic invertebrates from the scientific literature and from existing toxicity databases was carried out. Similarly, published papers relating body burdens and toxic effects for invertebrates were analysed. Values of acute and chronic NOEC, LOEC, LC<sub>50</sub>, EC<sub>50</sub>, HC<sub>5%</sub>, HC<sub>50%</sub> were selected for defining different risk levels. The selection of proper benchmarks for the ecological risk assessment poses strong implications for environmental management, leading decision for remediation measures.

#### **182**

##### **Bioavailability and toxicity of sediment-bound contaminants (PCBs and metals) using an integrative approach: a case study in the Venoge river (Switzerland).**

L. Molano Leno, Eawag, Aquatic Research; M. Casado-Martinez, Centre Ecotox; N. Estoppey, University of Lausanne; F. de Alencastro, EPFL Swiss Federal Institute of Technology in Lausanne; I. Werner, Swiss Centre for Applied Ecotoxicology / Department of Anatomy Physiology and Cell Biology; B. Ferrari, Ecotox Centre CH

The Venoge is a small river flowing into Lake Geneva, the largest water body of Switzerland. Previous monitoring campaigns have shown increased concentrations of PCBs in fishes, which were reported to exceed maximum levels set by the European Union for human consumption. Water quality of the river is well characterized, both in terms of chemical contamination and benthic macroinvertebrate community structure. However, no information of sediment quality is available so far. To assess the potential impact of sediment bound contaminants on habitat quality, we used an integrated methodology that includes sediment physico-chemical measurements, a battery of sediment toxicity tests, and measurement of contaminants in benthic invertebrates. Sediments were collected at several sampling sites along the Venoge and analyzed for PCBs and metals as well as ancillary parameters important for determining contaminant bioavailability. The battery of tests used for the characterization of sediment ecotoxicity included the growth inhibition test using the aquatic macrophyte *Myriophyllum aquaticum* (ISO 16191); the growth and mortality test using the ostracod *Heterocypris incongruens* (ISO 14371); and the emergence test using midge larvae (*Chironomus riparius*, AFNOR 90-339). Bioaccumulated contaminants were assessed in midge larvae. Four sampling sites were selected according to the identified sources of contamination and previous results of water quality. Results of the toxicity tests showed no effect on ostracod mortality but growth inhibition at the sampling site closest to the mouth of the river. On the contrary, percent emergence of midge larvae was decreased only at the site closest to the effluent outfall of the waste water treatment plant. Chemical analyses of sediments and midge larvae are on-going. The results will be discussed based on the two objectives of this study: 1) to assess whether sediments are contributing to the impairment of the beneficial uses of this aquatic ecosystem (ecosystem services) and 2) to assess which of the selected tools can provide useful information within a decision-making framework.

#### **183**

##### **Regional Sediment Quality Guidelines within the European Water Framework Directive: strengths, weaknesses, opportunities and threats. The Basque coast as case study**

I. Menchaca, Marine Environment Department; J. Rodríguez, . Borja, J. Franco, Azti-Tecnalia; J. Garmendia, AZTI Foundation; J. Larreta, M. Belzunce, Azti-Tecnalia

The regional SQG values developed in the present study, using four different organisational biological levels, are proposed to be used as guidance values for project managers and decision makers, in assessing chemical and physicochemical status in marine waters, to be used within the European Water Framework Directive. The aims of this study are (i) to calculate the regional SQG for metals and organic compounds (PCBs and PAHs) for the Basque coast (Bay of Biscay), based upon the chemical, toxicity and benthic biotic index values, (ii) to compare these regional SQG values with international values and, (iii) to carry out SWOT analysis

#### **184**

##### **Contaminated sediments in backwaters of the Elbe - do they pose a risk to the river's quality?**

S. Heise, Hamburg University of Applied Sciences / Life Sciences; U. Rieth, Institut für Hygiene und Umwelt

The German Elbe river flood plain has more than 1000 individual backwaters covering an area of altogether 50 km<sup>2</sup>. In the context of setting up a concept for a basin-wide sediment management by the International Commission for the Protection of the Elbe (IKSE), this study was initiated in order to inform the IKSE on the relevance of backwater sediments for the quality of the Elbe. At that moment, very little was known about the contamination of those sediments and to what extent they were exchanged with the major river. In 2013 and 2014, 25 backwaters were investigated with regard to sediment contamination, ecotoxicity, erosion stability, and thickness of the potentially resuspendable sediment layer. Dating of selected cores was done by measuring activity of <sup>137</sup>Cs and by determination of heavy metal profiles over the sediment depth (still ongoing). When compared to the nationally defined Environmental Quality Standards (EQS) for contaminants in sediments, all sediments exceeded the Ni criterion, 75 % of sediment samples exceeded the EQS with regard to As, Pb, Cd and Hg concentrations. More than 50 % of sediment samples showed concentrations for HCH, DDX, HCB and some PAHs (e.g. fluoroanthene) that were above the respective quality criteria. Ecotoxicity in these samples ranged from very low to very high and did not necessarily reflect the results from the chemical analysis. There is a first indication, that bioavailability of hazardous compounds was higher in those samples that had not undergone frequent resuspension/deposition cycles. Better understanding of sediment dynamics in these backwaters therefore is crucial – first of all because of the transport of contaminated material into the river and second (if our observations can be supported by further analysis of these data) with regard to the potential consequences for bioavailability. <sup>137</sup>Cs activity over the depth of sediments that had been affected by the 100 years flood event in 2013 and the metal distribution in sediment cores indicate a high resuspension potential of at least some of the backwaters. Assuming a probably underestimated average thickness of the resuspendable sediment layer of 20 cm, a flooding event could move 10 mio m<sup>3</sup> of contaminated sediment. Management measures may become necessary, but need to be based on not only exceedance of EQS but also on ecotoxicological responses and a profound system understanding.

## 185

### Do International Dredged Material Frameworks Effectively Assess Risk?

S.E. Apitz, SEA Environmental Decisions Ltd; S. Agius, Environment Canada

The objectives of many countries' Disposal at Sea (DaS) Programs, and of related national and international legislation, mirror the 1996 Protocol to the London Convention (London Protocol) objective "to protect and preserve the marine environment from all sources of pollution and take effective measures, according to their scientific, technical, and economic capabilities, to prevent, reduce, and where practicable eliminate pollution caused by dumping or incineration at sea of wastes or other matter." The development of DaS assessment frameworks for dredged material can involve almost endless possible permutations of action lists, benchmarks, and decision rules. Both individual choices about these parameters, and how they are combined can affect potential regulatory outcomes and the efficacy and fitness for purpose of a DaS action level, tier, or framework. Although the literature is rich with documents on how such approaches should be designed, there are few datasets that are extensive, diverse and representative enough to evaluate how various decision scenarios actually perform in assessing the potential risk of disposal at sea on the marine environment. A database was developed containing co-located sediment chemical and toxicological analytical results that were representative of the range of marine, coastal and estuarine sediment types, and contaminant combinations and levels that might be encountered by a DaS program. After validation and processing, the final database containing 2196 records (for chemistry) and 1081 (for co-located chemistry and toxicity) was designed to enable each record to be "challenged" by a range of DaS decision scenarios, and the results to be analysed. The database was used to test a range of DaS framework options and designs; the relative effectiveness and fitness for purpose of these scenarios was evaluated. Although there are a potentially infinite number of permutations and scenarios, a systematic approach was used to test the potential implications of key questions on chemical action lists, decision rules, and tiered approaches, as well as a comparison of international frameworks. Major findings and their implications to DaS risk assessment will be discussed.

## 186

### Guidance and risk assessment schemes for prospective sediment toxicity testing of organic chemicals

N. Diepens, Wageningen University / Department of Aquatic Ecology and Water Quality Management; h. haveco, Environmental Risk Assessment Team; P.J. van den Brink, Alterra and Wageningen University; M. Van den Heuvel-Greve, Wageningen IMARES / Marine Coastal Systems; A.A. Koelmans, Wageningen University / Aquatic Ecology and Water Quality Management Group; T.C. Brock, Alterra, Wageningen University and Research Centre / Environmental Risk Assessment Team

A framework for prospective risk assessment of sediment-bound organic chemicals is currently lacking. Such a framework requires clearly defined protection goals, evidence-based concepts that link exposure to effects, and a transparent tiered effect assessment. Here, we discuss possible specific protection goals based on the ecosystem services concept for future prospective sediment RA procedures for

organic chemicals in sediment. Benthic organisms provide important ecosystem functions and services, which are similar between freshwater and marine ecosystems. Key drivers for sediment-related ecosystem services are microorganisms, benthic algae, sediment-rooted macrophytes, benthic invertebrates, and benthic vertebrates. Triggers for sediment testing based on chemical properties and toxicity are required. Sediment-spiked laboratory toxicity tests with standard test species should focus on long-term tests with chronic endpoints. The range of taxonomic groups for sediment testing needs to be extended. Prior to actual testing a cost-effective screening based on aquatic toxicity data and equilibrium partitioning is advisable. Assessment factors to be used in tier-1 effect assessment as well as the feasibility of the SSD approach as a tier-2 option are discussed. Micro- and mesocosm experiments with spiked sediment are proposed as a 3<sup>rd</sup> experimental tier. An outlook to unifying information from the various tiers by experimental work, fate modelling, and effect modelling as cost-effective prognostic tools for sediment RA is provided.

## Engineering in vivo fish models for advancing environmental hazard and risk assessment

## 187

### Introduction to the session events and our focus on transgenic models in ecotoxicology

C.R. Tyler, Biosciences College of Life and Environmental Sciences; A. Takesono, J. Moreman, University of Exeter; J. Green, University of Exeter / College of Life and Environmental Sciences; R. Cooper, University of Exeter; A. Foreman; S. Mourabit, A.R. brown, T. Kudoh, University of Exeter

Transgenic fish are applied in ecotoxicology where they have the potential to provide integrated systems for assessing health impacts of chemicals. Zebrafish and medaka are the most popular fish for the generation of transgenic models, due to their high fecundity, transparency of their embryos (zebrafish), rapid organogenesis, and availability of extensive genetic resources. Transgenic fish models are now available to study the effects of heavy metal toxicity (via heat-shock protein genes), oxidative stress (via an electrophile responsive element), various organic chemicals acting through the aryl hydrocarbon receptor, thyroid and glucocorticoid response pathways, and estrogenicity, using a spectrum of different fluorescent markers. Due to variations in their sensitivity, only a few transgenic models are capable of detecting responses at environmentally relevant exposures. Even so, they provide valuable systems to study the biological mechanisms of chemical toxicity. A favoured method for the study of gene expression in transgenic fish is the two step activation Gal4-UAS system. In this system, GAL4 is placed under the control of a desired promoter and UAS is placed next to a desired reporter gene, such as a fluorescent marker; cells producing both components of the system will activate the reporter gene. Transgenic fish systems provide powerful tools for the study of chemical effects, especially in mutant lines lacking skin pigmentation where responses can be visualized in real time and across multiple target tissues in intact organisms. In this presentation we will introduce the topic of transgenic fish for studies in environmental toxicology and provide a viewpoint on future development opportunities, and constraints, for their use in risk assessment.

## 189

### Rapid fluorescent detection of (anti-)androgens with spiggin-gfp medaka

A. Sébillot; P. Damdimopoulou; Y. Ogino; P. Spiranzlova, Watchfrog S.A.; S. Miyagawa, Natural Institute of Natural Sciences; D. Du Pasquier, Watchfrog S.A.; N. Mouatassim; T. Iguchi, National Institute for Basic Biology / Molecular Environmental Endocrinology; G.F. Lemkine, Watchfrog S.A.; B.A. Demeneix; A.J. Tindall, Watchfrog S.A.

Environmental anti-androgen contamination is widespread and has been associated with negative impacts on biodiversity and human health. Our aim was to develop a transgenic medaka model bearing a sensitive and specific androgen responsive fluorescent reporter construct for whole organism-based environmental screening for pro- and anti-androgens. Putative *spiggin* promoters were identified within the genome of the stickleback (*Gasterosteus aculeatus*) and cloned upstream of GFP. A number of putative androgen and estrogen response elements were identified in each promoter. Germinal transgenesis with *spg1-gfp* led to stable medaka lines. GFP induction was restricted to the kidney, the site of spiggin protein production in sticklebacks. Significant dose-dependent *gfp* expression was induced by androgen treatment of newly hatched fry, but not by estrogens, mineralocorticoids, glucocorticoids or progestogens. In addition to flutamide, the biocides fenitrothion, vinclozolin and linuron significantly inhibited 17MT-induced GFP induction, validating the model for detection of anti-androgens. The *spg1-gfp* medaka model provides a sensitive, specific and physiologically pertinent biosensor system for analyzing (anti-)androgenicity of raw chemicals or environmental samples.

## 190

#### **Application of ERE-TG zebrafish in assessing health impacts of oestrogenic EDCs on embryo development and sex differentiation**

T. Kudoh, University of Exeter / Biosciences College of Life and Environmental Sciences; A. Takesono, University of Exeter; O. Lee, University of Exeter / Biosciences College of Life and Environmental Sciences; O. Kah, IRSET; C.R. Tyler, Biosciences College of Life and Environmental Sciences  
We have established an oestrogen biosensor transgenic zebrafish (ERE-GFP TG fish) that detects tissue responses to oestrogenic chemicals via GFP expression *in vivo*. Using this TG fish, we have observed that a variety of tissues respond to oestrogens including the liver, heart, muscle and forebrain. However, the roles of oestrogen signaling in development and functions of these tissues are largely elusive. We found that cells in telencephalon and olfactory bulb express GFP in response to 17- $\alpha$ -ethinylestradiol (EE2) from early stages of neurogenesis and the number of GFP cells subsequently increases in larvae up until they are 2 weeks old. The oestrogen responsive telencephalic neural cells (TC-GFP+ cells) show characteristic polar morphology with radial process, suggesting they may be radial glia cells, well-known neural stem cells. TC-GFP+ cells do not possess immunoreactivity for neuronal markers (acetylated tubulin and HuC), but express a neural stem cell marker Sox2. These data suggest specific roles of oestrogen signaling in neural stem cell development and functions. To further analyse behaviour of oestrogen responding brain cells in normal and polluted environment, we are currently modifying our ERE-GFP TG fish to create different transgenic fish lines. Firstly, we have generated a double transgenic line which responds to oestrogen and express two fluorescent colours derived from two oestrogen responsive promoters (synthetic ERE promoter with mCherry reporter and cyp19a promoter with GFP reporter). Heterozygous [ERE-mCherry] $\times$ [Cyp19a-GFP] embryos show that some cells in olfactory bulb respond to both transgenes upon EE2 exposure, but there are fewer cells of mCherry and GFP double positive cells observed in the posterior part of telencephalon. We are also creating ERE-Kalooop and ERE-GCaMP TG fish lines. Kalooop line would permanently label the oestrogen responding cells, facilitating cell lineage tracing in juvenile to adult stage. Calcium activatable GCaMP fluorescent protein visualises neuronal activity in the oestrogen responding cells. These models will now be applied to help better understand the functional roles of oestrogens in development of the brain and sex differentiation in fish. Findings to date imply heterogenic roles of oestrogen signaling during brain development.

#### **191**

##### **Zebrafish reporters of glucocorticoid and aryl hydrocarbon receptor activity**

D. Gorelick, J.L. King, B.L. Cline, University of Alabama at Birmingham  
Exposure to environmental endocrine disruptors is a significant health concern. Previous work has been focused on detecting estrogens, however other chemical classes, such as glucocorticoids and dioxins, are also relevant contaminants. Here we describe the development of new zebrafish reporters for the detection of glucocorticoid receptor (GR) or aryl hydrocarbon receptor (AhR) activity. Previous zebrafish reporters were limited by low sensitivity or progressive silencing of reporter gene expression. To overcome these limitations, we employed a bipartite reporter system that can amplify signals from GR- or AhR-dependent DNA binding but is less sensitive to DNA methylation and transcriptional silencing. Reporter fish can be used to detect glucocorticoids and dioxins and visualize in which tissues such chemicals act in live zebrafish embryos and larvae. Reporter fish can also be used as substrates for chemical screens to detect tissue-selective GR or AhR modulators. Finally, the reporter system can be modified to detect GR or AhR-dependent gene repression. Ultimately, the reporter strategy described here can be used to visualize the activity *in vivo* of any ligand dependent transcription factor of interest, including those that bind environmentally relevant small molecules such as androgens and progestins.

#### **192**

##### **Development and validation of an OECD test guideline incorporating a transgenic fish model**

F. Brion, INERIS / Ecotoxicology Unit; B. PICCINI, C. TURIER, INERIS; J. Porcher, INERIS / UMRI SEBIO; J. Green, University of Exeter / College of Life and Environmental Sciences; A. TAKESONO, University of Exeter; C.R. Tyler, Biosciences College of Life and Environmental Sciences; E. Fetter, Department of Bioanalytical Ecotoxicology; S. Scholz, Helmholtz Centre for Environmental Research / Department of Bioanalytical Ecotoxicology; J. Nicolau, O. Kah, IRSET  
Concern about the effects of Endocrine Disrupting Chemicals (EDCs) to fish and humans reproductive health has stimulated the development of tests to identify endocrine active substances and quantify their effects. Despite important progress that has been made in that direction during the past decade, one major challenge to ecotoxicology is still to develop specific biological tools that allow rapid and cost-efficient assessment of EDCs for environmental hazard and risk assessment. In 2012, an *in vivo* mechanism-based zebrafish embryo assay was developed (Brion et al., 2012) and called EASZY for Detection of Endocrine Active Substances, acting through estrogen receptors, using transgenic cyp19a1b-GFP Zebrafish embryos. The relevance of the EASZY assay for assessing the estrogenic potency of test substances was evaluated by testing more than 60 chemicals and it was found that, in the EASZY assay, GFP was induced in an ER-specific manner by (i) compounds that bind directly to estrogen receptors as agonists (ii) compounds that require metabolic activation into estrogenic metabolites (iii) aromatizable androgens as

well as some non aromatizable androgens. Since the EASZY assay emerged as a fast, simple, specific and sensitive *in vivo* assay for quantifying the estrogenic potency of chemicals at very early critical developmental stages, a Standard Project Submission Form (SPSF) was submitted by the lead country France to OECD test guidelines program in 2012 and the EASZY was accepted to the Validation Management Group for Ecotoxicity (VMG-Eco) working program in December 2013. The first objectives of the validation were (i) to ensure training persons to conduct the test (ii) to assess the transferability of the transgenic model and the test method to the participating laboratories (iii) to assess the intra- and inter-laboratory reproducibility by testing a set of reference ligands including both positive and negative test substances. At the occasion of this oral presentation the current progress of the validation of the EASZY assay will be presented while considering the strengths (and the limits) of transgenic models for environmental hazard and risk assessment. *Acknowledgement* – Study support by the DRC-50 ‘‘Perturbateurs Endocriniens et impacts environnementaux’’ of the French Ministry of Environment.

##### **Application of a transparent transgenic zebrafish model for chemical testing in a semi-automated image analysis system**

J. Green, J. Metz, A.R. brown, S. Owen, T. Kudoh, University of Exeter; C.R. Tyler, Biosciences College of Life and Environmental Sciences  
Zebrafish have emerged as a powerful tool for use in *in vivo* chemical and drug screening because of attributes including their rapid development, relative transparency, high fecundity, and genetic and morphological similarity to mammals. With fluorescence protein expression linked to specific enzymes or receptors, transgenic zebrafish models offer systems for identifying and quantifying molecular initiating events (MIEs) that may trigger adverse outcome pathways (AOPs). With new automated imaging and image analysis systems being specifically designed or adapted for zebrafish larvae (Pardo-Martin et al. 2010, Romano and Gorelick 2014), the application of transgenic zebrafish models for medium-throughput chemical screening is an emerging prospect. We present a novel transgenic zebrafish model for application in a semi-automated imaging and image analysis system for screening of estrogenic compounds. This system provides quantitative and qualitative analysis of tissue-specific targeting of estrogenic chemicals. This is visualised via a GFP fluorescence response in a well-established transgenic model (Lee et al. 2012) that has been incorporated into a non-pigmented ‘Casper’ phenotype. The Casper phenotype allows for easier tissue identification and reduces issues relating to body orientation and fluorescence signal blocking when imaging. With the increasing need to identify endocrine disrupting chemicals and characterise their effect on tissues and organs in humans and other animals, the Casper estrogen responsive GFP transgenic zebrafish in a semi-automated system offers an excellent tool for screening chemicals for estrogenic activity in whole organisms. **References:** Pardo-Martin C, Chang TY, Koo BK, Gilleland CL, Wasserman SC, Yanik MF (2010) Nat Methods. 7(8):634-6. ##### **Transgenic fluorescent tadpoles for detecting chemical disruption of the thyroid axis**

P. Spirhanzlova, Watchfrog; A.J. Tindall, G.F. Lemkine, D. Du Pasquier, Watchfrog S.A.  
During the last decades, there has been increasing concern about thyroid axis disrupting contaminants present in the environment. As the correct functioning of the thyroid axis is crucial for vertebrate development, it is necessary to develop a rapid method to detect thyroid axis disrupting chemicals. One of the most studied hormone-regulated developmental processes in vertebrates is anuran amphibian metamorphosis, a process associated with great morphological and physiological changes fully dependent on thyroid hormones. Leucine zipper transcription factor (TH/bZIP) is highly up-regulated during metamorphosis of *Xenopus laevis* and can be induced prematurely by thyroid hormones. We developed a transcriptional-based assay for the detection of thyroid axis disruption, which uses transgenic *Xenopus laevis* tadpoles harbouring *gfp* coding sequence under the control of the TH/bZIP promoter. Our test is a rapid and simple solution for screening large number of molecules or testing environmental samples.

##### **Tolerance inheritance to copper in the Perez's frog.**

E. Fasola, CESAM Dept of Biology; R. Ribeiro, University of Coimbra; I. Lopes,

Chemical contamination may lead to the occurrence of genetic erosion in natural populations, and, consequently, may impair their viability under future environmental perturbations. This is of particular concern if the loss of genetic variability is irreversible due, for example, to the contaminant-driven elimination of alleles when chemical tolerance is a fully or incomplete recessive (or incompletely dominant) trait – the recessive tolerance inheritance hypothesis (*sensu* Ribeiro and Lopes, 2013). Accordingly, this work aimed at investigating tolerance inheritance to copper in natural populations of the frog species *Pelophylax perezi*. Twenty egg masses, in Gosner stage 8–10, were collected from a population inhabiting a metal free pond and exposed to copper sulphate plus to a control (FETAX medium). Time to death was registered for each egg, with observations following a logarithmic time scale: 12h00min, 16h57min, 23h57min, 33h49min, 47h46min, 67h29min and 95h19min. For each egg mass, the median lethal time (LT<sub>50</sub>) and respective quartiles (LT<sub>25</sub> and LT<sub>75</sub>) were computed. Subsequently, critically sensitive egg masses (categorized as those with an LT<sub>75</sub> similar or below the average of the set of LT<sub>50</sub> for all egg masses) were identified. The within egg mass variability in time to death responses was evaluated through its relative spread: the difference between the lower and upper quartiles relatively to the median: [(LT<sub>75</sub>–LT<sub>25</sub>)/LT<sub>50</sub>]. If metal tolerance corresponded to a recessive trait then the most tolerant egg masses (both parents being recessive homozygotes) would present relative spreads lower than at least some of those with an intermediate LT<sub>50</sub> (both parents being heterozygotes), which was not the case: no relationship between relative spreads and LT<sub>50</sub> values could be found. Therefore, the recessive tolerance inheritance hypothesis was not supported by the present study. On the contrary most of the masses show a full range of variability in the observed pattern of death per observation. This fact suggests that the possible genetic mechanism of tolerance could be determined by co-dominance.

### ***Xenopus laevis* oocyte maturation is affected by metal chlorides**

S. Slaby, University of Lille / Lille Sciences et Technologies Equipe Régulation des Signaux de Division UGSF UMR Cité scientifique SN Villeneuve d'Ascq France; S. Lemièrre, Fonctionnement des Ecosystèmes Anthropisés; G. Marchand, PRES Univ Lille Nord de France / Univ Lille1; S. Demuynck, LGCgE - EA 4515; A. Gelaude, J. Bodart, University of Lille / Lille Sciences et Technologies Equipe Régulation des Signaux de Division UGSF UMR Cité scientifique SN Villeneuve d'Ascq France; M. Marin, University of Lille1 / Biology

Few studies have been conducted using *Xenopus laevis* germ cells as oocytes, though these cells offer many advantages allowing both electrophysiological studies and morphological examination. The aim of this work was to investigate the effects of metal (cadmium, lead, cobalt and zinc) exposures using cell biology approaches. First, cell survival was evaluated with both phenotypical and electrophysiological approaches. Secondly, the effect of metals on oocyte maturation was assessed by morphological observations (germinal vesicle breakdown: GVBD) and by electrophysiological recordings (calcium-activated chloride currents). From survival experiments, our results showed that metal chlorides did not affect cell morphology but strongly depolarized *Xenopus laevis* oocyte resting potential. In addition, cadmium chloride was able to inhibit progesterone-induced oocyte maturation in a dose-dependent manner. By contrast, we observed that zinc, but also to a lesser extent cadmium, cobalt and lead, were able to enhance spontaneous oocyte maturation in the absence of progesterone stimulation. Finally, electrophysiological recordings revealed that some metal chlorides exposures, such as for lead and cadmium, could disturb calcium signaling in *Xenopus laevis* oocyte by modifying calcium activated chloride currents. Our results obtained with metal chlorides demonstrated that *Xenopus laevis* oocyte provide an interesting lab model to evaluate the toxicity of aquatic contaminants.

### **Risks of progestogens to amphibians - Low ng/L concentrations disrupt egg development**

M. Saffholm, Uppsala University / Dept of Environmental Toxicology; J. Fick, Umea University / Department of Chemistry; C. Berg, Dept. of Environmental Toxicology / Dept of Environmental Toxicology

Several progestogenic pharmaceuticals, including levonorgestrel (LNG), norethindrone (NET), and progesterone (P4), are present in the aquatic environment at low ng/L concentrations. The aim of the present study was to compare the sensitivity of male and female gametogenesis (spermatogenesis and oogenesis) in frogs to impacts of progestogen exposure. *Xenopus tropicalis* males were exposed to LNG and females were exposed to LNG, P4, or NET at concentrations of 0 – 100 ng/L for 4 weeks. The testes were analyzed histologically with respect to frequencies of spermatogonia, spermatocytes, and spermatids, the seminiferous tubule diameter, number of seminiferous tubules, number of germ cell nests, and amount of spermatozoa. Sperm count and sperm motility were determined in fresh testicular samples using a microscope counting chamber. Oocyte maturation was analyzed histologically. All three test substances caused reduced proportions vitellogenic oocytes and increased proportions previtellogenic oocytes compared with the controls, indicating inhibited vitellogenesis. These effects were ascertained at 1 ng/L for NET and LNG and at 10 ng/L for P4. No significant impact on the proportions of spermatogonia, spermatocytes, or spermatids in the testes, or on sperm count or sperm motility was detected. The results imply that spermatogenesis

and sperm quality are much less sensitive to progestin toxicity than oogenesis in amphibians. Taken together our data show that vitellogenesis is a sensitive target for progestogens and that female reproduction may be at risk in exposed wild frog populations.

### **Early life stage developmental effects of elevated maternal dietary selenium exposure in amphibians**

A.J. Masse, Toxicology Centre / Toxicology; D.M. Janz, University of Saskatchewan / Toxicology Centre; J.R. Muscatello, Stantec / Department of Toxicology

Selenium (Se) is a contaminant of potential concern in aquatic systems located downstream of mining operations due to its efficient incorporation into food webs, potential for bioaccumulation at higher trophic levels, and role as a developmental toxicant in oviparous vertebrates. Adverse reproductive effects of Se have been the primary focus of research in fish and bird species; however studies focusing on Se toxicity in amphibians are lacking, particularly early life stage toxicities and tissue-based toxicity thresholds. The objective of this study was to determine dose-response relationships for early life stage toxicities in *Xenopus laevis*. Following a 68 day dietary exposure to food augmented with L-selenomethionine at measured concentrations of 0.7 (control), 10.9, 30.4, and 94.2 µg Se/g dry mass (d.m.), adult female *X. laevis* (n=9–10 per treatment) were bred with untreated males. Evaluations in the resulting eggs/embryos included Se concentrations, fertilization success, hatchability, survival, developmental rates, and the frequency and severity of Se-induced malformations. Percent hatchability of embryos and survival of embryos/tadpoles up to 5 days post-fertilization (dpf) were significantly reduced in the 30.4 µg Se/g treatment group compared to the control group ( $p < 0.05$ ). The measured Se concentration in subsamples of 100 eggs per female showed mean values of 1.6, 10.8, 28.1 and 81.7 µg Se/g d.m. for treatment groups receiving 0.7, 10.9, 30.4, or 94.2 µg Se/g d.m. in their diet, respectively. Analysis of 5 dpf tadpoles showed that abnormalities relating to craniofacial, vertebral, gut, and lens structures were prevalent in addition to the occurrence of edema and eye pigmentation. Both the frequency and severity of abnormalities were significantly increased in the 5 dpf tadpoles from the 81.7 µg Se/g embryo d.m. group when compared to the control ( $p < 0.001$ ). A strong positive relationship between the frequency of total abnormalities and egg selenium concentration was observed ( $r^2=0.878$ ,  $p < 0.001$ ). Future work will include an assessment of oxidative stress biomarkers in 5 dpf tadpoles to evaluate potential effects on antioxidant defense mechanisms and its relation to Se-induced malformations. Overall, this study aims to aid in further understanding the sensitivity of amphibians to Se, with the goal of developing environmentally relevant toxicity thresholds.

### **Understanding the population-level consequences of copper toxicity and climate variability on amphibians inhabiting contaminated environments**

S.M. Weir, Savannah River Ecology Laboratory / Savannah River Ecology Laboratory; C.J. Salice, Towson University / Biological Sciences Environmental Science; D. Scott, S.L. Lance, University of Georgia / Savannah River Ecology Laboratory

A great deal of amphibian ecotoxicity data has been generated in the last 15 years, with excellent insights obtained from both laboratory and mesocosm studies. In wild populations, however, the relationship between individual-level contaminant effects and population persistence remains unclear; i.e., a single instance of exposure to lethal or sublethal effects will not necessarily translate into population-level declines. A powerful tool to investigate the population-level consequences of contaminant toxicity is to incorporate the toxicity data into population models. Here we present a stochastic matrix population model for toads inhabiting a copper-contaminated environment. We parameterize the model with published demographic data available for the southern toad (*Anaxyrus terrestris*) and other *Anaxyrus* species when southern toad data were not available. We also use data from a long-term study on the Savannah River Site (SRS) to provide a range of values for parameters for which no previous toad data are available. We used laboratory-generated toxicity data to inform adjustments to survival parameters for embryos and larvae in the model. We investigated a range of copper concentrations that correspond to laboratory data and the full range of survival (0–100% survival) for embryos and larvae. We also incorporated catastrophic reproductive failure which has previously been shown to be important for amphibian population persistence. Data collected on the SRS suggests that the probability of catastrophic reproductive failure is increasing in recent years. We incorporate stochasticity into all parameters in the model, except larval survival which was determined by a density dependent function. Our results suggest that copper toxicity in the embryo and larval stages is compensated by density dependence, so has little effect until complete mortality (i.e., 100% larval mortality). Catastrophic reproductive failure is a more important parameter in terms of affecting population persistence, which has been reported previously and is quickly coming to consensus. Future research efforts include modeling additional species (and associated copper toxicity) while also adopting a metapopulation approach to model a landscape of wetlands that vary in failure probabilities.

### **Occurrence and accumulation of contaminants in amphibians in diverse**

## landscapes across the United States

K.L. Smalling, E. Muths, E. Grant, G. Fellers, US Geological Survey; P. Kleeman, US Geological Survey / Western Region Ecological Center

Contaminants, acting singly or in combination with other stressors, are one of several potential causes of amphibian population declines. Surveys of amphibian populations have shown correlations between declines and proximity to both agricultural and urban lands. Moreover, contaminants are considered important cofactors that can decrease immune system responses, potentially increasing disease prevalence in local populations. The US Geological Survey has been conducting field studies throughout the United States designed to address the occurrence of contaminants in amphibian habitats and their accumulation in tissues to begin to understand the potential impacts on populations. Novel screening techniques are being utilized to assess the biological activity and inorganic composition of amphibian habitats in the Northeast to help prioritize areas of interest biologically and chemically for more in depth studies. As part of these studies, habitat quality (water and sediment) and amphibian health (accumulation into tissues) are being assessed in a variety of landscapes including remote high elevation locations in the Sierra Nevada Mountains, agriculturally dominated wetlands in Iowa, and National Wildlife Refuges and National Parks in the Northeast. In agricultural areas, the occurrence of pesticides in habitat and the accumulation in tissue was significantly correlated with land-use within a 5 km buffer of the wetlands. However, in remote and/or protected areas habitat quality and tissue body burdens was not correlated with the surrounding land-use because atmospheric transport is considered the dominant source of contaminants to these areas. From an ecosystem health standpoint, results suggest that amphibians are accumulating a wide variety of contaminants including several pesticides not previously reported in tissue. Although the types and concentration of contaminants detected in tissues varied by study area, the information gained will help prioritize particular compounds of interest for future studies. Amphibians residing and breeding in many of these diverse landscapes are exposed to contaminants throughout their lifecycle, and the potential effects on the population are still unknown. Future research is needed to understand the interaction between contaminants and other stressors such as disease, at the population level.

## Interpreting Biological Effects of Metals and Their Mixtures (I)

### 202

#### **Metal mixture complexity: The antagonistic action of a Ni-Zn-Cu mixture to *C. dubia* becomes additive when Cd is added**

C. Nys, University of Ghent / Laboratory for Environmental Toxicology and Aquatic Ecology GhEnToxLab unit; C. Janssen, University of Ghent / Laboratory of Environmental Toxicology and Aquatic Ecology GhEnToxLab unit; R. Blust, University of Antwerp / Systemic Physiological and Ecotoxicological Research Department of Biology; E.E. Smolders, Katholieke Universiteit Leuven / Division Soil and Water Management; K.A. De Schampelaere, Ghent University (UGent) / Laboratory for Environmental Toxicology and Aquatic Ecology GhEnToxLab unit

There is a need for more understanding about combined and interactive effects of metal mixtures during chronic exposure to be able to incorporate metal mixture toxicity effects into risk assessment procedures. Therefore, we investigated the possible interactive effects in ternary and quaternary mixture combinations of metals; Ni-Zn-Cu and Ni-Zn-Cu-Cd, respectively, on reproductive toxicity to *Ceriodaphnia dubia* using a ray design in a modified natural water (l'Ourthe Oriental, Belgium; pH=7.3, Dissolved organic carbon= 7.3 mg/L and hardness=84 mg CaCO<sub>3</sub>/L). Furthermore, we also investigated the influence of varying the metal concentration ratios within the ternary mixture on the magnitude of the interactive effects. Interactive effects were significantly antagonistic according to both the Independent Action (IA) and Concentration Addition (CA) model in the ternary Ni-Zn-Cu mixture. However, the type of interactive effect was dependent on the applied mixture concentration. At low mixture concentrations treatments, IA and CA predicted relative reproduction (RR) were not significantly different from observed RR, i.e., additive. When Ni, Zn and Cu were combined at higher mixture concentrations treatment specific significant antagonistic effects started to occur for both IA and CA. Varying the metal concentration ratios in the ternary mixture did not result in significant differences in the magnitude of the antagonistic effect. However, when Cd was added to the mixture combination, the global mixture effect became additive. The results of this study point out that there is a clear need to better mechanistically (e.g. physiologically) understand metal mixture interactions. Nonetheless, both CA and IA provide conservative models for predicting for *C. dubia* reproductive toxicity in Ni-Zn-Cu and Ni-Zn-Cu-Cd mixtures.

### 203

#### **Interaction between nickel and cobalt toxicity in *Enchytraeus crypticus* is due to competitive uptake**

E. He, VU University Amsterdam / Department of Ecological Science; J. Baas, Centre for Ecology & Hydrology; C. van Gestel, VU University Amsterdam / Ecological Science

Uptake and toxicity of Ni-Co mixtures in *Enchytraeus crypticus* were determined after 4, 7, 10 and 14 d exposure in solutions embedded in an inert sand matrix. Generally, body concentrations of Ni and Co increased with increasing exposure

concentrations. Ni body concentration was significantly reduced in the presence of Co, while Ni only marginally affected Co uptake. When expressed as free ion activities, individual toxicity of Ni and Co increased with time, with LC50s decreasing from 78.3 and 511  $\mu\text{M}$  at 4 d to 40.4 and 393  $\mu\text{M}$  at 14 d, respectively. When expressed as body concentrations, LC50<sub>BodyNi</sub> remained constant with time whilst LC50<sub>BodyCo</sub> increased during the first 7 d but remained stable afterwards. As identified by the MIXTOX model, interactions between Ni and Co were mainly antagonistic when based on free ion activities, however, no interaction was observed when based on body concentrations. A process-based model, incorporating exposure time to analyse the mechanisms underlying the dynamic mixture toxicity confirmed the differences in toxicokinetics of the two metals. Our findings suggest that body concentrations, which incorporate the bioaccumulation process, are time-independent and can act as a more constant indicator of metal toxicity. The observed antagonism was mainly caused by competition between Co and Ni for binding sites and subsequent inhibition of Ni uptake. This competitive interaction occurred at the uptake level (toxicokinetics), but not at the target level (toxicodynamics).

### 204

#### **Metal uptake and toxic growth effects in *Lemna minor* exposed to varying mixtures of uranium and cadmium**

N. Horemans, Belgian Nuclear Research Centre (SCK-CEN) / Biosphere Impact Studies; M. Van Hees, Belgian Nuclear research centre (SCK-CEN); a. van hoeck; H. Vandenhove, Belgian Nuclear Research Centre SCKCEN / Biosphere Impact Studies; C. Svendsen, CEH, Wallingford / Pollution and Ecotoxicology

As sessile organisms, plants are commonly exposed to a number of adverse conditions in their environment. Nuclear energy production encompasses a variety of industrial activities, from mining and milling of fuel through to power generation and waste management. These nuclear processes release low amounts of radioactive substances together with non-radioactive substances (e.g., heavy metals, organic chemicals). In the present study the effect of combinations of two toxic heavy metals cadmium and the radionuclide uranium was studied on the freshwater macrophyte *Lemna minor* plants at varying mixture ratios and effect levels. The mixture experiment followed a classical ray design based on U and Cd being present in 0U:3/3Cd, 1/3U:2/3Cd, 1/2U:1/2Cd, 2/3U:1/3Cd or 3/3U:0Cd ratio's, based on their respective IC<sub>50</sub>s, and the concentration ranges chosen based on initial single metal dose response experiments. Within the tested concentration range the presence of Cd had no influence on the U accumulation into the plants. Contrastingly, Cd uptake was significantly lowered in the presence of U, indicating that U blocks the uptake of Cd into the plants. As it is yet unknown how U accumulates in plants more research is needed to mechanistically understand the effect of U on Cd uptake. Based on nominal concentrations an EC10 value of 1.5  $\pm$  0.2  $\mu\text{M}$  and an EC50 value of 24.1  $\pm$  1.4  $\mu\text{M}$  was estimated for Cd and 6.5  $\pm$  0.9  $\mu\text{M}$  and 29.5  $\pm$  1.9  $\mu\text{M}$  for U, respectively. Hence toxicity of Cd and U is in the same order of magnitude. Possible interacting effects of U and Cd in the binary mixture were assessed using the MIXTOX model as described by Jonker et al. 2005. It was shown that independent of the reference model chosen a strong dose ratio dependent antagonism was observed when the toxicity data were expressed on the nominal U and Cd concentrations, while when effects were expressed against the measured medium U and Cd concentrations (i.e. taking into account media metal chemistry) in the toxicity calculations this interactive effect was no longer present. When expressing toxicity against U and Cd levels in the plants the ratio specific antagonism reappeared. The findings of this study indicate interactions are occurring between Cd and U both in the medium, during uptake and once internalized. The implications of these findings in terms of the potential mechanisms and predictive risk assessment will be further discussed.

### 205

#### **Ni & Zn increase the sensitivity of mussel larvae to Cu: implications for risk assessment and the design of mixture toxicity experiments**

D. Deruytter, University Ghent / Laboratory for Environmental Toxicology and Aquatic Ecology GhEnToxLab unit; K.A. De Schampelaere, Ghent University (UGent) / Laboratory for Environmental Toxicology and Aquatic Ecology GhEnToxLab unit; N. Nevejan, Ghent University / Laboratory of Aquaculture and ARC; C. Janssen, University of Ghent / Laboratory of Environmental Toxicology and Aquatic Ecology GhEnToxLab unit

In polluted areas (e.g. harbours) mussels are frequently exposed to a mixture of different metals. Fortunately, according to available literature, mussel larvae rather insensitive to most metals (e.g. Zn, Ni, Cd, ...) with NOEC concentrations much higher than the environmental concentrations. However, mussel larvae are one of the most Cu sensitive marine species, implying possible adverse effects of currently measured Cu concentrations. It is unknown what happens when mussel larvae are exposed to elevated Cu concentrations in combination with low (individually harmless) concentrations of other metals. To assess the influence of binary mixtures on mussel larvae development, a total of 6 full factorial experiments (between 6\*6 and 7\*11) were performed. Each experiment was conducted according to the ASTM E 724-98 guidelines. Each experiment was performed at least twice to ensure reproducibility of the results. R statistics was used to analyse the results, calculate the EC50's and determine whether or not there is synergism or antagonism. The individual EC50's found in this study are similar to the values reported in the literature. The influence of Zn on the Cu toxicity can be predicted

well, based on the concentration addition model although some antagonistic effects are observed at low Cu concentrations. This is not the case for the Cu/Ni mixture. On the one hand, there is a strong synergistic effect on Cu toxicity when the larvae are exposed to Ni concentrations as low as 2–5% of the Ni EC50 (8–20 µg Ni/L). On the other hand, high Ni concentrations (> 200 µg/L) have an opposite (antagonistic) effect. The dose level-dependent effect of the mixtures described above was reproducible over the different experiments. In general the results indicate that a high tolerance to a certain chemical (e.g. Ni) does not automatically mean that this chemical is harmless. It is important to test low (environmentally realistic) concentrations in mixture studies. If only a more conservative Cu/Ni experimental design would have been assessed (e.g. NOEC, EC10,...), the synergism at low Ni concentrations would have been missed. For risk assessment purposes: the CA model can be used to predict the effect of Cu/Zn mixtures as only antagonistic interactions were observed. CA and IA cannot be used to predict the effect of Cu/Ni mixtures because synergistic effects occur at low concentrations.

206

#### Does chronic toxicity of Cu and Zn to *Daphnia magna* depend on temperature?

C.S. Pereira, Laboratory of Environmental Toxicology and Aquatic Ecology Ghent University GhEnToxLab; C. Janssen, University of Ghent / Laboratory of Environmental Toxicology and Aquatic Ecology GhEnToxLab unit; R. Blust, University of Antwerp / Systemic Physiological and Ecotoxicological Research Department of Biology; K.A. De Schampelaere, Ghent University (UGent) / Laboratory for Environmental Toxicology and Aquatic Ecology GhEnToxLab unit Ecological risk assessment (ERA) is based on conventional ecotoxicological tests that are usually performed at a standard temperature. A shift away from this standard temperature can have an impact on the sensitivity of the organisms to metal stressors. The main goal of this research was to determine if chronic metal toxicity to *Daphnia magna* depends on temperature, since few studies are available about the influence of temperature on metal toxicity on *Daphnia* and temperature acclimation is often not considered. In this study, the chronic toxicity of copper (Cu) and zinc (Zn) on *Daphnia magna* at 15°C, 20°C, and 25°C was studied. Four clones from a single population of *D. magna* were acclimated at the same temperature that the 21d-*Daphnia magna* reproduction tests for Cu and for Zn was performed, 15°C, 20°C, and 25°C. *D. magna* clones present different sensitivities to Copper and Zinc. At 20°C the 21 days EC50 values for Cu varied between 40 and 51 µg Cu (dissolved)/L. For Zn at 20°C the 21 days EC50 values varied between 114 to 153 µg Zn (dissolved)/L. Zinc toxicity to *D. magna* depended on temperature. For total reproduction the 21 days EC50 values for Zn were lower at 15°C and higher at 25°C compared with 20°C, 1.4 fold variation. For Cu the 21 days EC50 and EC10 values presented on average a 1.4 and 1.5 fold of variation between 15 and 25°C, respectively. Compared with the values at 20°C the 21 days EC50 for Cu were lower at 15°C and similar at 25°C. Therefore the highest toxicity of Cu on *D. magna* was observed at the lowest temperature 15°C. The 21 days EC10 values for Cu at 20°C and 25°C were higher than the 21 days EC50 at 15°C. However, for Zn this was not observed. Even then, these results raises concerns since the EC10 for Cu at 20°C that is considered in ERA may not be protective at 15°C. Our results indicated that chronic toxicity of copper and zinc on *Daphnia magna* depends on temperature. Cu and Zn chronic toxicity on *D. magna* were higher at a lower temperature. Therefore the influence of temperature on metal toxicity should be considered in models like the Biotic Ligand Model (BLM).

207

#### Effects of climate change on the toxicity of metal-polluted soils to *Enchytraeus crypticus*

M. González-Alcaraz, Faculty of Earth and Life Sciences, VU University / Ecological Science; E. Tsitsiou, Faculty of Earth and Life Sciences VU University / Dept of Ecological Sciences; R. Wieldraaijer, R. Verweij, Faculty of Earth and Life Sciences VU University / Department of Ecological Science; C. van Gestel, VU University Amsterdam / Ecological Science

The aim of the present study was to assess the effects of climate change (temperature and soil moisture content) on the toxicity of metal-polluted soils. Bioassays with *Enchytraeus crypticus* (a soft-bodied Oligochaete living in contact with the soil solution and the contaminants present in soil) were performed in soils polluted by metal mine wastes with different characteristics (mine tailing, forest and intermittent watercourse). Dilution series of the soils were prepared with Lufa 2.2 soil, and tested under different combinations of temperature (20 and 25 °C) and soil moisture content (50 and 30% of the soil water holding capacity). Survival and reproduction were determined as endpoints. Our hypothesis was that an increase in ambient temperature and a decrease in soil moisture content would affect the toxicity of metal-polluted soils to *E. crypticus*, enhancing its susceptibility. The soil from the mine tailing had a sandy loam texture, neutral pH (7.44), high electrical conductivity -EC- (2.22 mS cm<sup>-1</sup>), low content of organic carbon -OC- (0.87%) and low cation exchange capacity -CEC- (10.0 cmol<sub>c</sub> kg<sup>-1</sup>). The forest soil showed a clay loam texture, neutral pH (7.24), low EC (0.39 mS cm<sup>-1</sup>), high content of OC (5.69%) and high CEC (28.2 cmol<sub>c</sub> kg<sup>-1</sup>). The soil from the watercourse had a loam texture, slightly acidic pH (6.04), high EC (2.43 mS cm<sup>-1</sup>), low OC content (2.52 %) and low CEC (13.1 cmol<sub>c</sub> kg<sup>-1</sup>). The three soils had high concentration of total metals (in mg kg<sup>-1</sup>): Cd~16-33, Cu~66-177, Pb~5500-6500 and Zn~8000-9800. The undiluted soil from the mine tailing showed high concentrations of available

(extracted with 0.01M CaCl<sub>2</sub>) Cd (1976 µg kg<sup>-1</sup>) and the watercourse soil of Pb (807 µg kg<sup>-1</sup>) and Zn (31020 µg kg<sup>-1</sup>). No effect was observed on enchytraeid survival (average survival ≥80%). Reproduction was the most sensitive endpoint, and it was reduced by 65-98% compared to the control (Lufa 2.2 soil) in the watercourse soil (lower pH, higher salinity and higher available metal concentrations). In this soil, EC50 and EC10 significantly decreased with decreasing soil moisture content. In the other soils, reproduction was reduced by < 50% compared to the control. The present study shows that lowering soil moisture content has the strongest effect on the toxicity of metal-polluted soils. The toxicity of different soils polluted by metal mine wastes under a climate change scenario will depend on soil properties (e.g. pH, salinity) and available metal concentrations.

## Plastics in the Aquatic Environment: Mechanisms and Implications (I)

208

#### Microplastics in the Arctic

A. Lusher, Galway-Mayo Institute of Technology / Marine and Freshwater Research Centre; V. Tirelli, National Institute of Oceanography and Experimental Geophysics; I. O'Connor, R. Officer, GalwayMayo Institute of Technology Globally, microplastics are an emerging marine pollutant. Ocean currents are probably responsible for the distribution of microplastics to almost every marine habitat around the world; with plastic composition and environmental conditions significantly affecting their distribution. With regards to the Arctic, microplastics have previously been identified in ice core samples, although the route of transport is probably due to water currents. During the present study, we used two different methods to assess the levels of microplastics in the Arctic waters, underway sampling and a manta net. Sampling was carried out on the R.V. G.O. Sars as part of a Eurofleets2 funded cruise in surface waters from southwest of Svalbard. The results have been combined with oceanographic information and biological data to understand whether there is an oceanic influence on the number of particles found. It is the first report of microplastics in a highly productive polar area; further studies need to address organisms that might be interacting with microplastics, to understand whether the levels of microplastics are having any effect on the biota in the area.

209

#### Waste water treatment plants (WWTP) as a source of microplastics in the aquatic environment

F. Murphy, University of the West of Scotland / School of Science; C. Ewins, University of the West of Scotland / Institute of Biomedical and Environmental Health Research; B. Quinn, Irish Centre for Environmental Toxicology (ICET) / Institute of Biomedical and Environmental Health Research Municipal effluent discharged from waste water treatment plants (WWTP) may be a significant contributor of microplastics to the environment as many face wash products can contain plastic microbeads; also the simple act of washing clothes made of synthetic fabric is capable of releasing thousands of fibres into the waste water. The ability of WWTP to remove these microplastics is therefore important in preventing its release into the environment. A secondary WWTP located on the River Clyde, Glasgow serving 650,000 people was sampled at different stages of the treatment process. Three stages of the treatment process were sampled; before fine screening, after primary settlement, and the final effluent, before it is released to the River Clyde. 10L steel buckets were lowered into the water to collect the samples, this was then passed through a plankton net (45µm) and/or a steel sieve (65µm) to collect any debris present. This debris was then washed into clean glass bottles, and then vacuum filtered. Any potential microplastics present were then identified using Fourier Transform Infrared Spectrometry (FT-IR). Preliminary results show that microplastics are being released from this treatment plant within the final effluent. The average amount of microplastics released per liter was calculated as 0.09. Using flow rates for the plant it was estimated that 22,181,090 microplastics per m3 could potentially be released as effluent into the River Clyde everyday, or 924,212 MP/Hour. Three different polymers have been identified thus far; polyester, polyamide, and acrylic. The majority of the microplastics found have been flakes, the rest being fibres. The microplastics ranged in size from 0.2-2.55mm. However at present it is unknown how this compares to the amount of microplastics entering the treatment plant. Samples taken before fine screening are in the process of being analysed to determine the amount of microplastics present. The amount of microplastics present after primary treatment will also be determined in order to compare the extraction efficiency of microplastics between the two treatment levels (primary & secondary). Comparing the amount of microplastics entering the treatment plant with what is being released will provide a valuable insight into the effectiveness of WWTP in the removal of microplastic debris.

210

#### Microplastic contamination in an urban area: case of the Greater Paris

R. Dris, LEESU laboratoire eaux environnement et systèmes urbains; J. Gasperi, LEESU / Leesu; N. Furmanski, Unilever / Direction du Développement et de la Prospective; M. Saad, Université ParisEst LEESU UMRMA UPEC ENPC AgroParisTech UPEMLV; B. Tassin, Paris-Est University / LEESU laboratoire

Microplastics have been defined as particles < 5 mm. While many efforts were deployed for the assessment of marine microplastic pollution, there has been limited focus on the plastic contamination of continental hydrosystems: microplastic sources and dynamics remain largely unknown. This study investigates the microplastic contamination in Greater Paris, considering the microplastic fluxes both on the catchment in the atmosphere and in wastewater, and in the receiving water system. These first investigations on urban environment confirm the presence of microplastics in sewage, freshwater and total atmospheric fallout and provide knowledge on the type and size distribution of microplastics in the [100 – 5 000 µm] range. Whatever the urban compartment considered, microplastics were indeed observed. For the first time, microplastics, mostly fibers, were found in atmospheric fallout (29-280 particles/m<sup>2</sup>/day). High levels of fibers were also found in wastewater (260-320 x10<sup>3</sup> particles/m<sup>3</sup>). In treated effluents, the contamination significantly decreases to 14-50 x10<sup>3</sup> particles/m<sup>3</sup>. No millimetric fiber was observed in treated effluent attesting to their removal. In river Seine, two sampling devices are used to collect both large and small microplastic particles: i) a plankton net (80 µm mesh size) and ii) a manta trawl (330 µm mesh size). Sampling with the plankton net shows a predominance of fibers with concentrations ranging from 3 to 108 particles/m<sup>3</sup>. A greater diversity of both microplastic shapes, sizes, and types is encountered during manta trawl sampling but at much lower concentrations (0.28-0.47 particles/m<sup>3</sup>). This combined approach could be relevant and implemented in future studies to provide an accurate overview of microplastic distribution in freshwater.

## 211

### Microplastics in Swiss surface waters, and going upstream: nature, concentrations, interaction with pollutants

F. Faure, C. Demars, EPFL Swiss Federal Institute of Technology in Lausanne / Central Environmental Laboratory; O. Wieser, EPFL; M. Kunz, Federal Office for the Environment FOEN; L. De Alencastro, École Polytechnique Fédérale de Lausanne / Central Environmental Laboratory  
Marine microplastic (< 5 mm) water pollution has met growing public and scientific interest in the last years. The situation in freshwater environments remains largely unknown, although they appear to play an important role as part of the origin of marine pollution. Apart from the physical impacts on biota, chemical effects are to be expected as well, especially with smaller particles. This study aimed at assessing the situation for the Swiss Lakes Geneva, Constance, Neuchâtel, Maggiore, Zurich and Brienz, and identifying potential impacts. Lake surface transects, a few rivers as well as urban runoff outlets and WWTPs have been sampled using a floating manta net, and beach sediments have been analysed. Plastics have been sorted in types (fragments, pellets, cosmetic beads, lines, fibres, films, foams) and composition (PP, PE, PS, etc.). Fishes and water birds have been dissected to assess their potential exposure, and analyses of the hydrophobic micropollutants adsorbed to the microplastics as well as some potentially toxic additives they contained have been conducted. It appears that all lakes are affected by this pollution, microplastics of all types and diverse composition having been found in all samples. Birds and fishes are prone to microplastic ingestion, and all the tested chemicals (both adsorbed micropollutants and contained additives) were found above the detection limit, and often the quantification limit. The sources and their respective contribution need to be confirmed and quantified, and the ecotoxicological impacts also need further investigation. Other questions remain open, including the transport and fate of the plastic particles in the environment.

## 212

### Combined effects of UV exposure and mechanical abrasion on microplastic fragmentation by polymer types

Y. Song, Oil and POPs research group; W. Shim, S. Hong, Korea Institute of Ocean Science and Technology / Oil and POPs research group; M. Jang, Korea Institute of Ocean Science and Technology / oil and POPs research group OPRG; G. Han, Oil and POPs research group; M. Rani, S. Jung, Korea Institute of Ocean Science and Technology  
Fragmented secondary microplastic particles account for the majority of microplastics in the field and have various origins, which makes proper control to be difficult. Scientific information is, however, quite limited, and this hypothesis is not tested yet. Therefore, effects of UV irradiation and (or) mechanical abrasion on fragmentation of polyethylene (PE), polypropylene (PP) and expanded polystyrene (EPS), the top three polymer types in marine debris monitoring study, was evaluated in laboratory condition. The apparent surface damage of PE and PP pellets and EPS spherules exposed to UV for 180 d was observed by SEM, FT-IR microscope and naked eyes. The surface damage of PP was faster than PE. After 120 d, the cracks on the surface of PE could be identified by naked eyes, while, after 60 d, the weakened PP was embrittled and easily broken down and fine cracks appeared. In case of EPS, yellow color appeared on 60 d after UV exposure and the surface was embrittled and started to create the fine particles on the surface. In the only mechanical abrasion experiment for 60 d, the average fragmented particles per bottle produced from PE, PP and EPS were 174±51, 214±14 and 57,339±7,504, respectively. In combination of UV exposure and subsequent mechanical abrasion for 60 d, the mean fragmented particles from PE, PP and EPS were 73±49, 1,442±123 and 723±134, respectively. In case of PE, 60 days of exposure period to UV was not long enough to reach at the critical point for photooxidation causing

physical alteration in PE. In the PP, number of fragmented particles produced from combination of UV exposure and mechanical abrasion. Because of UV exposure, the occurrence of chemi-crystallization led to embrittlement of PP. The final size of the EPS spherules after combined experiment was smaller than that of only mechanical abrasion experiment, while number of fragmented particle showed reversed results. It is not clear whether visible white flour of EPS fragments on the surface of spherules were lost during size and weight measuring process or UV exposure experiment rather changed polymer chemistry of EPS resistant to mechanical abrasion. **Keywords: microplastics, fragmentation, mechanical abrasion**

## 213

### Plastic particulate pollution: a multi-scale pollution

f. lagarde, Institute of molecules and materials of Le Mans / Institute of Materials and Molecules of Le Mans IMMM UMR CNRS; P. Daniel, University of Le Mans / Insitut des Molecules et Materiaux du Mans IMMM

Plastic pellets, fibers and fragments originating directly from industry and domestic sewers are classified as primary source of plastic pollution. The secondary source of plastic particles result from the fragmentation processes of large plastic items after a long time in the environment. At the moment, despite the worldwide distribution of plastic fragments, the global load of plastic on the open ocean surface was estimated to be far less than expected. One of the serious hypotheses regarding the "missing" plastic is that the fragmentation processes may finally lead to sub micrometric fragments. However, while data on microplastics presence in the environment increase rapidly, smaller sub-micrometric fragments could not be quantified so far. Indeed, studying nano fragments requires very specific analytical tools and procedures. Studies on all fragments of plastic, from nano to milli-size, are now of major importance to understand the sources and fate of plastic pollution. In this work, High Density Polyethylene (HDPE) and polypropylene (PP) films were fragmented by high-energy milling in order to generate fragments. The milling was processed at liquid nitrogen temperature to decrease elasticity of the polymers as, after long time in the environment, polymers become more brittle before fragmentation. Generated fragments were characterized by laser granulometry and found to be mostly composed of micro-sized fragments with average sizes depending on the milling conditions but also on the polymer type. This work suggests that, depending on the polymer type, from 20 to 70% of the particles obtained from fragmentation of a plastic item are smaller than 330 µm, which is the size mesh the most often used to collect environmental samples. In all cases, nano-scale particles were detected as only a few percentage (less than 1%). However, after appropriate sieving, the use of several techniques dedicated to nano-scale analysis revealed that nano fragments were present. We will present here the results obtained with TEM, SEM, DLS and Raman microspectroscopy on nano fragments of plastics in aqueous media. This work is a first insight in the understanding of plastic fragmentation processes with a first attempt to determine the sizes of particles that fragmentation may generate. It emphasizes that there is a urgent need to sample and characterize microplastics under 330 µm and nanoplastics to determine the "real" levels of pollution in the environment.

## Latest advances in passive sampling and dosing (I)

## 214

### POCIS: Love'em or Hate'em

C.D. Metcalfe, Trent University / Water Quality Centre; T. Sultana, Trent University / Environmental and Resource Studies

The Polar Organic Compounds Integrative Sampler (POCIS) is a passive sampler which can be used to estimate time-weighted average concentrations of chemicals over deployment periods that are typically over several weeks. Sampling rates for individual chemicals determined in the laboratory or *in situ* are used in conjunction with theoretical uptake models to provide estimates of the concentrations of the chemicals in water. Like other passive sampling techniques, POCIS offers several advantages over conventional monitoring techniques, including the ability of these devices to pre-concentrate contaminants to easily detectable levels, the low matrix effects from analysis of the extracts, and the relative stability of compounds once adsorbed on the solid phase. However, there is still resistance within the scientific and regulatory community to accepting POCIS as a reliable monitoring technique. This resistance stems primarily from uncertainties over the applicability of sampling rates (Rs) determined in the lab to the actual sampling rates in the field, which are influenced by variations in temperature, flow/turbulence, biofouling, etc. In this presentation, I will critically examine the trade-offs made in accepting the limitations of POCIS versus the limitations for conventional sampling of surface waters and drinking water. Analysis of data from the literature shows that variations in Rs values estimated using lab-based or *in situ* techniques typically vary by less than an order of magnitude. Using data generated from our POCIS monitoring in Canada, I will show that the choice of Rs value produces relatively little variation in estimates of the time weighted average concentrations of selected contaminants of emerging concern in surface waters. An argument will be made that these limitations are far less problematic than the uncertainties of monitoring surface waters and drinking water by grab sampling.

## 215

**Use of polar passive sampling in compliance with WFD monitoring networks**  
g. poulier, Irstea / Unité de recherche REBX; S. Lissalde, Université de Limoges / Groupement de recherche eau sol environnement; A. Charriau, Laboratoire GRESE, Université de Limoges; R. Buzier, Université de Limoges / Groupement de recherche eau sol environnement; F. Delmas, Institut national de recherche en sciences et technologies pour l'environnement et l'agriculture; A. Moreira, Irstea / Unité de recherche REBX; G. Guibaud, Université de Limoges / Groupement de recherche eau sol environnement; N. Mazzella, Irstea

This contribution discusses the possible application of POCIS data in the regulatory monitoring programme for pesticides. It focuses on one of the main requirements of the WFD, *i.e.* determination of uncertainty, a key factor for all monitoring programmes. It is assumed that if this parameter is known, POCIS data could be used to complement or replace grab water samples in the context of operational and surveillance monitoring. A confidence interval related to the POCIS data was evaluated and we concluded that it might be up to 138 %, which is higher than European union requirements. However, this issue was adequately counterbalanced by lowering the limits of quantification, as well as a gain of temporal representativeness. Comparison with data from the regulatory monitoring program from French Water Agency showed that the POCIS is already suitable for both operational and investigative monitoring. The sampled fraction issue, and then compliance with Environmental quality standards, was also addressed. We confirmed that POCIS samples only the dissolved fraction and showed that for compounds like atrazine, desethylatrazine and metolachlor, the POCIS concentration is equivalent to the total water concentrations. Finally, an innovative schematic procedure for using passive sampler data, in compliance with the framework of regulatory monitoring programs, was suggested.

## 216

### **Suitability of Chemcatcher® passive samplers for the comprehensive screening of micropollutants in rivers**

C. Moschet, Eawag / Uchem; E. Vermeirssen, Eawag / Dept of Environmental Toxicology; H. Singer, Eawag / Aquatic Research; S. Christian, Eawag / Dep of Environmental Chemistry; J. Hollender, Eawag / Environmental Chemistry  
The goal of our study was to determine the suitability of passive sampling for a comprehensive screening of a very large number of polar to semi-polar micropollutants that are occurring in streams and rivers. To test this, a field study was carried out where 45 Chemcatcher® passive samplers were deployed, for two week periods, in five agriculturally and urban influenced Swiss rivers from March to July 2012. During the same time periods, two-week time-proportional composite water samples were taken for comparison. The investigated 322 substances – pesticides, pharmaceuticals, industrial chemicals and their transformation products with diverse physico-chemical properties (logKow -3 to 5, neutral, anionic, cationic, and zwitterionic species) – were analyzed by liquid-chromatography high-resolution tandem mass spectrometry. Results showed that Chemcatcher® passive samplers are perfectly suited for the qualitative screening of polar micropollutants. The number of detected substances was similar for both sampling methods (204 for passive samples vs. 207 for composite water samples), limits of quantification were comparable (median: 1.3 ng/L vs. 1.6 ng/L), and the handling of Chemcatchers® in the field and laboratory is fast and easy. The fact that so many different substances accumulate on the sampler also opens the door for a comprehensive screening for suspects or unknowns. In-situ calibrated sampling rates (field Rs) could be determined for 88 compounds, *i.e.* where a good regression was obtained between water concentration vs. sampled mass on passive sampler disk. It could be clearly shown that substances with moderately fluctuating river concentrations such as pharmaceuticals showed better correlations than substances with highly fluctuating concentrations such as pesticides (R-squared > 0.75 for 93% and 60% of the investigated substances, respectively). It was observed that ionic species had significantly lower field Rs than neutral species. However, a correlation between determined field Rs and hydrophobicity (logDow) could only predict Rs with large uncertainties. We conclude that substances with relatively constant river concentrations can be quantified accurately in the field by passive sampling. To do so, substance-specific Rs for these compounds need to be determined. For that purpose, in-situ calibration is a very robust method and the determined Rs can be used in future monitoring studies in rivers with similar environmental conditions.

## 217

### **Calibration and application of Polar Organic Chemical Integrative Samplers (POCIS) for monitoring sulfonamides and quinolones**

R. Baena-Nogueras, University of Cadiz / Physical Chemistry; T. Sultana, Trent University / Environmental and Resource Studies; C. Metcalfe, Trent University; E. Gonzalez-Mazo, University of Cadiz / Physical Chemistry; P. Lara-Martin, University of Cadiz (Spain)

Nowadays there is a growing concern regarding the occurrence and fate of trace amounts of pharmaceutically active compounds (PhACs) and endocrine disrupting compounds (EDCs) in aquatic environments. Commercial available POCIS are very valuable tools for long-term monitoring of these chemicals in water bodies. Our research group has already calibrated the use of these devices for a wide range of emerging contaminants (*e.g.*, antiinflammatories, beta-blockers) in freshwater settings, although there is still limited information (*i.e.*, determination of uptake kinetics) for many chemicals. In this study we have calibrated commercially available POCIS devices for 18 antibiotics (10 sulfonamides, 7 quinolones and 1

aminocoumarin antibiotic) in freshwater at two different temperatures (16 and 25°C). Uptake rates (*Rs*) are reported here for the first time, being between 0.201 and 1.541 L d<sup>-1</sup> for selected PhACs. Additionally, POCIS were spiked using different beta-blockers (sotalol-d<sub>6</sub>, propranolol-d<sub>7</sub>, metoprolol-d<sub>6</sub>, atenolol-d<sub>7</sub>) to evaluate their suitability as performance reference compounds (PRC). Several desorption experiments were carried out in the laboratory, resulting on metoprolol-d<sub>6</sub> being selected as a PRC to estimate time-weighted average (TWA) concentrations (0.04-2636 ng L<sup>-1</sup>) for PhACs and EDCs in Presqu'île Bay (Canada), where validation-field deployment was carried out. Data from this field sampling were used to conduct a preliminary environmental risk assessment in the area, showing that dissolved concentrations of ibuprofen may be high enough to induce chronic effects in freshwater organisms.

## 218

### **Contribution of passive sampling to an improved knowledge of the impact of pesticide uses in the head of river basin: example of the POCIS for moderately polar pesticides**

R. Guibal, University of Limoges / Research Group on Water Soil and Environment GRESE EA; S. Lissalde, Université de Limoges / Groupement de recherche eau sol environnement; A. Charriau, Laboratoire GRESE, Université de Limoges; R. Buzier, P. fondaneche, Université de Limoges / Groupement de recherche eau sol environnement; K. CLeries, Université de Limoges; g. poulier, Irstea / Unité de recherche REBX; N. Mazzella, Irstea; G. Guibaud, Université de Limoges / Groupement de recherche eau sol environnement

Facing difficulties in interpreting data from punctual samples collected only 4 to 6 times a year, a continuous monitoring by passive sampling has been performed (Polar Organic Chemical Integrative Sampler, POCIS). This work aimed at investigating the contribution of this sampling strategy for an improved knowledge of the impact of pesticide uses in an agricultural area. Pesticide contamination in the upstream part of the Auvézère (Limousin, France) was continuously monitored thanks to POCIS during 3 years (01/2012 to 12/2014). POCIS were deployed during 14 days and analysed for 35 target moderately polar pesticides and 9 metabolites. The monitoring was performed on the main stream (Auvézère River, Strahler stream order = 3) and one of its tributary (Arnac River, Strahler stream order = 2). A low contamination was noted in the main stream, while higher pesticide concentrations were measured in the Arnac River. This can be linked to the land cover, stream flows (with a lower dilution effect in the tributary) and stream typology (with the presence of numerous wetlands and small secondary tributaries). Owing to a POCIS continuous monitoring: - Periods at higher-risk of pesticide contamination could be identified. Fluxes increase during 2 periods: in spring and at the beginning of autumn, probably due to agricultural practices in the river basin. - The evolution of pesticide transfer to the aquatic system, in terms of both quality and quantities, was observed. Indeed, year 2013 was characterized by humid and cool weather conditions, which increased crop illnesses and also pesticide transfer to the aquatic system. - A peak contamination of atrazine (forbidden use in France for 10 years) was detected in June 2013 followed by a decreasing trend. Finally, the use of a high resolution time of flight mass spectrometer allow identifying non-target substances in some POCIS extracts (for instance isoxaben in Arnac River in summer 2014). Even if passive sampling only targets a part of the pesticides used in the river basin, it is a useful tool for the monitoring of contamination trends (from agricultural and non-agricultural sources) and the impact of environmental conditions on pesticide transfer. In extensive agricultural areas and head of river basin, small streams are abundant (Strahler stream order ≤ 2) and have a higher risk of being contaminated. However, the main stream (Strahler stream order = 3) is less prone to contamination, mainly because of dilution effects.

### **Critical micelle concentrations for different surfactants measured with polyacrylate-coated SPME fibres**

J. Hafitka, University of Utrecht / Institute for Risk Assessment Sciences; P. Scherpenisse, Utrecht University; G. Oetter, BASF; G. Hodges, Unilever Research / Safety and Environmental Assurance Centre; J.L. Hermens, Utrecht University / Institute for Risk Assessment Sciences

The measurement of physicochemical properties of neutral organic substances is important to predict partitioning or adsorption to environmental phases of interest. However, surface-active substances are amphiphilic molecules with both a hydrophobic alkyl chain and a hydrophilic head group. The amphiphilic nature of surfactants drives the formation of micelles at the critical micelle concentration (CMC). The CMC value is usually determined by measurement of electrical conductivity or surface tension. The CMC value can also be determined directly by the measurement of surfactant monomer concentrations using solid-phase microextraction (SPME) fibres. Because only freely dissolved concentrations of surfactant monomers are measured, the CMC is derived when the concentrations in the fibre reach a plateau in the fibre-water sorption isotherms. In this study, the determination of CMC for a wide selection of surfactants is evaluated with SPME fibres. The selected compounds covered non-ionic, anionic, cationic, and amphoteric surfactants from different compound classes. The CMC values for all surfactants were derived when the concentrations in the fibre became constant. The determined CMC values were in close agreement to the values reported in literature. In the linear phase of the fibre-water sorption isotherm, the slope of the

curve provided additional information on the sorption process to the fibre. For neutral surfactants, the fibre-water sorption isotherms showed linear partitioning to the fibre. However, the fibre-water sorption isotherms for anionic surfactants showed non-linear distribution to the fibre, probably because of sorption of ion-pairs to the fibre coating. Cationic surfactants also showed non-linear distribution to the fibre, because these compounds can specifically sorb to carboxylic acid groups that are present on the polyacrylate fibre surface. Surprisingly, amphoteric surfactants showed linear distribution to the fibre which was explained by a charge screening effect. The SPME fibre method has been shown to be applicable for the determination of CMC for surfactants from different compound groups. Furthermore, advantages of the SPME method are that differences in pH and ionic strength are taken into account and phase separation is not required, because freely dissolved concentrations are directly determined by the SPME fibres.

## Monitoring and modelling-based approaches for identification and prioritisation of hazardous emerging pollutants in European freshwater resources (I)

220

### Second review of the Priority Substances list under the Water Framework Directive

R.N. N. Carvalho, European Commission - Joint Research Centre / Institute for Environment and Sustainability; L. Ceriani, European Commission DG Joint Research Centre / Institute for Environment and Sustainability IES; A. Ippolito, EFSA - European Food Safety Authority / Institute for Environment and Sustainability IES; D. Marinov, JRC, EC / Institute for Environment and Sustainability; N. Adibi, Cd2e - Plateforme avniR / Institute for Environment and Sustainability; T. Lettieri, European Commission - Joint Research Centre / Institute for Environment and Sustainability

The European Water Framework Directive (WFD) currently lists 45 Priority Substances (PS), 21 of each classified as Priority Hazardous Substances (PHS), which have been selected amongst those which present a significant risk to or via the aquatic environment. The substances on this list should not exceed the respective environmental quality standard (EQS), i.e. a concentration that is considered safe to aquatic organisms or to humans via the aquatic environment. Under Article 16 (4) of the WFD, later amended by Directive 2013/39/EU, the Commission is required to review the list of PS at least every six years. The second review of the PS list has started in 2013 and will evaluate substances suspected of posing a risk to the environment following a dual approach i.e. a monitoring- and a modelling-based exercises. The monitoring-based exercise takes advantage of the available monitoring data gathered in Europe under different official monitoring programmes or research projects. Substances with sufficient monitoring data from a representative number of European countries are evaluated in terms of the Spatial, Temporal and Extent of exceedance (STE approach) of the Predicted No Effect Concentration (PNEC) of that substance. By contrast, the majority of substances in the initial list do not have sufficient monitoring data and therefore it is more difficult to estimate the exposure and the risks to the environment. Therefore a modelling-based exercise is run by first screening the substances for the fulfillment of several exposure and hazard criteria and secondly, a modelling-based risk assessment is done for relevant compartments and receptors. The estimation of predicted environmental concentration (PEC) and PNEC makes use of available information in the literature regarding the tonnage, use pattern, fate and effects of each substance, while in the absence of such information, different models are used to fill the knowledge gaps. Finally, the substances are ranked for prioritisation based on the highest of the calculated risk quotients (PEC/PNEC). The prioritization exercise is presented and illustrated with a few case studies.

221

### A proposal for an chemical assessment concept for the protection of raw water resources under REACH

M. Neumann, Federal Environment Agency (UBA) / Section IV Chemicals; M.A. Schwarz, FoBiG GmbH; D. Sättler, Federal Environment Agency UBA / IV Chemicals; J. Oltmanns, FoBiG GmbH; L. Vierke, Federal Environment Agency / Section IV Chemicals; F. Kalberlah, FoBiG GmbH

Chemical substances and their uses that fall within the scope of the REACH Regulation (1907/2006 EG) have to be registered at ECHA in Helsinki. Registrants are requested to ensure a high level of protection of human health and the environment. By doing so, industry guarantees the safe use of chemicals throughout the whole life cycle. Raw water resources for the production of drinking water need a high level of protection. In Europe drinking water is obtained mainly from groundwater, reservoirs or river bank filtration. If these environmental compartments are exposed to hazardous chemicals a contamination of drinking water is possible. In the last decade the fate and behaviour of polar substances has been investigated both scientifically and from a regulatory perspective. The finding is that their intrinsic hazard potential is maximised if they are at the same time persistent in the environment and mobile in the water cycle. Once emitted, these substances remain in the aquatic environment and the contamination is irreparable. If in addition they also fulfil the properties of being toxic emissions into water

resources should be avoided during the production and downstream use of the substances. Here we present a proposal for an assessment concept of persistent, mobile and toxic chemicals (PMT substances). We adopted the criteria for the identification of persistent substances directly from the Annex XIII of the REACH regulation. In Contrast we developed the M criteria with an extensive modelling approach using the software ECETOC-Targeted Risk Assessment (TRA, Version 3.0). We propose to identify a persistent substance as being also mobile if the water solubility is  $> 150 \mu\text{g/L}$  and the  $\log K_{oc}$  is  $< 4.5$ . The T criteria is fulfilled among other criteria if the minimum DNEL is  $< 9 \mu\text{g/kg} \times \text{d}$ . We applied the PMT assessment concept already to 93 REACH-registered chemicals and confirmed for 14 of them PMT-properties. A monitoring data review confirmed the presents of some of the PMT substances which is an initial validation of the PMT assessment concept. Within this research study a proposal for a practical guide was published. This guide may be used by registrants to assess whether a substance cause a concern for raw water. *Acknowledgment This study was contracted as project No. 371265416 for Environmental Research of the Federal Ministry for the Environment, Nature Conservation, Building and Nuclear Safety in Germany, in 2012 to 2014*

222

### Early identification of organic chemicals with a potential for long-term environmental contamination

M. Scheringer, ETH Zuerich; G. Stieger, ETH Zurich / Institute for Chemical and Bioengineering; J. Hollender, A.C. Chiaia-Hernandez, Eawag / Environmental Chemistry; T.D. Bucheli, Agroscope ART / Analytical Chemistry Natural Resources Environmental Protection in Agriculture; A. Keller, Agroscope ART; D. Wächter, NABO Swiss Soil Monitoring Network; K. Hungerbühler, ETH Zurich

There are several thousands of organic chemicals on the market and it is a challenging task to identify those with a potential for long-term environmental contamination. Chemical-intensive economies repeatedly cause contaminations of the environment that may remain undetected for years. A point in case is perfluorinated alkyl substances (PFASs), which have been used since the 1970s but were detected in the environment only after 2000. Because analytical campaigns and monitoring programs can cover only a selection of chemicals, strategies for identifying priority chemicals for analytical measurements are needed. Here we present a procedure that starts from an extensive computer-based screening of chemicals that may have a potential for long-term environmental contamination. This first step is complemented with field sampling of representative soils and sediments and application of analytical methods for identifying organic substances with logarithmic octanol-water partition coefficients ( $\log K_{ow}$ ) between 1 and 8. This procedure is applied to chemicals on the Swiss market; here we report mainly results from the first step. Relevant chemicals were extracted from Swiss customs statistics and product registers. This led to 17'409 individual chemicals. For 8953 (49%) of these, it was possible to retrieve their physicochemical properties and degradation half-lives. 2247 of these substances are halogenated and were selected for further investigation because halogenation facilitates analytical detection (characteristic isotopic patterns). The environmental partitioning of these chemicals was characterized with a multimedia fate model for Switzerland; chemicals with 90% or more in soil or sediment were identified (469 substances). This group includes a wide range of fluorinated, chlorinated and brominated aromatic and aliphatic substances, often with highly branched substituents, ether and tertiary amine groups, trifluoromethyl groups, phosphate ester groups etc. In the second step of the procedure, an analytical screening based on extraction of soil and sediment samples by pressurized liquid extraction and clean-up by liquid-liquid partitioning is performed and followed by liquid chromatography coupled to high-resolution mass spectrometry with electrospray ionization. Suspect screening of exact masses of chemicals possibly covered by this analytical method is performed and several contaminants have already been identified and confirmed by reference standards.

### Novel toxic pressure assessment for data poor substances by means of ecotoxicological concern level estimation

L. Posthuma, RIVM / Centre for Sustainability Environment and Health; K. Kramer, Mermayde; D. van de Meent, RIVM / DMG; I. Ottenbros, Utrecht University; D. De Zwart, RIVM / Centre for Sustainability Environment and Health

This presentation considers the challenging risk assessment of data-poor next to data-rich substances, describing and exploring an innovative, distributions-based ecotoxicity assessment approach for the former. Within the EU FP7 project SOLUTIONS, a solution-focused approach has been designed to address the spatio-temporal variability of contaminant mixture risks of current as well as future emissions. In a modeling-measuring combination, innovative approaches will be designed and evaluated for risk and impact assessment. This presentation focuses on risk modeling of mixtures of data rich and data poor substances together. Classically, toxic pressures for data rich compounds (a low fraction of all compounds) are derived using Species Sensitivity Distributions (SSDs), based on compound-specific ecotoxicity data. Addressing the challenge of looking at all the other compounds (the big fraction of compounds), we develop and test a novel distribution-based method, to evaluate the (net mixture) risks of data poor substances. The novel method was inspired by the concept of Threshold of Toxicological Concern (TTC) assessment. The method is applied, starting from

Danube-catchment emission data. When validated against (SOLUTIONS) effect data, the method may have implications for chemical footprint assessments, which in turn relate to (planetary) boundary definition and sustainable use of chemicals.

#### **An innovative integrated system of models and databases in support to the prioritisation of emerging contaminants on a European scale**

J. van Gils, DELTARES; D. van de Meent, RIVM / DMG; I.T. Cousins, Stockholm University / Department of Environmental Science and Analytical Chemistry ACES; D. Georgieva, Laboratory of Mathematical Chemistry / Laboratory of Mathematical Chemistry; A. Kortenkamp, Brunel University; D. De Zwart, RIVM / Centre for Sustainability Environment and Health; C. Lindim, ITM Department of Applied Environmental Science; S. Loos, DELTARES

Emerging pollutants may be posing a significant ecological and human health risk through their presence in water bodies. We do not know enough of them however, to assess and manage this risk. The EU FP7 project SOLUTIONS addresses this issue. SOLUTIONS combines monitoring and modelling-based approaches towards the prioritisation of emerging contaminants. This paper discusses the relevant modelling tools. The specific value of modelling tools is that, after a successful validation for well-studied substances and data-rich basins, the models allow extrapolations to “new” substances and other basins for which data are lacking. The SOLUTIONS integrated model system consists of four interlinked components. The risk modelling component follows a common tiered framework for human and ecological risk assessment. Specific ecotoxicological risk assessment will address mixtures effects on aquatic ecosystems. The risk modelling is driven by integrated components for emission and fate & transport modelling, supplemented by a component providing new methods for the prediction of partitioning, transformation and toxicity of emerging compounds. The modelling is spatially and temporally explicit and driven by detailed hydrology modelling. The fate & transport component provides mechanistic process-based modelling of a wide range of substances, including polar and ionic organic substances. The emission modelling component builds on collected and estimated market and use volumes for chemicals by combining data from existing registration frameworks, together with information on specific uses and releases of chemicals. The model framework relies on external data specifying the morphology, hydrology, geology and relevant socio-economic aspects on a European scale. The implementation of the model framework is planned over a five year period (2013-2018). The work so far has focused on (1) creating a flexible spatial schematisation, (2) making available the necessary hydrology forcing (water fluxes carrying emerging contaminants with them), (3) modelling particle fluxes (carriers of emerging contaminants) and (4) implementing first versions of the various submodels. The results obtained so far demonstrate the successful implementation of the integrated set of models and databases. We are well under way towards an important milestone, being the first model evaluation for around 300 chemicals using the 3rd Joint Danube Survey field data.

#### **Estimating the major sources of PFOS and PFOA to the Danube River catchment**

C. Lindim, ITM Department of Applied Environmental Science; I.T. Cousins, Stockholm University / Department of Environmental Science and Analytical Chemistry ACES; J. van Gils, DELTARES

Among perfluoroalkyl substances, perfluorooctanoate (PFOA) and perfluorooctanesulfonate (PFOS) are of special concern because they are persistent, bioaccumulative, toxic and globally distributed in the environment. The aquatic compartment is the main sink and transport media for these compounds. However there is no consensus regarding the dominant sources of PFOS and PFOA impacting aquatic ecosystems. While emissions from WWTPs are reportedly a major source, strong correlations were also found between population and PFOS and PFOA levels in water regardless of effluent treatment coverage or efficiency. In this work we use the Danube basin as case study to investigate dominant emission sources contributing to riverine loads of PFOS and PFOA. We test three hypothesis: 1. Human population alone can explain PFOS and PFOA levels in river water. 2. Human population combined with WWTP treatment can explain PFOS and PFOA levels in river water. 3. Human population combined with consumer wealth can explain PFOS and PFOA levels in river water. A fate and transport model with subcatchment resolution was used to simulate PFOS and PFOA concentrations in the river Danube for the three different emission hypotheses tested. Model predictions were then compared with measured values. It was found that PFOS emissions based only on population (hypothesis 1) or on population plus WWTP data (hypothesis 2) are not able to explain levels and spatial distribution of PFOS measured in the Danube River. For PFOS, we found that emissions have spatial variations that can be reasonably well attributed to GDP differences. PFOS emissions are therefore associated with consumption and disposal of PFOS-containing products. For PFOA our results were inconclusive about the dominant contributions to emissions but they point out that where industrial contributions exist or once existed their regional importance largely surpasses contributions from humans *per se* even for locations with high populations.

#### **Are current approaches suitable to describe the environmental fate of nanopesticides?**

M. Kah, University of Vienna / Department of Environmental Geosciences; A. Weniger, University of Vienna; T. Hofmann, University of Vienna / Department of Environmental Geosciences

Research into nanotechnology applications for use in agriculture has become increasingly popular over the past decade. We first carried out a comprehensive literature review [1] with the objectives (i) to explore potential applications of nanotechnology within the pesticide formulation sector, (ii) to identify possible impacts on environmental fate, and (iii) to analyse the suitability of current exposure assessment procedures to account for their novel properties. Investigations into the environmental fate of nanopesticides remain scarce, and current approaches, which considers the soluble portion of organic substances to be of importance, may not adequately describe the nano behaviour that some nanopesticides will exhibit after application [2]. The latest trends in research [3] indicate that polymer-based nanoformulations seem to have the greatest potential for further development. Experiments were thus carried out on a series of polymer-based nanopesticides representing a range of properties. We considered two active ingredients covering extreme scenario for sorption and degradation characteristics and polymer nanocarriers exhibiting a range of colloidal characteristics (e.g., size distribution, electrostatic vs steric stabilization). The application of regulatory protocols to determine sorption and degradation in two agricultural soils (OECD guidelines) confirmed that a nanoformulation can affect the fate of an active ingredient [3]. Conclusions about exposure assessment outcomes should be made cautiously as currently used protocols were designed to assess the fate of solutes, and may not adequately described the “nano” behaviour of active ingredients associated with nanocarriers. Results from additional tests looking into release profiles and transport behaviour in porous media, serve as a useful basis to discuss the (in)adequacy of current approaches, and make recommendations for a more robust regulatory evaluation of environmental risks. #### **Aggregation of engineered nanoparticles in the natural environment: is the process reversible?**

S.R. Thompson, Depment of Physics Environment Department; J. Yuan, University of York / Phycis; A. Boxall, University of York / Environment Department Engineered nanoparticles (ENPs) are increasingly being used in a wide range of product classes. The increase in use of ENPs will inevitably lead to increased emissions to the natural environment so it is important to develop an understanding of the environmental fate, behaviour and effects of ENPs. Following release to the environment, ENPs can aggregate depending on the environmental conditions; consequently aggregation is one of the key processes that is included in environmental exposure modelling exercises. However, in these exercises, it is typically assumed that aggregation proceeds in one direction and that the process is non-reversible. This is an important assumption, because usually the primary, unaggregated particles will have significantly greater ecotoxicity compared to the aggregated systems. This study examines the validity of this assumption, by exploring whether changes in environmental parameters including pH, temperature, and kinetic environment could result in disaggregation of ENP aggregates. Results suggest that environmentally relevant changes in environmental parameters can result in disaggregation of selected ENPs. Existing exposure modelling approaches may therefore need adapting to account for this reversibility of the process.

#### **Fate and effects of silver nanoparticles in aquatic indoor microcosms**

C. Wasmuth, Fraunhofer IME - Institute for Molecular Biology and Applied Ecology; C. Schaefers, Fraunhofer-Institut / Ecotoxicology; H. Ruedel, Fraunhofer IME - Institute for Molecular Biology and Applied Ecology / Environmental Monitoring; T. Klawonn, Fraunhofer IME Institute for Molecular Biology and Applied Ecology

In this study we examine fate and possible ecotoxicological effects of both, silver nanoparticles (AgNPs) and Ag<sup>+</sup> released by AgNPs, in aquatic indoor microcosms. The intended study period is 200 days. Each unit has a volume of 1 m<sup>3</sup> and contains natural sediment (0.25 m<sup>3</sup>), surface water (0.75 m<sup>3</sup>), zooplankton and phytoplankton. AgNPs with a mean diameter of 20 nm are applied to the microcosms at four different target concentrations. A continuous exposure is ensured by periodic additions of the test compound. In parallel, four control microcosms are used. The setup allows testing the toxicity of AgNPs and Ag<sup>+</sup> towards zooplankton and phytoplankton. In the water phase concentrations of different silver fractions are determined: total silver (unfiltered), dissolved silver (after filtration through a < 0.2 µm membrane filter) and ionic silver. The ionic silver is separated by centrifugal filtration. Analyses are performed by validated ICP-MS methods. Quantified silver concentrations (total, < 0.2 µm, ionic silver)

will be related to possibly observed toxicity effects. Delayed fluorescence measurements are applied for determinations of the chlorophyll content in the water phase (as measure for the phytoplankton content). Evaluation of the first study phase shows that maximum concentration of ionic silver in the water phase were clearly lower than the total silver concentration (e.g., by a factor of about ten for the highest exposure level). First results of delayed fluorescence measurements indicate an increased phytoplankton growth in microcosms and a degradation of zooplankton. *Acknowledgement* - The authors thank Elisabeth Meyer, Martin Eickhoff, Klaus Peter Ebke, László Dören, Rainer Peters, Diana Wilhelm, Dirk Hansknecht, Kevin Ladage and Boris Meisterjahn.

#### **The fate of nanomaterials at the river/ocean frontier using large mesocosms: the case story of silver nanoparticles**

E. Pelletier, University of Quebec, Rimouski / ISMERUQAR; G. Bardaxiglou, University of Quebec at Rimouski / ISMERUQAR; M. Barthe, Université du Québec Rimouski; P.G. Campbell, Université du Québec, INRS / INRS Eau Terre Environnement; I. Desbiens, University of Quebec, Rimouski / ISMER; C. Fortin, University of Quebec / Centre Eau Terre Environnement; J. Gagné, Université du Québec Rimouski; C. Gagnon, Environnement Canada / Centre SaintLaurent; J. Gagnon, University of Quebec in Rimouski; C. Guilleux, Université du Québec INRS; K. Lemarchand, Université du Québec Rimouski; M. Millour, Université du Québec Rimouski; C. Roleau, Peches et Océans Canada; G. Triffault-Bouchet, Centre d'expertise en analyse environnementale du Québec / Écotoxicologie et évaluation du risque

In this large project supported by NSERC (Natural Sciences and Engineering Research Council of Canada), we studied pathways taken by engineered silver nanomaterials from their sources to various environmental compartments (fresh and marine waters, suspended particulate matter, sediment and biota). The originality of the project resides in using five large mesocosms (3000-L each) to mimic real field conditions when riverine waters are mixing with coastal waters. The experimental flow-through setup allowed for the formation of a strong halocline and thermocline between the incoming freshwater on the top layer and the incoming unfiltered natural seawater layer (29 PSU) at bottom. The freshwater layer contained engineered silver nanoparticles (ESN, 20 nm mean diameter, citrate coated), dissolved and particulate organic matter (POM), suspended unicellular algae and clay. The unfiltered seawater layer contained pelagic microorganisms and several macro-benthic species. Each mesocosm was sampled at different depths for physical, chemical and biological monitoring over a period of 6 weeks. The turnover time for the water mass in each mesocosm was about 36 h, allowing enough time for some slow reactions such as adsorption/desorption equilibrium on particulate matter, auto- and hetero-aggregation and sedimentation to occur. The percentage of dialyzable silver (100-500 Da) in the freshwater layer increased from about 5 to 15% in the first three weeks, indicating a slow dissolution of ESN and a possible trapping of dissolved Ag in the fresh water layer. Dissolution was shown to increase with increasing salinity. The main results indicate a strong retention of ESN at the halocline layer with a very limited transport of settling particles through the halocline to the seawater layer. Macro-benthic organisms (blue mussels, clams, amphipods, sea urchins and winkles) held in the seawater layer for weeks did not accumulate significant amounts of silver. However, blue mussels exposed to the mesocosm effluent (mixed waters with ESN) showed a strong bioaccumulation of silver, confirming the bioavailability of ESN to marine species in contact with the mixing layer. ESN hetero-aggregated with clay and POM represent underestimated risks for marine organisms (mainly larvae and juveniles of marine invertebrates and fish) swimming and feeding in the halocline layer in coastal waters.

230

#### **A comparative study of the influence of water chemistry (humic acid, and hardness) on silver nanomaterial toxicity to model organisms *Lumbriculus variegatus* and *Danio rerio* larvae.**

C.C. Liddle, F.G. Lara, H.J. Jonston, T.B. Henry, T.F. Fernandes, Heriot-Watt University / School of Life Sciences

Given the widespread use of silver nanomaterials (Ag NM), their release, whether accidental or intentional, into the environment is inevitable. At this point, Ag NPs threat to freshwater ecosystems is unclear. Current research shows NM fate and toxicity is affected by water chemistry, the presence of organic matter, sediments and other possible influences, such as hydraulics. As such, there is a need to further the understanding of NMs' fate and toxicity in the aquatic environment. This research investigated abiotic conditions which may affect Ag NM toxicity in freshwater environments; in an attempt to identify what water chemistry may lead to higher hazard, using the Californian blackworm, *Lumbriculus variegatus* and Zebrafish larvae, *D. rerio*, as model organisms. Survival, locomotive behaviour (black worms), heartbeat (larvae), and NM physicochemical characteristics were assessed for Ag NM (polyvinylpyrrolidone (PVP) coated; nominal size 30-50nm) and aqueous silver in static synthetic freshwaters of different chemistries. Results indicated, aqueous silver and Ag NM caused dose dependant mortality in both species, within synthetic hard water. Exposure of aqueous silver and Ag NM to *L. variegatus* and *D. rerio* larvae had dose response LC50s of  $0.27 \pm 0.01$ ,  $0.35 \pm 0.04$  and  $38 \pm 0.74$ ,  $86.03 \pm 14.74$  ( $\mu\text{mol Ag L}^{-1}$ ; 95%CI), respectively. Analysis of dose responses indicated a significant difference of Ag NM dose response in soft water for *D. rerio*, relative to hard water; no significance was indicated for *L. variegatus*.

Suwannee river humic acid (0-50mg/l) reduced the toxicity of  $55.62 \mu\text{mol Ag L}^{-1}$  of waterborne NMs to *L. variegatus*. For *D. rerio* a  $10 \text{ mg L}^{-1}$  of humic acid did not significantly reduce the toxicity of Ag NM in hard water. Analysis of dose responses, between species, indicated Ag NMs are more toxic to *L. variegatus* in hard water, no differences between species were found between aqueous silver in hard water & Ag NM exposure in soft water. It is evident that waterborne PVP coated Ag NMs are moderately toxic to *L. variegatus* and *D. rerio* larvae in simple water matrices. Results indicate that Ag NM toxicity is influenced by the composition of the medium, and therefore environmental fate processes are likely to alter waterborne Ag NM toxicity. However, the mode of action and influence of these changes appear to be *phyla* specific, indicating the importance of testing effects on different taxonomic groups.

231

#### **Physicochemical properties of AgNP influencing bioaccumulation and toxicity in *Lumbricus rubellus***

S. Makama, Alterra Wageningen University and Research Centre / Toxicology/Animal Ecology; A. Undas, RIKILT Inst. Of Food Safety WUR / Business Unit Contaminants Toxins; J. Piella, Institut Català de Nanociència i Nanotecnologia (ICN2); R. Peters, RIKILT / Contaminants; V. Puentes, Institut Català de Nanociència i Nanotecnologia (ICN2); N.W. van den Brink, Wageningen University / Dept of Toxicology

In this study, our purpose was to investigate the effect of size, surface coating and associated charge of silver nanoparticles (Ag NPs) on the bioaccumulation in and toxicity to the red earthworm *Lumbricus rubellus*. Silver nanoparticles were synthesized to produce three sizes: 20, 35 and 50 nm. These were coated with either chitosan (CHIT), bovine serum albumin (BSA), or polyvinylpyrrolidone-55 (PVP-55) to produce positive, negative and neutral particles respectively. During a 28-day sub-chronic reproduction toxicity test, earthworms were exposed to varying concentrations of the nine (9) AgNPs in wet-spiked soil. To compare the bioaccumulation of ionic Ag, the earthworms were similarly exposed to  $\text{AgNO}_3$  at concentrations insufficient to cause mortality. Reproduction was diminished at high concentrations of all NPs tested, with BSA-coated particles being the most toxic ( $\text{EC}_{50}$  for the 20 nm NPs was 66.8 mg Ag/kg soil, with < 60 mg Ag/kg soil already showing a decrease in the cocoon production). Thus, in terms of adverse effects observed with the tested AgNPs, BSA (negative) > PVP-55 (neutral) > Chitosan (positive). Total Ag tissue burden is expected to reflect a concentration-dependent accumulation in earthworms, with more Ag likely accumulating in tissues from  $\text{AgNO}_3$  treatment groups. Analyses of Ag speciation in earthworm tissues is underway and will be presented, with specific attention paid to whether quantified particulate or ionic burdens of the earthworms explain toxicity most. The present study provides further evidence of the influence of surface coating (charge) as well as size in driving bioaccumulation and toxicity.

#### **Delving into the planetary boundary concept and issues related to biodiversity and natural resources use in LCA (I)**

#### **Capturing the benefits of responsible forestry practices in LCA: focus on biodiversity**

V. Rossi, S. Humbert, Quantis; S. Gueye, U. Schenker, Nestle Research Center; L. Lundquist, N. Espinoza Orias, Nestlé; T. Lehesvirta, O. Koski, UPM; R. Taylor, Texas AM University / Trace Element Research Laboratory; P. Oliveira, UPM Companies and communities are increasingly adopting responsible sourcing practices in their supply chain. However, the benefits of using responsibly sourced products are still difficult to quantitatively capture in the context of life cycle assessment (LCA) in particular with regards to their benefits for biodiversity or ecosystem services. Nestlé, a company aiming at adopting responsible sourcing practices throughout its supply chain, UPM, one of their suppliers and a global leader in sustainable forest management practices, along with Quantis, a company expert in LCA, have developed an approach to quantify the ecological benefits of responsible forest management practices using environmental indicators typically used in LCA, including impact on ecosystem/ecosystem quality (in PDF.m2.y), land use (in m2.y), and GHG emissions. The aim was to build a solid methodology that can capture, within an LCA context, the relevant differences between conventional and responsible forestry practices for several case studies, of which semi-natural forest in Finland is presented. The study is for one cubic meter of wood, at mill gate, and encompasses the inputs for forestry management, activities on the logging site, logistics until the mill gate and the differences in energy inputs and outputs for heat recovered from wood residues in the mill. The use of the wood fibre based product and its end-of-life are not considered (considered identical for all types of wood sourcing). Carbon uptake and all GHG emissions are considered. The method for biodiversity accounts for four indicators, native tree species composition, deadwood volume and quality, protected valuable habitats, and forest structure, that are grouped into one indicator between 0 and 1. The results show that responsible practices have consistently lower impacts than conventional practices for all indicators, in Finland. For example, when quantified in PDF.m<sup>2</sup>.y, the impacts on Ecosystem/Ecosystems Quality for responsible forestry practices are about half of those for conventional practices. This method can objectively capture the benefits of biodiversity protection in wood fibre production. Companies can use it in

complex LCAs to consistently quantify impacts and benefits in supply chain. This method can be used to communicate externally about the benefits of biodiversity protection associated with responsible wood sourcing within an LCA context in a more robust way than what is done until now.

233

#### **Applicability of acoustic diversity to life cycle assessment of land use: a case study of oil palm production in South Sumatra**

K. Hayashi; V. Dhian, E. No-Last-Name, Indonesian Oil Palm Research Institute  
Recent publication of global characterization factors (CFs) for life cycle assessment (LCA) of land use has enabled the assessment of potential impacts of land use on biodiversity. However, biodiversity impact of agricultural management practices calculated using the CFs tends to be dependent only on crop yields and the necessity of establishing more refined CFs was pointed out. In conducting more refined biodiversity assessment, one of the crucial issues is the lack of data especially at the site-specific conditions. Therefore, another research direction is required, in which data collection is implemented within the methodology. A promising approach is the use of simple acoustic monitoring to assess biodiversity. The purpose of this study is to appraise applicability of acoustic diversity to LCA of direct land use impacts. In order to measure biodiversity in different land use (palm oil plantations and natural forests), we made sound recording at the fields and analyzed acoustic files. The Acoustic Complexity Index (ACI) was utilized for quantifying each sound file. The case study was carried out in South Sumatra. Four recording points were determined within and next to the Dawas plantation of the Indonesian Oil Palm Research Institute; two points in the plantation, one point in enclave forest, and one point in conservation forest. The results indicate that the ACI illustrates a state of recorded sounds produced by animals, rather than directly indicating the degree of biodiversity. Biodiversity can be explained as the behavior of the states. Therefore, biodiversity is described using scale parameters such as standard deviations rather than location parameters such as means. An implication of the results is that scale parameters can be used as a proxy for the quality of biodiversity, which is the vertical axis in the assessment framework for LCA of land use. Using rapid bioacoustics in LCA of land use is promising, because it can gather site-specific biodiversity data without using much time and cost, although there are limitations due to acoustics, i.e., the data are limited to sounds produced by animals when moving, communicating, and sensing their environment. The next step of this study is justification of methodology through the identification of animal species appeared in sound files.

234

#### **Nature conservation in Life Cycle Assessment - new method and case study with the palm oil industry**

J.H. Schmidt, 2.-0 LCA consultants

In agriculture and forestry, an important means for mitigating impacts on biodiversity and climate change is nature conservation. However, this is seldom included in life cycle assessment (LCA) and most LCA and footprint guidelines prescribe that off-setting shall be excluded. Obviously, there are good reasons for excluding off-setting in the guidelines, however in some cases the distance between the studied product system and a mitigation option (offset) is very short, and the industry managing the product system may be the (only) one who is able to implement the mitigation. This is the case for companies operating in countries where the frontier between product systems and high conservation value nature is moving. The purpose of this paper is to describe how the most recent research within indirect land use changes can be used to creating a cause-effect based method for quantifying the life cycle implications of nature conservation. The application of the method is demonstrated with a case study LCA of palm oil production at United Plantations Berhad in Malaysia and Indonesia. With their recent expansion of the plantation area into Central Kalimantan Indonesia, United Plantations has voluntarily set-aside more than 8000 hectares of high value conservation and high carbon stock land for permanent nature conservation. The study shows that nature conservation can significantly reduce the impacts on biodiversity and climate change. United Plantations Berhad is using LCA as one of the central tools for monitoring and reporting their environmental performance over time. Therefore, it is important to be able to include the effects of nature conservation together with other mitigation initiatives in their LCAs. The potential of mitigating impacts in biodiversity and climate change using nature conservation driven by industry is regarded as being large. Given the general strong emphasis on the implementation of Life Cycle Thinking in industry and policy making, the current scope of LCA and footprint guidelines may reflect a missed opportunity for creating incentives for securing nature conservation reserves in fast diminishing natural habitats. Therefore, it is recommended that nature conservation offsetting is included in LCA and footprint guidelines when the conservation is initiated/managed by companies operating in the frontiers of nature. Obviously, sound systems for avoiding greenwashing also need to be set-up.

235

#### **Land use impacts on biodiversity: Results from the consensus-building procedure sponsored by UNEP/SETAC's Life Cycle Initiative**

L. Milla i Canals, UNEP; O. Michelsen, NTNU / Industrial Ecology Programme; R.F. Teixeira, Biology; D.M. Souza, Swedish University of Agricultural Sciences; M. Curran, Institute of Environmental Engineering, ETH Zurich; A. Assumpcio,

IRTA

Environmental impacts of production and consumption are increasingly coming into the focus of companies and governments. Life Cycle Assessment (LCA) is one of the most important approaches to quantify environmental impacts of products from cradle to grave. Applied as a decision-making tool and/or as a support to policy development, it makes use of indicators to consider different environmental aspects over a system's life cycle. With increasing economic globalization, there has been a steadily growing need to create a worldwide consensus set of environmental indicators. The UNEP SETAC Life Cycle Initiative has successfully provided a platform for consensus finding in the area of environmental indicators in LCA. A flagship project has now been established by the Life Cycle Initiative intended to run a global process aiming at global guidance and consensus building on a limited number of environmental indicators, including indicators those for assessing impacts from land use (LU) interventions, such as land use change (LUC), on biodiversity. LU/LUC is one of the main drivers of biodiversity loss and degradation of a broad range of ecosystem services. Land competition is very likely to increase in the future and the task to halt biodiversity loss became one of the top global priority issues. LCA has a decisive word to say because of its nature as an aggregator of direct and indirect impacts allows producers and policy-makers to assign responsibility for damages to biodiversity. However, despite substantial contributions to address biodiversity loss in LCA, no clear consensus exists yet on the use of (a) specific impact indicator(s). Given the importance of the environmental pressures on biodiversity and how much LCA can potentially contribute to conservation targets, it is imperative to align the LCA community around points of consensus, as well as point the way forward to better models that can service the community. In this presentation we establish the operational principles of the flagship project regarding biodiversity impacts from LU/LUC. We show results from two expert workshops where stakeholders agreed on the requisites of good biodiversity indicators. We also present results from a consistent review of current biodiversity impact assessment methodologies. We highlight some preliminary and expected results and deliverables before the end of the mandate of the taskforce in late 2015.

236

#### **Combining Species-Area Relationships and IUCN Vulnerability Indicators for Assessing Land Use Impacts on Biodiversity**

A. Abhishek, ETH Zurich / Environmental Engineering; S. Hellweg, ETH Zurich / Institute of Environmental Engineering

Global biodiversity is essential for ecosystem functioning but faces unprecedented extinction risks mainly from habitat loss caused by human land use. While the species-area relationship (SAR) models are widely used in ecological and conservation studies to predict species extinction resulting from habitat loss in terrestrial systems, its use within LCA has been limited. Earlier studies have used classic and matrix SAR models to estimate terrestrial biodiversity loss for different land use types within LCA. We propose to use Countryside SAR instead, which has recently been proven to perform better than both Matrix and classic SAR in predicting species extinction from habitat loss in a heterogeneous, human modified landscape. The damage to biodiversity is calculated in the units- absolute species loss due to land occupation and transformation for six land use types (annual crops, permanent crops, extensive forestry, intensive forestry, pasture and urban), and five taxa (plants, mammals, birds, amphibians, and reptiles) in 804 terrestrial ecoregions. The empirical data for model input parameters was collected through extensive literature review. Uncertainty is assessed using Monte Carlo simulations. While the SAR models account for ecosystem vulnerability, in this study we propose to additionally include species-specific vulnerability score (VS; giving higher weight to species near extinction), as an indicator for global extinction risk. The VS (scaled between 0 to 1) is a function of the geographic range of the species and the IUCN assigned threat level. Globally across all ecoregions, the CF values for a particular taxa and land use type ranged over six orders of magnitude. For a given taxa in an ecoregion, the CFs of different land use types varied by an order of magnitude. For a particular land use type in an ecoregion, the CFs differed by two orders of magnitude across the four taxa. Highest CFs were observed for land use in tropical ecoregions, followed by temperate and boreal areas. The results therefore show that the region where land use takes place is relatively more important than the land use type or taxa for determining the species loss. The VS-weighted countryside CFs give absolute instead of a relative measure for biodiversity loss in LCA and can be used by decision-makers to quantify the biodiversity footprint of products with complex supply chains and globally distributed land use flows.

#### **Large-scale monitoring of seasonal effects of Clothianidin dressed oilseed rape on pollinating Hymenopterans in Northern Germany: Project aims and project area**

F. Heimbach, A. Russ, Tier3 Solutions GmbH

To protect pollinating insects from challenges of Plant Protection Products (PPP)

and their possible adverse effects have to be assessed. The EFSA Guidance on Risk Assessment of PPPs on bees also suggests an exigency of risk assessment for honey bees at the landscape scale. In compliance with these regulations, Elado®, a commercial seed coating of Oilseed Rape (OSR) containing Clothianidin as active ingredient, was registered in the EU in 2006. The application of Clothianidin was suspended for two years in 2013 and is now subject to extensive re-examination. Therefore, the project "Large-scale Monitoring of Long-term Effects of Elado (10g Clothianidin & 2g Beta-Cyfluthrin/kg seed) Dressed Oilseed Rape on Pollinating Insects in Mecklenburg-Vorpommern, Germany" was initiated. This project aims to investigate possible side effects of Elado dressed OSR seeds on honey bee colonies, mason bees and bumble bees under actual agricultural conditions. The study was conducted in Mecklenburg-West Pomerania (Mecklenburg-Vorpommern) because of the suitable landscape characteristics and agronomic infrastructure. The agricultural fields in this area are well suited for the project as they represent the typical landscape characteristics and agronomic infrastructure of northern Germany. OSR is cultivated in large-scale of the arable land and Elado-treated OSR varieties are preferentially applied. The farms of this region operate under large commercial models and, thus, enable an efficient cooperation with a manageable number of farmers. Two circular Study Sites of approximately 65 km<sup>2</sup> each surround the investigated bee hives and provide in total nearly 1,800 ha of OSR crops (27 % of arable land). The project consists of four different pollinator studies performed by different institutions at the same time during OSR blossom: a honey bee, a mason bee and a bumble bee monitoring study, as well as a residue analysis of nectar and pollen from foraging honey bees. The monitoring studies will be presented and discussed in separate presentations. Clothianidin treated OSR did not cause any detrimental effects on the development of hives and brood of honey bees and bumble bees or the nesting activity and reproduction of mason bees neither during OSR blossom in spring nor thereafter until the end of the study. The pollen composition, infestation with diseases and parasite load was also not affected by the exposure to Clothianidin treated OSR in any of the investigated bee species.

### 238

#### **Large-scale field study of seasonal effects of clothianidin-dressed oilseed rape on honey bees (*Apis mellifera*) in Northern Germany**

D. Rolke, Institut für Bienenkunde Oberursel Polytechnische Gesellschaft; B. Grünwald, Goethe-Universität Frankfurt am Main / Institut für Bienenkunde; W. Blenau, University of Cologne / Zoological Institute

We investigated possible side effects of Elado-dressed oilseed rape (OSR) on various pollinating insects in a large-scale monitoring project in Mecklenburg-West Pomerania, Germany in 2014. In this region, OSR is usually cultivated at 25-33% of the arable land. The monitoring study with honey bees (*Apis mellifera*) was part of the project to assess possible effects of clothianidin on colony development, honey production, pollen foraging, and colony health. A control and a treatment site of approx. 65 km<sup>2</sup> each were selected. For each site, 6 study locations were selected and 8 honey bee hives were placed at each location. While 3 locations were directly adjacent to OSR fields in each site, 3 locations were situated 400 m apart from the nearest OSR field. Thus, 96 hives were exposed to fully flowering OSR crops (BBCH 63-65) on 22 April 2014. Possible effects of clothianidin treatment were investigated by monitoring the development of colony sizes and weights, the amount of honey harvested and the infection with various diseases and parasites. Collected pollen was sampled to determine the percentage of OSR pollen. In addition, residue analyses were performed for pollen, nectar and honey from each colony. After OSR blossom (21 May 2014), the hives were transferred to an extensively used area in Hesse, Germany for post exposure monitoring. There, the same parameters (except for residues) were assessed until end of September 2014. Total numbers of adult bees and brood cells showed typical fluctuations. The honey which was extracted at the end of the exposure phase, contained 62.0-83.5% OSR pollen. This identifies OSR as the major nectar and pollen source during exposure. No clothianidin residues were detected in samples from colonies of the control site. Clothianidin concentrations in samples from the treatment site were below the limit of quantification in nectar and pollen and  $1.4 \pm 0.5$  µg/kg in honey. Varroa infestation was low during most of the course of the study but increased at the end of the study. However, no significant differences were observed between hives from treatment and control sites. Honey bee colonies foraging in clothianidin-dressed OSR did not show any detrimental symptoms as compared to colonies foraging in clothianidin-free OSR. Development of colony strengths, brood success as well as honey yields and pathogen infections were unaffected during this field study.

### 239

#### **Large-scale field study of seasonal effects of Clothianidin dressed oilseed rape on bumble bees (*Bombus terrestris*) in Northern Germany**

G. Sterk, IPM Impact; B. Peters, Tier3 Solutions GmbH

In order to investigate possible long-term side effects of Elado dressed Oilseed Rape (OSR) on different pollinating insects, a large-scale monitoring project was initiated in 2014 in Mecklenburg-West Pomerania, Germany. In this region, OSR is usually cultivated at 25 - 33 % of the arable land. The monitoring study with large earth bumble bees (*Bombus terrestris*) was part of the project to assess possible short- and long term effects of Clothianidin on development, behaviour and reproduction. A control and a treatment site of approx. 65 km<sup>2</sup> each were selected and per site 6 study locations identified for the placement of bumble bee colonies.

While 3 study locations were placed directly adjacent to OSR fields in the control and treatment site, 3 study locations were placed 400 m apart from the nearest OSR field. At every location 3 multi-hives (containing 3 hives each which were used for regular assessments) and additionally 1 single hive (used for collection of pollen) were established. To achieve a high compatibility, every hive consisted of a mother queen from the same hibernation batch and 40 to 50 workers at roughly the same age. The effects of the Clothianidin treatment during the exposure phase were investigated twice a week by recording the weight of the hive and by estimation of the brood size (cm<sup>3</sup>) and the number of workers. In addition, pollen was sampled from returning bumble bee workers to determine the percentage of OSR pollen in the pollen loads and to quantify the residues of Clothianidin. At the end of OSR blossom, the hives were transported to a National Park. At the end of the life time of the colony, the hives were dissected and the new born queens, drones and remaining workers as well as the undeveloped brood cells counted. A very homogenous and constant development was observed for all bumble bee colonies. The number of new born queens was high. The amount of OSR pollen in the pollen loads of bumble bees was on average 44 %. No Clothianidin residues were quantified at the control site, whereas about 1.1 µg/kg were analysed at 3 out of 6 locations in the treatment site. At all other treatment locations, the concentration of Clothianidin residues was below the Limit of Quantification (LOQ = 1.0 µg/kg). In summary, Clothianidin treated OSR did not cause any detrimental effects on the development of the bumble bee colonies neither on growth of the hive nor on reproduction.

### 240

#### **Large-scale field study of seasonal effects of Clothianidin dressed oilseed rape on mason bees (*Osmia bicornis*) in Northern Germany**

B. Peters, Tier3 Solutions GmbH

In order to investigate possible long-term side effects of Elado dressed Oilseed Rape (OSR) on different pollinating insects, a large-scale monitoring project was initiated in 2014 in Mecklenburg-West Pomerania, Germany. In this region, OSR is usually cultivated at 25 - 33 % of the arable land. The monitoring study with red mason bees (*Osmia bicornis*) was part of the project to assess possible short- and long term effects of Clothianidin on nest building, reproduction and fertility. A control and a treatment site of approx. 65 km<sup>2</sup> each were selected and per site 6 study locations identified for the placement of mason bee cocoons and nesting facilities. At every location 3 nesting shelters were arranged in front of a hedge or forest. 8 nesting blocks (containing 200 nesting holes each) and 2 cardboard boxes with a total number of 1500 cocoons were placed into the shelters at each study location. While 3 study locations were placed directly adjacent to OSR fields in the control and treatment site, 3 study locations were placed 100 m apart from the nearest OSR field. The study started at the beginning of OSR full flowering (BBCH 63-65) with the placement of cocoons. Emergence of provided mason bees was checked and nest building activities were assessed by observing nesting females. Pollen was sampled from the active brood cells for residue and pollen composition analysis (Palynology). Different climatic conditions were recorded at each location. At the end of OSR blossom nesting shelters were closed and removed to a sheltered place to avoid further production of offspring. In autumn 2014 offspring cocoons were harvested to evaluate the reproductive output and parasitism. Thereafter cocoons were stored in a refrigerator at 4 °C. After wintering, the emerging success of mason bee offspring was investigated. Altogether, females produced on average 2.59 offspring at the control and 2.95 at the treatment site. The amount of OSR pollen in the brood cells of mason bees was on average 14 %. No Clothianidin residues were quantified at the control site, whereas about 1.4 µg/kg were analysed at 2 out of 6 locations in the Treatment Site. At all other treatment locations, the concentration of Clothianidin residues was below the Limit of Quantification (LOQ = 1.0 µg/kg). In summary, Clothianidin treated OSR did not cause any detrimental effects on the development of red mason bees, neither on the nest building activity and reproduction nor parasitism.

### 241

#### **A Field study using RFID (radiofrequency identification) to Monitor Effects on Homing Behaviour of Honeybees Foraging on Thiamethoxam Treated Oilseed Rape**

m. coulson, Syngenta; H. Thompson, Syngenta Ltd / Environmental Safety; N. Ruddle, Syngenta; S. Wilkins, Food and Environment Research Agency / Centre for Chemical Safety and Stewardship

The European Food Safety Agency (EFSA) required more data to understand the effects on honeybees following their exposure to thiamethoxam treated oilseed rape. A 2012 study by Henry *et al* used the radiofrequency identification (RFID) technique to assess effects following a simulated exposure to thiamethoxam. The dosing in the study is, however, at a concentration approximately 30x higher than that which occurs in thiamethoxam treated oilseed rape nectar and pollen. Similar work by Schneider *et al*, with the neonicotinoids imidacloprid and clothianidin, at field relevant concentrations, concluded that there were no adverse effects for either substance. In this study, similar methodology was employed but with exposure of the bees to a thiamethoxam treated oilseed rape crop. One thiamethoxam treated field and two untreated control fields, all approximately 2 ha, were used in the study and were located in Lincolnshire, UK. All field sites were separated by at least 2km and were chosen so as not to be close to bee attractive crops flowering at the same time. There were twelve honeybee colonies per treatment group, four located at the field edge, four at approximately 500m from the field site and four at 1 km from the

field site. Prior to the start of the study worker honeybee brood were collected from colonies and returned to an incubator in the laboratory where the adult bees were allowed to emerge. The emerged bees were 'tagged' with RFID tags. Three cohorts of 100 bees (approximately one week apart) were fitted with RFID tags and were introduced to a study colony. RFID readers were fitted to the entrances of the colonies and used to monitor the activity of the tagged bees for the duration of flowering (approx. five weeks). The activity data were analysed to assess any impact of foraging on the treated site compared to the control sites. In addition samples of plants, flower, pollen and nectar were collected during the exposure phase for residue analysis. Colony assessments were made prior to flowering and then at monthly intervals post exposure until the end of overwintering. Under the conditions of this experiment there was no effect of foraging on thiamethoxam treated oilseed rape on honeybee activity, colony development or honeybee colony survival. Additionally, it is possible to use data generated with this relatively new methodology, to assess behaviour and duration of activity for individual bees.

242

#### **Long-term exposure of honeybee colonies with thiacloprid: a field study**

R. Siede, Bieneninstitut Kirchhain; L. Faust, Goethe-Universität Frankfurt am Main / Institut für Bienenkunde; M. Meixner, Bieneninstitut Kirchhain; C.D. Maus; B. Grünewald, Goethe-Universität Frankfurt am Main / Institut für Bienenkunde; R. Büchler, Bieneninstitut Kirchhain

Thiacloprid is a systemic insecticide which is broadly applied to flowering oilseed rape. Residues can occur in matrices in bee hives from colonies foraging on treated oilseed rape. Thus, a long-term exposure of bees with sub-lethal thiacloprid concentrations is a realistic scenario. Its relevance for the colony health, however, is controversially discussed. To improve our understanding of the potential impact of thiacloprid on bee colonies, a field trial with 30 bee colonies was performed in Germany from 2011 to 2014. All colonies were started simultaneously as shook swarms in July of each year and located in an experimental yard. The colonies were divided into three groups of ten colonies each, with colony and year as replicates. The control colonies (C) were each fed with 25 l of pure sugar syrup, colonies of the treatment groups received syrup spiked with 200 ppb (T200) or 2000 ppb thiacloprid (T2000) between July and October. Colonies were weighted and the colony strengths were estimated in intervals of 21 days according to the Liebefeld method. Dead bees were counted regularly. Infestation rates with *Varroa* und *Nosema* were measured. All colonies developed similarly and no differences between the experimental groups were detected. The differences between the groups related to the factor 'treatment' in terms of the performance of the colonies were statistically not significant ( $p > 0.05$ , linear mixed model, spss, v 19). Variances between the experimental years were obvious, but not significant ( $p > 0.05$ ). The increases of weights of the colonies were similar for all three groups. Before and after winter stored food were extracted from the combs and analyzed for thiacloprid and its metabolite. After winter mean residues were 0.012 mg/kg for C (SEM 0.003, med. 0.006), 0.094 mg/kg for T200 (SEM 0.008, med. 0.096) and 0.634 mg/kg for T2000 (SEM 0.034, med. 0.648), underlining the long duration of the exposure of the bees. Nevertheless, neither winter losses nor health problems of colonies in the spring were observed. In conclusion, our results indicate that long-term exposure of realistic thiacloprid doses does not impair colony fitness and survival under field trial conditions.

## **Science communication - Concepts and activities from past and current research projects**

243

#### **Planning of Dissemination Activities in Scientific Research Projects: Strategic Considerations based on Practical Experiences**

T. Gocht, University of Tuebingen / Institute for Experimental and Clinical Pharmacology and Toxicology

The demand for research projects to develop action plans for dissemination and outreach is increasing. Respective requests are formulated in many funding schemes, particularly in the case of collaborative research projects such as large-scale integrated projects funded by the European Commission. In principle, addressing these issues requires clarification of two important points: - What are the target groups of the dissemination strategy? - What are the expectations (of the funders, the scientists) in the dissemination strategy? The first point is obvious and there is no doubt that different target groups (such as the open public or stakeholder groups) must be addressed by different means. The second point seems to be even trivial, as the overall goal of any dissemination strategy is to raise awareness of the target groups on the results of the research project. But: be careful, the devil is in the detail. Assuming that the open public is an important target group, science journalists need to be involved in the process. And the ways how journalists raise awareness was a big source of conflicts in the past („mis-representation“ of the project, „sensationalism“, etc.). Hence, we are confronted with the „how“-question in a traditional area of conflicts between scientists and journalists: how can both groups interact in a way that serves the needs of both of them? This contribution will not give ultimate answers, but formulate suggestions based on practical experiences.

244

#### **Tutorial Video Series: Using Stakeholder Outreach to Increase Usage of ToxCast Data**

C. Baghdikian, US EPA ASPH Fellow / National Center for Computational Toxicology; T. Bahadori, American Chemistry Council; R.S. Thomas, The Hamner Institutes for Health Sciences / Institute for Chemical Safety Sciences, Center for Genomic Biology and Bioinformatics; K.M. Crofton, U.S. EPA / Integrated Systems Toxicology Division NHEERL; M. Linnenbrink, US EPA / ORD

The limited amount of toxicity data on thousands of chemicals found in consumer products has led to the development of research endeavors such as the U.S. EPA's Toxicity Forecaster (ToxCast). ToxCast uses high-throughput screening technology to evaluate thousands of chemicals for potential toxicity. At the end of 2013, U.S. EPA released ToxCast chemical data on almost 2,000 chemicals through the interactive Chemical Safety for Sustainability (iCSS) Dashboard. The iCSS Dashboard provides public access to the high-throughput screening data that can be used to inform the evaluation of the safety of chemicals. U.S. EPA recognized early in the development of ToxCast that stakeholder outreach was needed in order to translate the complex scientific information featured in the iCSS Dashboard and data, with the goal of educating the diverse user community through targeted efforts to increase data usage and analysis. Through survey feedback and the request of stakeholders, a series of tutorial videos to demonstrate how to access and use the data has been planned, and the first video of the series has been released to guide data usage. This presentation will describe the video tutorial strategy including an overview of: 1) Stakeholder outreach goals and approach; 2) Planning, production, and dissemination of tutorial videos; 3) Overview of Survey Feedback; 4) Overview of tutorial video usage statistics and usage of the ToxCast data. This stakeholder-outreach approach is an ongoing effort that has improved public access, understanding, and usability of the iCSS Dashboard and ToxCast data. *This abstract does not necessarily reflect U.S. EPA policy.*

245

#### **FP7 SOLUTIONS project: public communication and dissemination**

D. López Herráez, Helmholtz centre for environmental research - UFZ / Department EffectDirected Analysis; W. Brack, Helmholtz Centre for Environmental Research UFZ / Effect Directed Analysis; S. Consortium, SOLUTIONS

SOLUTIONS is the acronym of the FP7 collaborative endeavour *Solutions for present and future emerging pollutants in land and water resources management*. The project involves organizations from 14 European countries plus Australia, Brazil and China in a major effort in environmental research to ensure future ecological quality of freshwater bodies. The consortium consists of a total of 39 institutions from academia, official authorities and business, and more than 100 professionals with very diverse backgrounds, from computer modelers to laboratory chemists, or from policy experts and social scientists to entrepreneurs. The core medium for raising awareness of SOLUTIONS and the dissemination of its results is an attractive Website [www.solutions-project.eu](http://www.solutions-project.eu) conceived in close collaboration among a professional design agency and the scientific coordination team. A background section serves as front page inviting visitors to learn more into detail about SOLUTIONS motivations easily explained. Simple but captivating images, graphs and icons guide the visitors through the objectives, structure and composition of the project. A news and events section regularly updated informs about latest developments. The Web links to popular social networks such as facebook and twitter where SOLUTIONS is also present displaying expanded information. Given the international nature of SOLUTIONS, regular press releases, TV interviews or newspaper articles in all participating countries and its respective languages are used to disseminate SOLUTIONS. The project's case studies rivers (Danube, Rhine and Ebro) produce news especially interesting for local, regional and national media as well as for popular science magazines. SOLUTIONS seeks for synergies with national and European projects in related areas, e.g. SOLUTIONS puts a strong focus on the collaboration with the FP7 projects on water resources management under multi-stressor conditions MARS and GLOBAQUA. Part of the collaboration with its sister projects is the contribution to posts on the [www.freshwaterblog.net](http://www.freshwaterblog.net) publishing features, interviews and analyses on freshwater conservation, science and policy. This strategy amplifies the propagation of SOLUTIONS news. Internally, SOLUTIONS pursues newest ways of dialog among partners, in the form of e.g. open-space discussions or Science Slam contests, which outcomes can also be used to raise general public attention on the project via the digital channels mentioned above.

246

#### **Public communication and dissemination of structured knowledge gathered in the FP7 SOLUTIONS project through the user-friendly computer tool RiBaTox**

F. Sleenwaert; G. Engelen, Vlaamse Instelling voor Technologisch Onderzoek NV VITO; J. Munthe, IVL Swedish Environmental Research Institute Ltd; J. van Gils, DELTARES; R. Altenburger, UFC Centre for Environmental Research / Department of Bioanalytical Ecotoxicology; W. Brack, Helmholtz Centre for Environmental Research UFZ / Effect Directed Analysis; D. López Herráez, Helmholtz centre for environmental research - UFZ / Department EffectDirected Analysis; S. Comero, European Commission DG Joint Research Centre; A. van Wezel, KWR Watercycle Research Institute / Chemical Water Quality and Health The FP7 SOLUTIONS project searches for new and improved models, tools and

databases to support decisions with respect to emerging pollutants in European water resources. One important output is to provide public access by communication and dissemination of the structured knowledge gathered in SOLUTIONS through a user-friendly computer tool named RiBaTox ('Web-based Decision Support System for River Basin Toxicants'). It will be developed for a very broad end-user community ranging from EU decision makers to the public at large. RiBaTox will be implemented as 'Decision Support System' (DSS). It will guide the end-user to the appropriate models, tools and databases developed in the project to find solutions to stakeholder problems on assessment, prioritisation and abatement of environmental mixtures of emerging toxicants in water resources. The functionality of RiBaTox is foremost determined by the targetted end-users and the system is developed in close collaboration with potential end-users through questionnaires and end-user test groups. This approach requires proper communication and dissemination to the end-user community of preliminary results obtained in SOLUTIONS. A well-balanced communication is needed in order to translate detailed and abstract scientific results in a more comprehensible and plain language suitable for a larger user-community. The iterative 'Evolutionary Delivery software-development Model' (EDM) is applied to implement RiBaTox. Every EDM cycle goes through an intensive implementation phase, end-user communication, testing and assessment phase, revision of end-user requirements phase and system design phase. Currently the first EDM cycle is finalized which resulted in the formulation of the initial functional and technical specifications of RiBaTox. Valuable feedback from potential end-users was received based on a mock-up of RiBaTox distributed among them together with a questionnaire. The second EDM cycle has started with the development of the 'initial' version of RiBaTox. To the effect, continuous feedback will be provided by the 'RiBaTox End-user test Group'. This group of selected potential end-users will meet on a regular basis with a view to obtain a system that focuses maximally on typical problems encountered by end-users, that is transparent and uses a comprehensible and plain language, is user friendly and has a growth potential for future extensions.

## 247

### **Joint knowledge production to improve scientific communication and cross knowledge boundaries**

A.M. Oen, Norwegian Geotechnical Inst. / Dept Environmental Engineering; A. Slob, TNO / Strategy Policy; G. Bouma, TNO; G.D. Breedveld, Norwegian Geotechnical Institute / Department of Environmental Engineering  
The ARCH research project (EU-FP7, 2011-2015) aims to overcome the boundaries between the multiple scientific disciplines involved in the management of lagoon and estuary systems. This includes the challenges of communicating technical information and scientific results which are essential elements in the sustainable management of these complex systems. A central objective of the ARCH research project is to develop participative methodologies in collaboration with stakeholders to manage the multiple problems affecting lagoons in Europe. Two important components towards this goal include (i) the promotion of an integrated research approach and (ii) the employment of a true participatory process. To achieve this goal, participative methodologies have been applied at 10 case study sites throughout Europe. Workshops have been conducted and have focused on knowledge exchange to improve communication and the use of boundary objects and activities to minimize knowledge boundaries. Based on the exchange of scientific, procedural and tacit knowledge, each case study site has suggested management solutions and produced roadmaps for their implementation at the lagoon scale. Observations and experiences from the workshops will be highlighted. This includes evaluating the integrated research approach as well as drawing on comparisons between the different case study sites to explore how the context of their issues influence methods of communication and enabling stakeholders. Working in a highly interdisciplinary way emphasizes the processes of communication and interaction between stakeholders and important factors include: working towards common vocabulary and shared understanding, openness to other disciplines, acknowledging the value of other disciplines, face to face meetings, trust building and joint knowledge production. ARCH builds on the supposition that scientific limitations, including the communication of results at the end of a study, can be overcome by consciously minimizing the boundaries between multiple scientific disciplines at the forefront of investigations and that scientific knowledge can be improved by addressing social systems.

## 248

### **The scientific think tank project Baltic Eye- Science and communication to inform and support decision making for the Baltic Sea environment**

K. Broeg, H. Hamrén, H. Markstedt, Stockholm University / Baltic Sea Centre  
The Baltic Sea, a unique semi-enclosed brackish water sea, has been degraded by pollution and unsustainable fishing for decades. Even though the Baltic Sea countries, the EU, HELCOM, and ICES have recommended and taken numerous measures to reduce contaminant and nutrient inputs and increase fish stocks, the environment has not recovered. There is need to disseminate knowledge on the Baltic Sea ecosystem and the impact of different stressors, alone and in concert, to provide decision support for policymaking. For that purpose, Stockholm University and the BalticSea2020 foundation initiated the scientific think tank Baltic Eye with a core team of seven researchers and three communicators, covering the main impact areas, eutrophication, fisheries, contaminants and agriculture. Baltic Eye seeks society's need for knowledge as well as the relevant communications,-

policy-, and decision landscapes. With respect to contaminants, Baltic Eye acts as an arena for synthesizing existing and initiating new scientific knowledge, building-up networks, and communicating information on sources, fate and impacts as well as suggesting measures. Communication mainly targets decision makers at regional, national, and European levels. As an example, the Baltic Eye project on microplastics in the Baltic Sea and its communication strategy is presented.

## 249

### **Chemical Speciation of Organotin Compounds in Seawater from Cape Town Harbour, South Africa; Seasonal variations and their Toxicity Effects**

O.S. Fatoki, Cape Peninsula University of Technology / Chemistry

Water samples were collected in twelve locations from Cape Town harbour in order to assess their tributyltin and triphenyltin contamination. Moreover, seasonal variation and their toxicological effects were examined using biomarkers. The annual concentration ranges from  $0.067 \pm 0.01$  to  $111.290 \pm 32.20 \times 10^{-3} \mu\text{g/l}$  for TBT while that of TPT ranges between  $23008.0 \pm 0.03 \times 10^{-3} \mu\text{g/l}$  respectively between locations. The seasonal variation of TBT was also investigated; significant variation of  $P \leq 0.05$  was found after the statistical analysis. Seasonal variation in TBT and TPT concentrations with a higher level in summer than in winter and spring has been observed. Apparently, the observed high or low value recorded for organotin compounds in Cape Town harbour could be as a result of increase or decrease in the traffic of ships and boats. More over dilution due to increase in water volume results in decrease in concentration of TBT. High value observed for TBT in summer could be associated to steady flow of water, while in spring, the ocean tide effect may suggest reason why we have more TBT in spring or low but this also depends on the direction of the tide. The toxicity effects of tributyltin were investigated using responses of lysosomal membranes of hemocytes of the mussel, *Mytilus galloprovincialis*, as a biomarker of stress due to exposure to tributyltin. Apparently, from this study, for both exposures group NRR time became progressively shorter as TBT concentration increasing with time. This study has revealed that the two contributing factors influencing lysosomal responses are exposure concentration and exposure time of TBT. The NRR time assay could be considered as a useful cellular biomarker of stress due to tributyltin exposure.

### **Civil Aviation Initiative on Climate Change Impact Assessment on Ground Water Resources in Libya**

D.P. Bindra, Civil Aviation / UNCSD Rio Focal Point

This paper is designed to present the likely impact of climate change mainly due to increased human activities like growing aviation industry & petroleum E&P on groundwater resources in general and Libya in particular. State of the art reviews on recent research studies, and methodology to assess the impact of climate change on groundwater resources shows that climate change poses uncertainties to the supply and management of water resources. It outlines to demonstrate that how climate change impact assessment plays a vital role in forming the sensitive water balance rarely achieved in most area owing to precipitation variability's and seasonality. It demonstrates that how large increases in water demand with very little recharge from precipitation have strained Libya's groundwater resources resulting in declines of groundwater levels and its quality, especially on Libyan coastal areas where most of the agriculture, domestic and industrial activities are concentrated. Based on several research studies to combat GHG like Green Sky Initiative of Civil Aviation College Sbia in Libya it demonstrates that how policy and decision making process using best practices for monitoring, analyzing and forecasting variation of climate is a way forward to cope with the impact of sea level rise, and combat some water supplies in vulnerable areas that are becoming unusable due to the penetration of salt water into coastal aquifers. Finally, interesting results from a number of initiatives like sustainable aviation using green sky initiative in the form of posters by students are reviewed to demonstrate that how better understanding of climate and climate change forecasting helps in devising appropriate adaptation strategies due to the impact of climate change.

## 251

### **Evaluation of the potential of the Microbial Assay for Risk Assessment of herbicides**

P.B. Bi Asanga Fai, Ecotoxicologist Senior Lecturer / animal biology; M. Mpoame, N. Norbert, P.F. Tankie, University of Dschang / Department of Animal Biology  
Pesticides, especially insecticides and fungicides, are more heavily applied to tropical cash crops, e.g. banana, coffee, cotton, and vegetables, than to crops in temperate regions. A big data gap exists in Africa as far as levels of pesticides and toxic effects in the environment are concerned. The microbial Assay for Risk Assessment (MARA) is a multi-species test with 11 taxonomically diverse microbial strains freeze-dried in a 96-well microplate used to assess the ecotoxicity of chemicals and environmental samples. However there is little published data on the sensitivity of MARA test to pesticides, particularly herbicides. This research set out to investigate how representative MARA bioassay responses are of effects of herbicides in the aquatic ecosystem with the aim of establishing how useful it can be

in filling in the data gap. In this research we compared the sensitivity of MARA to a fish bioassay using two commonly used herbicide formulations: Round up (a.i. glyphosate) and herbextra (a.i. 2,4 D). The mean MARA MTC for glyphosate was 101.82 mg/l with a range of MTCs from 6.85 to 172 mg/l for the various microorganisms. In the case of 2,4-D MTC values obtained ranged from 74.67 mg/l to 13,333.33 mg/l with a mean value of 2855.88 mg/l. On the other hand, 96 h EC50s (and corresponding 95% confidence intervals) obtained from *Oreochromis niloticus* fingerlings were 11.26 (10.5-11.64) µg/l, 222.28 (209.86-228.11) µg/l and 23.07 (21.95-24.35) µg/l respectively for glyphosate and 2,4-D. The two herbicides were highly toxic to the MARA microorganisms at environmentally relevant concentrations with glyphosate being at least 20 times more toxic than 2,4-D. However, when compared to effects on fish, the MARA microorganisms were far more tolerant to the herbicides showing that MARA microorganisms responses do not reflect responses from aquatic organisms from all trophic levels. This implies that while the MARA test may have a great potential for assessing ecotoxicological effects of pesticides and other environmental pollutants on the microbial community, for better protection of aquatic ecosystems other bioassays are necessary to be included in the test battery, particularly algal or plant bioassays.

### Monitoring of fluoroquinolone antibiotics in piggery wastewater and their mobility in solid materials after the application of the slurry as fertilizer

**V.D. Litskas**, Department of Civil and Environmental Engineering University of Cyprus; **A.K. Parpounas**, NIREAS-IWRC / Civil and Environmental Engineering University of Cyprus; **E. Hapeshi**, C. Michael, University of Cyprus / NIREASInternational Water Research Center; **D.F. Kassinos**, NIREAS-IWRC / Civil and Environmental Engineering

Enrofloxacin (ENR) is regularly administered, in a global scale, in concentrated animal feeding operations (CAFOs) for therapeutic and prophylactic purposes. As a result, the repeated application of contaminated animal wastewater as fertilizer could enrich the soil with ENR and its major metabolite, ciprofloxacin (CIP). Nevertheless, data for their presence and concentrations in animal wastewater are limited, as well as data for their mobility in soils. In this study, piglets' urine and faeces mixture samples as well as piggery wastewater samples were collected from several points (e.g. pregnant and nursery facilities, weaning facilities, primary wastewater collection tank) in a CAFO located in Cyprus to monitor ENR and CIP. The present study describes the development and application of a fast and accurate analytical method for the investigation of the occurrence of fluoroquinolones (FQs) in piggery wastewater, using off-line solid phase extraction (SPE) followed by UPLC-MS/MS. The extraction procedure based on the formation of FQs-Mg<sup>2+</sup> complexes allowed the desorption and extraction of both antibiotics from wastewater, which was not feasible by using conventional organic solvents. The recoveries for both antibiotics from wastewater were up to 85% and limit quantification was lower than 1 µg L<sup>-1</sup>. In addition, batch equilibrium studies were performed to examine the adsorption of ENR and CIP in a clay soil, in quartz sand and in solid material from swine slurry. The results showed that ENR concentrations in the collected wastewater samples ranged from 7 to 40 µg L<sup>-1</sup> while the concentration range for its metabolite, CIP, was 2-33 µg L<sup>-1</sup>. The adsorption experiments showed that clay soils as well as the solid material from swine slurry have a great potential to immobilize these antibiotics. The concentration specific adsorption distribution coefficient (K<sub>d</sub><sup>ads</sup>) values ranged from 412 – 5075 L kg<sup>-1</sup> for ENR and 155 – 3365 L kg<sup>-1</sup> for CIP, respectively. The swine slurry solid material has shown the higher adsorption capacity for both the antibiotics, followed by the clay soil and the quartz sand. Our results indicate the presence of ENR and CIP in the swine wastewater, even when the antibiotics are administered at low doses. The soil properties (e.g. clay, silt, sand, organic matter content) determine its ability to immobilize ENR and CIP antibiotics and consequently the capacity of the terrestrial ecosystem to assimilate them.

## 253

### Removal of PFOS and PFOA from aqueous solutions using activated charcoal of *Vitis vinifera* leaf litter

**B.O. Opeolu**, Cape Peninsula University of Technology / Faculty of Applied Sciences; **B.O. Fagbayigbo**, Cape Peninsula University of Technology / Environmental health and occupational studies; **O.S. Fatoki**, **B.J. XIMBA**, **O.S. Olatunji**, Cape Peninsula University of Technology / Chemistry

In recent times, quality of freshwater resources have been deteriorating due to pollution from diverse sources. In Africa, emerging contaminants such as PFOS and PFOA are becoming prevalent in environmental samples. Negative effects of compounds such as PFOS and PFOA on man and environment have been reported elsewhere. The need for similar studies in Africa and other developing countries cannot be over-emphasized given the current drive of developing nations' for industrialization. It is therefore important to proactively consider ways of protecting ecosystems from pollution. In this study, activated carbons sourced from waste leave biomass of *Vitis vinifera* were investigated in order to evaluate their efficiencies as adsorbents for removal of PFCs from water. *V. vinifera* leave biomass debris was collected from wine farmland in Stellenbosch, Western Cape South Africa. The leave biomass was air dried, pulverized, carbonized under N<sub>2</sub> gas at 550°C and treated with 1M phosphoric acid and 1M potassium hydroxide. Batch experiments were carried out to obtain data for adsorption equilibrium isotherms and fitted into kinetic models using simulated wastewaters containing

perfluorinated compounds. The effects of concentration, pH and adsorbent dosage on the removal efficiency of the PFCs were observed. Data fitted well into the Freundlich isotherm model. There was increasing removal of the PFCs with increasing concentration with an optimum value of 0.75 µg/mL. Adsorption of PFOS and PFOA were best described by Freundlich model for acid activated charcoal with R<sup>2</sup> values 0.9937 and 0.9992 respectively. Corresponding values for KOH activated charcoal were 0.9983 and 0.9989. The Freundlich model suggests multi-layered adsorption. Values of n evaluated from the slope of the plots are indicative of favourable adsorption. Increased adsorbent dosage also enhanced removal of PFOS and PFOA. Adsorption kinetics was best fitted into Pseudo second order kinetics with R<sup>2</sup> values 0.991 and 0.985 for PFOS and PFOA respectively with KOH activated charcoal. Corresponding values for H<sub>3</sub>PO<sub>4</sub> activated charcoal were 0.9234 and 0.8477. Maximum adsorption capacities q<sub>max</sub> are 140 mg/g and 107 mg/g for PFOS and PFOA respectively.

## 254

### Life in a polluted environment: an interdisciplinary approach on the effects of contaminants in the brown shrimp, *Crangon crangon*

**D. Mondal**, University of Salford / Environmenta and Life Sciences; **C. Benvenuto**, University of Salford / Environment and Life Sciences

**Introduction:** The brown shrimp *Crangon crangon* L. (Decapoda, Caridea) is distributed all along the European coasts and uses estuarine areas, potentially impacted by human pollution as nursery ground. Like many other crustaceans, these shrimp play a key role in the ecosystem and are economically important as key components of food webs while providing with a significant source of protein in our diet. We aim to use *C. crangon* as bioindicator and biomonitor of environmental quality, in particular to detect the effects of environmental pollutants on morphological, physiological, behavioural and life-history adaptations, as well as on its fascinating mating strategies. Our sampling site is a unique semi-isolated pool near the Upper Mersey River, Widnes, UK. Hence, collecting the shrimp from a confined polluted environment from a historically contaminated area makes our project significantly different compared to studies done only in the laboratory by dosing the animals. **Methods:** Samples were collected for shrimp, sediment and water from the sampling pool along with three other locations (Mersey River, estuaries at Milford Haven, Wales, and Praia de Faro, Portugal) for comparative studies. Analyses of heavy metals and PCBs in the whole body of shrimp along with the sediments and water were performed following established protocols. **Molecular analyses** to assess genetic variation and microbiota were piloted. **Behavioural studies** like chromatophore experiments and sex changing experiments are in progress. **Histopathological and cytotoxicological tests** are being conducted. **Results:** Heavy metal sediment concentrations were up to two orders of magnitude higher in the sampling pool compared to the three other locations (p<0.05), while the concentrations in the water were comparable. Keeping in mind that these animals are benthic, surprisingly, the xenobiotics like arsenic and chromium were lower in the shrimp collected from the sampling pool compared to the other areas (but not significantly, p>0.05). PCB concentrations were higher in the shrimp collected from the sampling pool. **Conclusion:** The presence of high concentration of heavy metals in the sediment compared to low bioaccumulation in the tissue of the shrimp collected from the sampling pool leaves us with questions on adaptation strategies of the shrimp dwelling under this special environmental condition and we are in the process of addressing these based on the on-going experiments.

## Epigenetic effects of chemicals in ecological and human risk assessment: challenges and perspectives

## 255

### A new paradigm in chemical hazard assessment: Chemicals do not induce genomic mutations but are epigenetic agents!

**J. Trosko**, Michigan State University / Department of Pediatrics Human Development

The foundation of a rigorous risk assessment is a scientifically- sound understanding of the mechanisms by which chemicals cause various health effects. There are three mechanisms of toxicities, “mutagenesis”; “cytotoxicity” and altered expression of gene expression at the transcription, translation and posttranslation levels or “epigenetic toxicity”. Given the prevailing paradigm of chemical toxicities has been that of “genotoxicity”, a challenge will be made that chemical toxins/toxicants do not cause genomic DNA damage or mutations that contribute to birth defects, to the multi-stage, multi-mechanism process of carcinogenesis, immune-toxicity, reproductive – or neuro-toxicities. Rather, the primary mechanism associated with natural and synthetic chemicals, to which multi-cellular organisms are normally exposed to in water, air, pharmaceuticals, in or on foods, during food processing, and supplements, is that of the inappropriate modulation of extra-, intra- and inter-cellular communication. This delicate and integrative series of communication mechanisms is the basis for homeostatic control of cell proliferation, differentiation, apoptosis and senescence of organ-specific adult stem cells. While mutations do contribute to germ-line and somatic diseases, such in as xeroderma pigmentosum (“errors in DNA repair”) and Blooms syndromes (“errors in DNA replication”), non-mutagenic chemicals, such as DDT, phorbol esters, PBB's, PCB's, TCDD's, phenobarbital, phthalates, bisphenol A, estrogen, poly aromatic hydrocarbons, thalidomide, asbestos, aflatoxin, etc., all of which can

induce ROS's and induce oxidative stress, trigger various intra-cellular signaling to (a) modulate gap junctional or extra-cellular signaling to disrupt homeostasis in a multi-cellular organism. This class of epigenetic agents is characterized by (a) having species, gender, developmental stage specificities; (b) having threshold levels of action; (c) exhibit toxic consequences during "critical windows" during development or during regular & chronic exposures in the adult; and (d) must be present in the absence of antioxidant agents. Understanding the many specific mechanisms by which these epigenetic chemicals can modulate the quality and quantity of stem cells is critical if we hope to have rigorous risk assessment. Disruption of the quantity of organ-specific adult stem cells during fetal/neonatal development is probably the mechanism behind the "Barker Hypothesis".

## Interpreting Biological Effects of Metals and Their Mixtures (II)

261

**Evaluation of immune and acclimation capacities of the three-spined stickleback (*Gasterosteus aculeatus*) in polymetallic contamination context.**

A. Le Guernic, IRSNRP-ENVLECO / BouchesduRhône; w. sanchez, FCS Rovaltain / General Direction; S. Betoulle, Université de Reims; B. Gagnaire, In an ecosystem, organisms are exposed to multiple and different stressors. These stressors can act individually or in combination. Studies start to take into account these multiple stressors and environmental variations for ecotoxicologic risk assessment. The aim of this study was to evaluate the impact of polymetallic contamination on acclimation capacities of a fish, the three-spined stickleback, after a stress challenge (chemical and biological). Chemical stress was defined by the polymetallic contamination linked to former uranium mines. Moreover uranium other trace metals, naturally occurring (Fe, Mn) or introduced by man to precipitate uranium and its decay products (Ba, Al), increased the metal contamination of these sites. Three-spined sticklebacks were caged in three ponds in Haute-Vienne department (France). A pond was chosen for its proximity to former uranium mines (Pontabrier pond) and two other ponds were selected outside the influence of these tailings (Malessard and Jonchere Saint-Maurice). Two *in situ* experiments were conducted to know if season (April and September-December) and duration of metallic exposure impacted stress responses of sticklebacks to LPS. Fourteen days after metallic exposure (chemical stress) for the first experiment and after 76 days for the second, fish were subjected to an injection of lipopolysaccharide (LPS) corresponding to a biological stress. Finally, four days after injections, sticklebacks were euthanized for analysis of immunotoxicity, oxidative stress and genotoxicity. Although the concentrations of iron, aluminum and manganese were important for each pond, the highest metal concentrations were found in the pond subjected to mine tailings (Pontabrier), especially for uranium. Chemical stress impacted negatively the major biological functions analysed in stickleback, as well as the biological stress. Chemical stress reduced responses of sticklebacks to biological stress by decreasing phagocytic and antioxidant responses to LPS. Nevertheless, environmental variables had impacts also on some biomarkers analysed. Results of the second experiment will help to know if season or exposure period had an impact on responses recorded.

262

**Mixture toxicity for metals in the environment: potential for refinement of the concentration addition approach.**

K. Oorts, ARCHE; C. Moens, Katholieke Universiteit Leuven / Division Soil and Water Management; F. Verdonck, ARCHE

The assessment of mixture toxicity of naturally occurring elements, such as metals, in the environment based on information on the individual components is challenging. Several important aspects, such as natural background concentration, essentiality, differences in bioavailability significantly affect the outcome of the assessments. For several metals, the predicted no-effect concentrations (PNEC) are close to their natural background concentration, and adding the predicted potential effect of several metals may lead to over-protective results and even identification of risks in the natural environment. In the absence of adequate mode of action information for all components, the concentration addition (CA) method is the default, conservative concept for estimating toxicity from chemical mixtures. Furthermore, concentration addition can be applied based on the available toxicity data (EC10, EC50, ...) for the individual components and additional testing is therefore minimized. Recently, a tiered approach for mixture toxicity assessment of biocides was published (ECHA, 2014). In this document, some refinements of the standard CA method are presented. These approaches were applied for prediction of mixture toxicity for metals in water and soil. The results demonstrate limited potential for improvement of the standard concentration addition approach for a multi-metal mixture, even when the assessment is based on species-level. Correct prediction of potential effects of the individual components at low exposure (i.e. below PNEC) is critical for prediction of mixture toxicity. However, the standard linear extrapolation of effects and risks between the toxicity threshold (e.g. PNEC) and absence of a substance in the environment generally yields an overestimation of potential risks at low exposure concentrations. When sufficient data are available for the derivation of a species sensitivity distribution for the individual components, it is therefore proposed to use the potentially affected fraction at the exposure concentration of the individual metals as a basis for the summation in the concentration addition approach.

263

**Incorporating bioavailability into toxicity assessment of Cu-Ni, Cu-Cd, and Ni-Cd mixtures with the extended biotic ligand model and the WHAM-Ftox approach**

H. Qiu, Leiden University; M.G. Vijver, CML Leiden University; E. He, VU University Amsterdam / Department of Ecological Science; W.J. Peijnenburg, RIVM / Center for Safety of Substances and Products

Seedlings of lettuce *Lactuca sativa* were exposed to metal mixtures (Cu-Ni, Cu-Cd, and Ni-Cd) contained in hydroponic solutions for 4 d and inhibition to root elongation was the parametric endpoint used to quantify toxic response. The general objective is to incorporate bioavailability in the assessment of mixture toxicity using the the extended biotic ligand model and the WHAM- $F_{tox}$  approach. By adopting an  $f_{mix}$  value, the extended biotic ligand model succeeded to predict toxicity of Cu-Ni, Cu-Cd, and Ni-Cd mixtures to *L. sativa*, with more than 82% of toxicity variations explained. The validity of the model suggests that competition is the dominant mechanism accounting for interactions between mixture components. There were no significant differences in the values of  $f_{mix50}$  for the three mixture combinations, showing the possibility of extrapolating these  $f_{mix50}$  values to other binary metal combinations. The WHAM- $F_{tox}$  approach, postulating that competitive chemical reactions at one or more biotic ligands of the organism can be represented by the competitive binding to particulate humic acid, had a similar level of precision in estimating mixture toxicity while requiring fewer parameters than the BLM- $f_{mix}$  model. External validation of the WHAM- $F_{tox}$  approach using literature data showed its applicability for other species and other mixtures. Generally, the WHAM- $F_{tox}$  model works when the BLM also works. Based on our finding, the WHAM- $F_{tox}$  is recommended as an effective approach to incorporate bioavailability in quantifying mixture toxicity. Theoretically, the WHAM- $F_{tox}$  approach can be applied to predict toxicity of binary, ternary, and quaternary (or even more) metal mixtures, provided that competition at the biotic ligand can be simulated on the basis of assumptions of competition at abiotic ligands.

**Four methods to estimate potential risks of metal mixtures: a case study for Flemish waterways**

T. Van Regenmortel, Laboratory of Environmental Toxicology and Aquatic Ecology GhEnToxLab Unit; C. Janssen, University of Ghent / Laboratory of Environmental Toxicology and Aquatic Ecology GhEnToxLab unit; K.A. De Schampelaere, Ghent University (UGent) / Laboratory for Environmental Toxicology and Aquatic Ecology GhEnToxLab unit

In the EU and world-wide, the assessment and management of potential risks posed by chemicals is almost exclusively based on evaluations of individual substances. This study evaluates potential risks of metals occurring in four-metal (Cu, Zn, Ni, Cd) mixtures when each metal is present in the environment at its biotic ligand model (BLM) based, bioavailability-corrected environmental concentration. Four different methods - combining the concentration addition (CA) model or the Independent Action (IA) model with Species Sensitivity Distributions (SSD) in four different ways - were used, critically evaluated, and compared. For all four metals, high-quality chronic EC10s, EC50s and the corresponding water characteristics were compiled in a database. Using biotic ligand modelling, all

EC10 values were normalized to the physico-chemistry of 169 Flemish water bodies. The information of these water bodies was collected from databases of the Flemish Environmental Agency. Using CA and IA, the fraction of potentially affected species per water body and the percentage of water bodies affected was evaluated. A water was considered 'potentially affected' when the Potentially Affected Fraction (PAF) of species was higher than 5%. Results indicate that the most simple of the four methods, i.e. the CA-SSD method, predicts the highest percentage of water bodies affected (34%), and is therefore the most conservative method. However, of these 34% waters that are potentially affected, only 28% are affected by the mixture itself, and not already by the individual metals. Potential risks caused by metal mixtures seem to be dominated by risks caused by individual high Zn concentrations (58%). When examining potentially affected waters caused by specific mixture effects, Zn and Cd contribute the most to the mixture effect (37 and 30%, respectively). This study demonstrates that using CA and IA for the risk assessment of metals implies that environmental risk will be predicted for a substantial amount of water bodies in the Flemish waterways. However, mixture specific risks, in contrast to mixture risks caused by individual substances alone, are limited. The outcome of the four methods used here show small differences. However, the validity of these predictions needs to be further evaluated using dedicated laboratory and field studies.

## 265

### New advanced methods for modelling toxicity of metal mixtures to plants

Y.T. Le, Radboud University Nijmegen / Environmental Science

No single chemical properties have been found to be able to explain the variations in metal toxicity. Besides environmental chemistry, biological responses of plants exposed to metal mixtures are affected by interactions between the metals and interactions of the metals with the plants. These interactions might be taken into account in estimating metal toxicity to plants with three methods applied recently. The first method is based on the assumption of the Biotic Ligand Model (BLM) that metal accumulation at biotic ligands, which is influenced by competition between metal ions for binding sites at the ligands, determines toxic effects (BLM-based). The second assumes that metal sorption to the plasma membrane, which is determined by the electrical potential at the membrane, is directly related to metal toxicity (electrostatic model). In the last approach, metal accumulation in roots, which links to biological responses, is simulated by metal binding to humic acid in geochemical speciation models (WHAM-based model). These models can be generalised as using metal affinity for binding sites on sorption surfaces (i.e., biotic ligands, plasma membrane surface, and humic acid) as a unifying factor of metal toxicity. The potential of the three models for estimating the toxicity of  $\text{Cu}^{2+}$ - $\text{Zn}^{2+}$  and  $\text{Cu}^{2+}$ - $\text{Ag}^+$  mixtures to lettuce *Lactuca sativa* was evaluated with the same concept, i.e., toxic unit. The potential for simulating ion-ion interactions was the decisive factor for predicting toxicity of metal mixtures with these models. The electrostatic model was found least effective while the WHAM-based model was only slightly better than the BLM-based model in predicting the growth of lettuce roots exposed to the mixtures. These results are potentially related to the negligible variations in the electrical potential at the plasma membrane surface and the mechanisms of ion-sorption surface interactions simulated in these models. Both electrostatic interactions and metal/site-specific binding at sorption surface are included in the WHAM-based model. The former is excluded in the BLM-based model while the latter is not completely addressed in the electrostatic model.

## 266

### Mixture toxicity of Cu, Ni, Cd and Zn to barley can conservatively be predicted by the concentration-addition model

L. Versieren, EES; K.A. De Schampelaere, Ghent University (UGent) / Laboratory for Environmental Toxicology and Aquatic Ecology GhEnToxLab unit; R. Blust, University of Antwerp / Systemic Physiological and Ecotoxicological Research Department of Biology; E.E. Smolders, Katholieke Universiteit Leuven / Division Soil and Water Management

Metal contamination is most often a mixture of different metals and these multi-component mixtures could produce significant mixture effects. There is a need to understand how metals act together in producing combination effects, especially at low effect concentrations of the individual metals. The present study aims to investigate and predict toxicity and interactions of multiple metal mixtures (Cu, Ni, Cd and Zn) to barley root elongation in nutrient solutions at metal concentrations individually causing low level effects. Both the CA and the IA reference model were used to predict toxicity in the mixture treatments based on single metal toxicity data. The results show that a mixture of different metals at concentrations singly causing only slightly toxic effects can lead to significant mixture effects. The IA model predicted RRE better than the CA model, suggesting different of modes of actions of the metals in the mixtures. The CA model, however, is generally more conservative than the IA model and can be used as a save model to predict metal mixture toxicity to barley. Mixture treatments with binary and ternary combinations of Cu, Ni and Cd generally produce small synergistic or additive interactions, whereas mixtures with elevated Zn concentrations lead to additive and antagonistic interactions, mainly Cd + Zn mixtures cause antagonistic interactions.

## Plastics in the Aquatic Environment: Mechanisms and

## Implications (II)

## 267

### Ingestion of microplastics by freshwater invertebrates

C. Scherer, Aquatic Ecotoxicology; N. Brennholt, Federal Institute of Hydrology / Biochemistry and Ecotoxicology; G. Reifferscheid, Biochemistry and Ecotoxicology; M. Wagner, Goethe University Frankfurt / Aquatic Ecotoxicology Plastic items are accumulating in aquatic systems worldwide. Under environmental conditions, plastic materials degrade to so-called microplastics (MP, < 5 mm). Although laboratory studies demonstrate an uptake of MPs by a broad range of marine species, data on freshwater organisms are lacking. To evaluate the uptake and fate of microplastics in freshwater invertebrates and to establish a basis for future ecotoxicological studies, we conducted ingestion studies with MPs and freshwater invertebrates. *Daphnia magna*, *Gammarus pulex*, *Chironomus riparius* and *Physella acuta* were exposed to different concentrations (3-3000 particles  $\text{mL}^{-1}$ ) of fluorescent polystyrene particles (1, 10 and 90  $\mu\text{m}$  in diameter) in short-term experiments. To test the influence of additional natural particles, we included food or sediment in our testdesign. Our results clearly demonstrate that freshwater invertebrates ingest and accumulate high amounts of MPs. In the presence of natural particles (food/sediment), the overall ingestion as well as the ingestion rates decreased. We conclude that MP ingestion is determined by the size of the particles as well as the feeding behavior, the stage of development and the size of the organisms.

## 268

### Potential effects of microplastics on limnic zooplankton

S. Rehse, Leibniz-Institute of Freshwater Ecology and Inland Fisheries / Ecophysiology and Aquaculture; W. Kloas, Leibniz Inst. of Freshwater Ecology & Inland Fish.; C. Zarfl, University of Osnabrueck / Center for Applied Geosciences Microplastic particles (< 1 mm) are not only abundant in marine but also in freshwater ecosystems. Once introduced into the environment microplastics tend to release additives and absorb environmental pollutants. While there is evidence that microplastics can cause adverse effects in marine organisms, not much is known about the fate and effects of microplastics in freshwater systems. Our aim is to systematically test the uptake and effects of microplastics on freshwater organisms on different levels of the food chain. In a first step, we exclude chemical effects, e.g. by additives or attached pollutants, by using raw microplastic particles. As a model organism for limnic zooplankton we exposed *Daphnia magna* to different types of microplastics (polyethylen, 1 and 100  $\mu\text{m}$  particles). Before exposing neonates of *D. magna* the behaviour of the particles in water was characterized. Both particle sizes (1 and 100  $\mu\text{m}$ ) tended to float at the water surface. However, the majority of 1  $\mu\text{m}$  particles remained in the water column after vigorously shaking. In contrast, the 100  $\mu\text{m}$  particles were floating back to the surface immediately after mixing. This led to different exposure scenarios for the daphnids. After exposure, the 1  $\mu\text{m}$  particles were ingested by the daphnids and attached to the carapax. Both uptake and accumulation of 1  $\mu\text{m}$  particles increased with higher concentrations. The 100  $\mu\text{m}$  particles, in contrast, were neither ingested nor accumulated at the carapax. We conclude that different sizes of microplastics (1) lead to different behaviour in water followed by different exposure scenarios for organisms and (2) induce different effects, e.g. like physical effects by accumulation on the surface of the carapax of daphnids. Attached particles might cause problems with molting and lead to differences e.g. in growth. Our results thus provide a first basis to systematically identify parameters of microplastics that determine adverse impacts on freshwater organisms on different levels of the food chain.

## 269

### Nanoplastics impacts on marine organisms: accumulation and toxicity of polystyrene nanoparticles in three target species

e. bergami, University of Siena / Physical Earth and Environmental Sciences; C. Della Torre, University of Siena / Department of Physical Earth and Environmental Sciences; C. Ciacci, University of Urbino; A. Salvati, University College Dublin / Centre for BioNano Interactions School of Chemistry and Chemical Biology; e. bocci, University of Siena; M. Vannuccini, University of Siena / Physical earth and environmental science; c. faleri, University of Siena / Department of Life Sciences; p. cirino, Anton Dohrn Zoological Station; K.A. Dawson, University College Dublin / Centre for BioNano Interaction School of Chemistry and Chemical Biology; L. Canesi, university of genoa / DISTAV; I. Corsi, University of Siena / Physical Earth and Environmental Sciences

Nanoplastics debris represent an emerging concern for marine ecosystems. Nevertheless, their fate and impact on marine biota is almost unknown. Polystyrene nanoparticles (PS NPs) can be considered as model for studying both fate and toxicity of nanoplastics in marine organisms. Marine invertebrates are considered primary biological targets of polymeric NPs, being exposed both in the water column (phyto- and zooplankton) including bivalves and in sediments (grazers and bottom feeders). For this purpose, the present study evaluated the accumulation and toxicity of 40 nm anionic carboxylated (PS-COOH) and 50 nm cationic amine (PS-NH<sub>2</sub>) NPs in three target marine species: brine shrimp *Artemia salina* larvae, mussel *Mytilus galloprovincialis* tissues and sea urchin *Paracentrotus lividus* early development. Secondary characterisation of PS NPs in natural sea water (NSW) (0.45  $\mu\text{m}$  filtered, T 18°C, salinity 39‰, pH 8.3, conductivity 6 S/m) was

performed using DLS analysis. PS-COOH resulted massively sequestered inside the digestive tract of sea urchin embryos at 48 hours post-fertilization and brine shrimp after 48 h exposure. PS-COOH were exchanged between gills and circulatory system after 2 h of exposure and accumulate in lysosome of mussel's haemocytes. No relevant toxicity was observed for PS-COOH in all three target species. PS-NH<sub>2</sub> resulted less clear disposed both in brine shrimp larvae and sea urchin embryos and but induced molting and caused severe alterations, respectively. In mussels' haemocytes, exposure to PS-NH<sub>2</sub> caused an increase in extracellular ROS and NO production and also dose-dependent modulation in phagocytosis and lysozyme activity was observed. The clear differences in accumulation and toxicity of PS-COOH and PS-NH<sub>2</sub> might be related to their surface charge and aggregation in sea water. Our findings suggest that these three species are vulnerable to PS NPs and further research is strongly encouraged on specific pathways of toxicity in marine organisms.

270

#### **Formation of microplastics and bioaccumulation of toxic additives by lugworm inhabiting in expanded polystyrene marine debris**

M. Jang, Korea Institute of Ocean Science and Technology / oil and POPs research group OPRG; S. Hong, Korea Institute of Ocean Science and Technology / Oil and POPs research group; G. Han, Oil and POPs research group; M. Rani, Korea Institute of Ocean Science and Technology; Y. Song, Oil and POPs research group; W. Shim, Korea Institute of Ocean Science and Technology / Oil and POPs research group

Defined as less than 5 mm in size, numbers of microplastic has increased in oceans worldwide. Fragmentation of plastics in the environment was expected mainly at beaches where photo-degradation and abrasions take place through wave actions. However, bioactivities of organisms in floating plastics could also contribute to the formation of microplastics. Large amounts of expanded polystyrene (EPS) buoys have been used in aquaculture activities in South Korea. Lugworm (*Marphysa sanguinea*) is a marine organism generally found in mud and rock. Interestingly, many burrows of this specie were found inside EPS buoy while searching organisms inhabiting on EPS buoy. In our previous study, considerable amounts of HBCDs in EPS buoys were detected. HBCD has been categorized as a persistent organic pollutant and is now listed in Stockholm convention in 2013. We try to determine (1) whether microplastics are created by burrowing of lugworm, and (2) lugworm can accumulate additive HBCDs from EPS buoy. EPS buoys were collected from the coasts of Geoje in South Korea. After collection of EPS buoys, lugworms and EPS particle inside burrows were sampled. Sampled lugworms were kept separately for 3 days for cleaning of gut and collection of excretions. EPS particles in lugworm's excretions identified using FTIR were roughly globular in shape. The size of EPS particles were varying according to the size of lugworm. The maximum length (length means the longest axis of EPS particles) and median length were 3.79 mm and 1.26±0.83 mm for large size lugworm (weight: 6.38 g, length: 26 cm), and 1.97 mm and 0.8±0.42 mm from small size lugworm (weight: 3.27 g, length: 14 cm), respectively, displaying dependency on mouth size of lugworm. The mean number and weight of EPS particles per excretion from lugworms (n=10) were 132±121 and 2.25±3.17 mg, respectively. HBCDs were detected in all lugworms even after cleaning their guts. Significant difference in HBCDs concentration was found according to their substrate types, indicating that toxic additives in EPS debris are directly affecting to its inhabitants. This study presents that burrowing activities of lugworm can produce microplastic particles and release them to the marine environment. Lugworms inhabiting EPS marine debris accumulate HBCDs from their substrates, which could lead to the biomagnification of the toxicants in the marine food web.

271

#### **Chemical Pollutants Adsorbed to Microplastics Bioaccumulates in Exposed Fish**

P. Wardrop, RMIT University / School of Applied Science; J. Shimeta, P. Morrison, RMIT University; A.F. Miranda, School of Applied Sciences / School of Applied Sciences; M. Tang, D. Nugegoda, B. Clarke, RMIT University / School of Applied Sciences

The contamination of the natural environment with plastic debris is an increasingly high-prioritised concern among regulators, scientists and citizens. Aside from negative impacts on natural aesthetics, plastic debris causes a range of ecological harm from entanglement to starvation when mistakenly ingested by animals. Plastic adsorbs and concentrates pollution from the surrounding environment but the role that plastic debris plays in the movement of chemical pollution and contamination of food chains is largely unknown. Recent studies show that plastics facilitate the bioaccumulation of pollution to a variety of exposed organisms. Here we show for the first time that fish fed small microplastic particles (s-MPPS), isolated from a commercial facial cleanser and contaminated with the persistent organic pollutants polybrominated diphenyl ethers (PBDEs), bioaccumulated PBDEs in their tissues.

272

#### **Relative importance of PCB uptake from sediment and microplastic by the lugworm *Arenicola marina* (L.)**

E. Besseling, Wageningen University & Research Centre / Aquatic Ecology and Water Quality Management Group; E. Foekema, Wageningen IMARES; M. Van den Heuvel-Greve, Wageningen IMARES / Marine Coastal Systems; A.A.

Koelmans, Wageningen University / Aquatic Ecology and Water Quality Management Group

Microplastics have been hypothesized to be a vector for POP transport between organisms and the aquatic environment. Both model and experimental work previously indicated that microplastics might increase body concentrations by up to a factor of two. To enhance comparability with environmental scenarios and validate model simulations, however, additional studies are needed. To date, most plastic exposure studies that involve contaminants use chemicals spiked to the plastics only, whereas in the natural environment, ingestion of regular food items may represent an equally or more important pathway of uptake. Therefore, the relative role of plastic ingestion as an exposure pathway to marine organisms is unknown. Here we use a novel set-up that allows to distinguish between plastic and regular food-mediated transfer of PCBs, by applying matched PCB congener couples in plastic and food respectively. In this set-up, the marine lugworm *Arenicola marina* was exposed to 10-180 polyethylene microplastic and PCBs for 28 days. The endpoints mortality, feeding behaviour and weight as well as PCB concentrations in tissue and sediment were analysed. In this way, more insight was obtained in the effect that microplastics have on the distribution of POPs among compartments.

#### **Calibration of Polydimethylsiloxane and Polyurethane Foam Passive Air Samplers for Measuring Indoor SVOCs**

J.O. Okeme, University of Toronto / Physical and Environmental Sciences; A. Saini, University of Toronto / Department of Physical and Environmental Sciences; C. Yang, University of Toronto / Department Earth Science; L.M. Jantunen, Environment Canada; M.L. Diamond, University of Toronto / Department of Earth Sciences

Passive air sampling has become a popular and efficient alternative to active air sampling for semi-volatile organic compounds (SVOCs). Polyurethane (PUF), styrene divinyl-benzene copolymer (XAD), and polymer coated glass (POG) passive air samplers (PASs) have been well characterized for measuring SVOCs. These methods work well outdoors but are not well characterized for the indoor environment. We introduce a new passive air sampler (PAS) consisting of polydimethylsiloxane (PDMS). PDMS has been used for the passive sampling of SVOCs in water, but has yet to be characterized for passive sampling these chemicals in air. The advantage of using PDMS is its applicability to a wider range of compounds than polyurethane foam (PUF), it is easier to handle than styrene divinyl-benzene copolymer (XAD), and it is unobtrusive for indoor deployment. This research presents chemical uptake kinetics of PDMS and PUF for passive sampling of SVOCs in indoor air in the context of occupational, environmental health and safety (OEHS). Calibration studies were conducted to derive passive air sampling rates and to estimate equilibration times and sampler-air partition coefficients for chemicals. An 8-week long indoor air calibration study for PDMS and PUF disk samplers was conducted from August to September 2013. The experiment was repeated during the same period in 2014 using a larger PDMS. Following strict quality assurance and quality control protocols, all samples from the both studies were extracted and analyzed for polybrominated diphenyl ethers (PBDEs), novel flame retardants (NFRs), phthalates, polycyclic aromatic hydrocarbons (PAHs), and organophosphate esters (OPEs), by gas chromatography-mass spectrometry (GC-MS). Results suggest that the designs of PDMS and PUF samplers are suitable for deployment indoors for a month for the range of chemicals investigated, with the exception of ATE. PDMS sampling rates for NFRs varied from 1.09 m<sup>3</sup>/day/dm<sup>2</sup> (PBT) to 2.01 (ATE) while that of partially sheltered PUF was 1.23 m<sup>3</sup>/day/dm<sup>2</sup> (PBBZ and PBT). For PBDEs, sampling rates of 0.65 (BDE-71) to 1.01 m<sup>3</sup>/day/dm<sup>2</sup> (BDE-66) were calculated for PDMS while those for partially sheltered PUF ranged from 0.88 (BDE-17) to 0.99 m<sup>3</sup>/day/dm<sup>2</sup> (BDE-99). Sampling rates of PDMS and partially sheltered PUF PAS are in reasonable agreement; however, they were typically 2 to 3 times higher than those of fully sheltered PUFs measured in this study and the literature.

274

#### **Passive sampling as a screening tool in Ireland for new and emerging chemicals**

L. Jones, Dublin City University / Chemical Sciences; J. Ronan, Dublin City University; B. McHugh, E. McGovern, Marine Institute; f. Regan, Dublin City University / Chemical Sciences

The impact of this study may lie in the establishment of a capability to utilise passive sampling in the monitoring programme in Ireland for WFD. This project pilots the use of passive sampling technology combined with biota monitoring to assess the presence of priority substances in Irish surface waters. The project focuses in particular on new pollutants earmarked as candidates for the Annex X priority substances list under the EU Water Framework Directive (2000/60/EC) e.g. E2 and EE2, pharmaceuticals, pesticides, PFOS etc. This considers the implications for compliance with current and proposed EQS and investigates the potential for incorporating passive sampling and biota testing in future compliance, investigative and trend monitoring. Results of water, biota and passive sampling will be presented together for samples collected in the Dublin catchment. A separate study

on the occurrence of the pyrethroid pesticide cypermethrin was also conducted. Several sites along the River Liffey, Dublin, were sampled for pharmaceutical as well as other organic pollutants. A POCIS device was deployed at each location and water samples were collected at T-0 and T-end. There are a number of potential point sources of pollution to this catchment with 3 wastewater treatment plants in the area. Pyrethroids have a low toxicity relative to other pesticides (specifically the organochlorines) so have recently been used in place of more toxic pesticides. Cypermethrin has been shown to accumulate in passive sampling devices. This study involved collection of water samples alongside PDMS and SPMD samplers. Cypermethrin was detected in high levels in the water and PDMS samplers. Passive sampling devices can be a useful supporting technique in a 'toolbox' for monitoring within the WFD and other environmental programs. From the investigation of work to date it is clear that passive sampling can play an important role in screening of waters for emerging contaminants, especially for hydrophobic substances where they could be incorporated into a risk based approach to monitoring. Also, passive sampling has demonstrated that it has a role to play in trend monitoring to illustrate where waters are improving in quality over time, thereby offering the WFD monitoring programme a valuable tool.

## 275

### **Passive air sampling of semi-volatile hydrocarbons using polyethylene strips: Mass transfer analysis and calibration with performance reference compounds**

P. Grathwohl, Uni Tübingen / Center of Applied Geosciences; A. Akindutire, University of Tübingen; B. Beckingham, College of Charleston / Environmental Geosciences

Polyethylene (PE) is a promising material for passive air sampling of many organic pollutants, yet sufficient understanding of mass transfer kinetics is required. In this study, 50 µm-thick PE strips spiked with performance reference compounds (PRCs) were deployed indoors (without wind protection) and outdoors (in winter and spring without and with wind protection, respectively). The loss of deuterated fluorene (d-FLU) PRC was fitted with the double film diffusion model to calibrate the air-side boundary layer thickness (1.4 mm for unshielded and 3.3 mm for shielded deployments). Losses of higher molecular weight PRCs (deuterated pyrene and benzo-a-anthracene) were very low but they could reasonably be predicted by the calibrated model. Uptake of polycyclic aromatic hydrocarbons from the atmosphere could be predicted very well while the model yields their concentration in gas phase. Low molecular weight PAHs (e.g. naphthalene) equilibrated in a few hours, whereas the equilibration of the high molecular weight PAHs (e.g. pyrene), was mostly less than 0.1% at the end of deployments (2 weeks) with robust uptake data that integrated concentration and environmental parameters fluctuations. Using the appropriate uptake model allows us to use just one PRC which is particularly beneficial in terms of cost and ease of measurement when uptake to PE is air-side controlled. Models applied here to PAHs can be also transferred to other semi-volatile (emerging) compounds and they allow to calculate the time interval over which the sampler equilibrates, which is a function of their polymer/air partition coefficients (which is strongly correlated to their vapour pressures).

## 276

### **Silicone-based passive samplers for monitoring hydrophobic emerging contaminants in the marine environment: calibration and field application**

m. Pintado-Herrera, Universidad de Cádiz (Spain) / Department of Physical Chemistry; I. Allan, Norwegian Institute for Water Research NIVA; E. Gonzalez-Mazo, University of Cadiz / Physical Chemistry; P. Lara-Martin, University of Cadiz (Spain)

There is a growing interest on knowing the concentration and distribution of a large group of new non-regulated organic compounds (emerging contaminants) in the environment, many of them used in consumer goods, such as antimicrobials, fragrances, UV filters or flame retardants. Some of these chemicals present hydrophobic properties, sharing some of them with other regulated compounds (i.e., polycyclic aromatic hydrocarbons, polychlorinated biphenyls) in terms of high octanol-water partition coefficients (K<sub>ow</sub>) and low solubility in water. However, analyzing their freely dissolved concentrations in waters samples is often a difficult task if conventional sampling strategies. In this sense, the use of passive samplers represents a very powerful alternative to estimate aqueous concentration. Moreover, these samplers can provide time-integrated concentrations of the analytes in the environment. In this work, the use of single phase sampler, such as low density polyethylene (LDPE) and silicone rubbers (SR) has been tested. The main objective of this work was to calibrate passive samplers to relate the concentrations of several emerging contaminants in the sampler with their free dissolved concentrations in water for some emerging compounds. In this regard, laboratory experiments were performed to establish diffusion, since the transport of analytes from the water to the passive sampler is diffusion-controlled and sampler-water partition coefficients, both are needed to estimate the dissolved concentration of any analyte. Later, SR samplers were chosen and deployed during one year at several sampling stations located within the Bay of Cadiz (SW Spain). In accordance with the results obtained of the laboratory experiments, in general the diffusion coefficient decreased when molecular weight increased. After determining K<sub>pw</sub> values, we observed that most of the analytes were positively correlated either with the molecular weight (R<sup>2</sup> > 0.85). In conclusion, molecular

weight is considered a better estimator of log K<sub>pw</sub>. Finally, a sampling campaign was carried out in the Bay of Cadiz (SW of Spain). Passive sampling data from this monitoring was compared to those obtained from spot samples collected at the same locations with amber glass bottles. Levels of some fragrances (i.e. OTNE) and UV filters (i.e. octocrylene) were predominant over other emerging and regulated contaminants. Seasonal variations were observed for some UV filters (i.e. EHMC and homosalate).

## 277

### **Determination of PDMS-water partition coefficients of super-hydrophobic PBTs using empirical maximum solubility**

V.J. Schacht, National Research Centre for Environmental Toxicology Entox; S. Grant, The University of Queensland / National Research Centre for Environmental Toxicology Entox; B.I. Escher, Helmholtz Centre for Environmental Research GmbH - UFZ / Cell Toxicology; D. Hawker, Griffith University / School of Environment; C. Gaus, National Res. Centre for Environmental Toxicology / Public Health Department

Freely dissolved concentrations (C<sub>free</sub>) of contaminants in environmental samples, which are relevant for bioaccumulation and toxicity, are widely determined using solid phase microextraction (SPME). The nonpolar polymer PDMS is typically used for passive sampling of persistent, bioaccumulative, toxic compounds (PBTs). PBT concentrations in an exposed PDMS SPME fibre at equilibrium are related to C<sub>free</sub> via the PDMS-water partition coefficient (K<sub>PDMS-w</sub>). However, for super-hydrophobic PBTs (log K<sub>ow</sub>>7), many of which can be highly toxic e.g. dibenzo-p-dioxins (PCDDs), determining K<sub>PDMS-w</sub> is very challenging due to their extreme hydrophobicity and long equilibration times. Consequently, reported K<sub>PDMS-w</sub> are often highly variable or not available and new approaches to reliably estimate these values are needed. Therefore, an approach to measure super-hydrophobic PBT maximum solubility in PDMS (SPDMS) was developed and K<sub>PDMS-w</sub> estimates for PCDDs were derived from experimentally determined SPDMS and literature values for maximum water solubility. Measuring SPDMS was performed by partitioning PCDDs between super-saturated PDMS sheets and clean PDMS fibres. Providing sufficient excess solute is loaded into the sheets, the equilibrium concentration in the clean fibres is at maximum solubility. Super-saturation was achieved by swelling the PDMS sheets in solutions of PCDDs in toluene at high concentrations (magnitudes higher than the PCDD expected solubility in PDMS). During swelling analytes are transported into the PDMS where they remain after the solvent is evaporated. Clean PDMS fibres were sandwiched between the loaded sheets and replicates of fibres (n=3-5) were removed from the sheets after different time points, extracted in hexane and quantified on a GC-ECD. SPDMS ranged over an order of magnitude (19 µg/ml 123478-HxCDD, 9.5 µg/ml 1234678-HpCDD, 1.9 µg/ml OCDD), with increasing solubility with decreasing congener hydrophobicity. Identical values for congeners loaded as mixtures or individually were obtained. Solubility-based K<sub>PDMS-w</sub> values were consistently higher than previous experimentally determined values and show a clear correlation with log K<sub>ow</sub> with a slope close to 1. This relationship is consistent with K<sub>PDMS-w</sub> for compounds with log K<sub>ow</sub>< , suggesting improved accuracy compared to traditional experimental methods. The new approach provides a simple, rapid (

## 278

### **Air-water exchange, spatial and temporal trends of POPs in air and water of the Great Lakes using polyethylene samplers**

R. Lohmann, University of Rhode Island / Graduate School of Oceanography; Y. Liu, Environmental Sciences; P.A. Helm, Ontario Ministry of the Environment & Climate Change / Environmental Monitoring and Reporting Branch; M. Khairy, URI; D.C. Muir, Environment Canada / Aquatic Contaminants Research Division

Polyethylene passive samplers were deployed during 2011 and 2013 in the lower Great Lakes to assess the spatial distribution and sources of gaseous and freely dissolved polychlorinated biphenyls (PCBs) and organochlorine pesticides (OCPs) and their air-water exchange. In the water, dissolved concentrations of the ICES 7 PCBs along the US shore were greater than those on the Canadian site in 2012. Sum 7 PCBs ranged from 3 µg/L in the open Lake Erie to over 40 µg/L for sites along the Canadian shore of Lake Ontario – Rochester and the outflow of the Niagara River. The distribution of dissolved PCB was related to the presence of waste water treatment plants and urban centers along the US coast, while there was no obvious correlation to either waste water treatment plants or population density along the Canadian shore. Gas-phase concentrations of PCBs ranged from < 10 µg/m<sup>3</sup> to greater 300 µg/m<sup>3</sup>. The distribution of gas-phase PCBs differed significantly from that in the water, probably indicating that there are different sources contributing to either phase. Along Lake Erie, gas-phase concentrations were greatest in the urban area of Cleveland, and lowest at the open Lake, while concentrations in Lake Ontario were dominated by elevated concentrations at Cape Vincent. Air-water exchange gradients indicate net volatilization across most sites and seasons.

## **Monitoring and modelling-based approaches for identification and prioritisation of hazardous emerging pollutants in European freshwater resources (II)**

## Data-driven prioritizing of relevant chemicals for various water types using suspect screening LC-HRMS

R.M. Sjerps, A. van Wezel, KWR Watercycle Research Institute / Chemical Water Quality and Health

We developed a suspect screening based system in order to prioritize large numbers of compounds for their possible human health relevance towards (drinking) water. We based the suspect list on a large number of chemicals authorized on the European market, via various regulations and including hardly studied compounds. This list was applied to a large number of water samples, including effluents, surface waters, groundwaters and drinking waters. We included a TTC based threshold to prioritize the most relevant chemicals that were encountered. The prioritized compounds were compared to the compounds occurring on existing priority lists and to compounds regulated in water quality legislation. Included in the list are chemicals registered under the REACH legislation as well as substances of very high concern (SVHC), chemicals authorized under the Plant Protection Products Regulation and Biocidal Product Regulation and pharmaceuticals and veterinary pharmaceuticals. Mixtures, anorganic, metaloids and non-ionizable compounds were excluded from the list. Only compounds containing N, S, O, or P are considered. The 151 water samples (2007-2014) were well distributed over the Netherlands, and comprised 20 drinking waters, 39 groundwaters, 73 surface waters and 19 effluents. The method provided a fingerprint of prioritized chemicals per water sample and water type. The suspect list covered 5219 individual chemicals. In total 158 masses and 243 suspects in the combined data for positive and negative ionization mode matched with the LC-HRMS data above the threshold for the various water types, less than 5% of all chemicals in the suspect list. Most of the prioritized suspects are registered chemicals within REACH. Of the 44 compounds that occur in water quality regulations, only one suspect was prioritized. Of the substances on NORMAN or IAWR/RIWA attention lists and were included in the suspect list, respectively 7.5% and 23.5% were prioritized suspects. This emphasizes the complementarity of the suspect screening approach, in spite of the uncertainties, as compared to the more commonly used target analysis approach. A decrease in summed concentration in terms of IS-equivalents was observed from effluent, to surface water, groundwater and drinking water. A significant decrease can be observed in retention time from effluent towards drinking water, confirming that more polar compounds occur in drinking water.

### Bioassay-assisted identification and prioritization of toxicity drivers in the Danube River

K. Tollefsen, NIVA / Ecotoxicology and Risk Assessment; T. Gomes, Norwegian Institute for Water Research (NIVA); K. Petersen, Norwegian Institute for Water Research; A.R. Almeida, University of Aveiro / Biology; T. Høgåsen, Norwegian School of Veterinary Science (NSVS); M. Krauss, T. Schulze, Helmholtz centre for environmental research - UFZ / EffectDirected Analysis; W. Busch, Helmholtz centre for environmental research - UFZ / Bioanalytical Ecotoxicology; T. Williams, University of Birmingham / School of Biosciences; P. Antczak, University of Liverpool; Z. Rabova, Masaryk University / Faculty of Science RECETOX; J. Slobodnik, Environmental Institute; J. Chipman, The University of Birmingham / School of Biosciences; P. Thomas, CEHTRA SAS / Ecotoxicology and Risk Assessment; R. Altenburger, UFC Centre for Environmental Research / Department of Bioanalytical Ecotoxicology

Surface waters contain complex mixtures of inorganic and organic pollutants that may affect the health of humans and wildlife. As the composition of these complex mixtures are highly variable, assessment of their hazard and risk are often poorly characterized. Efforts to develop a standardized approach to identify individual and cumulative impact of pollutants on organisms are highly warranted. The present work aimed to develop a conceptual approach to 1) identify toxicity drivers to aquatic organisms, 2) provide in-depth knowledge about the Mode of Action (MoA) of key pollutants, 3) identify compounds that may cause combined toxicity in mixtures, 4) formulate a strategy for optimal use of bioassays to characterize the hazard associated with key pollutants and 5) provide linkage to mechanistically-based hazard/risk assessment approaches. This approach will link the existing exposure information from the Danube River (Joint Danube Survey 3, JDS3) to experimental effect data for algae, crustaceans and fish for subsequent identification of toxicity drivers towards one or more aquatic species. All chemicals where subsequently categorized according to chemical group and MoA information to identify suitable bioassays that can be used for biomonitoring purposes. Suitable batteries of bioassays were thereafter used to screen the toxicity potential in large volume solid Phase extraction (LVSP) extracts and results compared to predicted hazard/risk quotients. The final part of the work focussed on developing approaches for how to link the available data to concepts such as Adverse Outcome Pathways to support linking chemical and bioassay data to more mechanistically-based hazard (risk) assessment frameworks and aid lab to field extrapolations. Special emphasis were given the identification of ecologically-relevant reference compounds for use in experimental efforts with high-throughput (e.g. in vitro assays) and multi-trophic bioassays (e.g. algae, crustaceans and fish). This approach represent the initial step in a process to design optimal experimental approaches to decipher complex chemical interactions associated with combined toxicity, and improve bioassay screening approaches in environmental monitoring of European surface waters.

## 281

### Which chemicals show effects in cell-based in-vitro bioassays? - Are we monitoring the right chemicals?

B.I. Escher, Helmholtz Centre for Environmental Research GmbH - UFZ / Cell Toxicology; J.Y. Tang, The University of Queensland / ENTOX; F. Busetti, J. Charrois, Curtin University / Curtin Water Quality Research Centre

Bioanalytical tools have been applied for monitoring of water quality worldwide for several decades. Most research has focused on surface waters and domestic and industrial wastewaters. In recent years, screening of wastewater and advanced water treatment processes, disinfected drinking water and recreational waters have emerged. Cell-based assays can either assess general cytotoxicity or target a specific mode of toxic action or step of the toxicity pathway. Comprehensive risk assessment thus requires a battery of bioassays to cover a range of modes of action and/or toxicity pathways relevant for the water sample to be tested. The goal of this study was to understand which fraction of effect observed in cell-based bioassays can be explained by known chemicals. The answer to this question will be important when deciding whether bioassays are required for water quality monitoring or if the regulated and regularly monitored chemicals are sufficient to assure water quality. For the "iceberg experiments" we mixed the detected chemicals and tested the designed mixtures in bioassays, then compared the results with the biological responses from wastewater treatment plant effluent, treated and recycled water. The results of this study have shown that there is no clear answer to the question of how much of the biological effect can be explained by known chemicals but that it depends on the type of effect. For receptor-mediated modes of action, the majority of the responsive chemicals have been identified, in this study for herbicides and in a previous work for estrogenic chemicals. For more integrative endpoints, such as the oxidative stress response and cytotoxicity, there remain many unknowns and bioassays are clearly needed to get a full picture of the effects of micropollutants.

## 282

### Development of a miniaturized AMES assay for high-throughput effect-directed analysis of water samples using microfractionation

N. Zwart, Institute for Environmental Studies; T. Hamers, VU University Amsterdam, Institute for Environmental Studies (IVM) / Institute for Environmental Studies; W. Jonker, VU University / BioMolecular Analysis group; C.J. Houtman, The Water Laboratory; J. de Boer, VU University / IVM; J. Kool, VU University / BioMolecular Analysis group; M. Lamoree, VU University, Institute for Environmental Studies / Institute for Environmental Studies

One of the classical toxicological endpoints in analysis of surface water and drinking water is mutagenicity. After its development, the salmonella reversion based AMES test quickly became the most widely used method for the determination of the mutagenic potential of compounds and samples. Efforts to keep track of the release of mutagens into the environment and to monitor the processes of drinking water purification depend on the ability to determine the presence of these compounds in surface, ground and effluent water. The application of bioassays like the AMES test together with chemical analysis methods in effect-directed analysis (EDA) provides a strategy to detect and identify novel mutagenic compounds. However, for rapid toxicity assessment of e.g. water samples, EDA suffers from lack of throughput and is regarded as a laborious, time consuming method. To achieve faster analysis and higher-resolution separation, a high throughput-EDA (HT-EDA) method was developed that combines 384-well plate, UPLC based, microfractionation with a miniaturized AMES assay. The applicability of the miniaturized assay will be demonstrated by analysis of selected surface, ground and waste water samples. This application of high-resolution microfractionation together with miniaturized bioassays will open the way to HT-EDA and will emphasize the advantages of the combined methodology of chemical analysis and bioassays in the analysis of environmental samples, including drinking water.

## 283

### Sulfonamide Transformation Products: Formation, Analysis and Residual Antibacterial Activity

M. Majewsky, Karlsruhe Institute of Technology (KIT) / Engler Bunte Institut Chair of Water Chemistry and Water Technology; H. Horn, Karlsruhe Institute of Technology KIT / Chair of Water Chemistry and Water Technology

Sulfa drugs are widely used in human and veterinary medicine and ubiquitously detected in the aquatic environment. There is increasing concern regarding their potential to alter the composition of environmental bacterial communities and the possible promotion of antibiotic resistance. While the fate and occurrence of the parent sulfonamides received increased attention during the last decade, their transformation products (TPs) only now shift into the focus of environmental risk assessment. Some selected sulfonamide TPs have already been detected in wastewater and surface water alike. However, considering that numerous laboratory studies reported the formation of a variety of TPs, it can be expected that many more sulfonamide TPs occur in the aquatic environment. For the most prominent short-acting human sulfonamide antibiotic sulfamethoxazole (SMX), there are currently more than 20 first daughter TPs known to directly originate from photolysis or biodegradation. SMX certainly is among the best studied sulfonamide antibiotics. Although most likely not all biotic and abiotic transformation reactions reported for SMX are necessarily valid for other sulfonamides, there is much to

suggest that the homologous structure of other sulfonamides exhibit the same reactive sites and thus undergo the same or similar transformations. Therefore, this study presents a data set of more than 20 SMX TPs aiming at identifying the transformation reactions such as acetylation, hydroxylation, nitration or deamination. The elucidation of the product ion spectra during MS/MS experiments allowed for a qualitative determination of suspected TPs for both SMX and of sulfonamide homologues in monitoring and degradation studies. Examples from photolysis and biodegradation are presented. Two new metabolites have been confirmed via synthesized standards. Some of the TPs still contain a pharmacophore-like moiety, and some derivatives incorporate almost the complete SMX parent compound structure. As a consequence, 11 TPs of SMX formed during human metabolism, microbial biodegradation, photolysis, and hydrolysis were tested for their residual antibacterial activity using bacterial growth and luminescence inhibition assays. Results show that derivative TPs clearly exhibit antibacterial activity while compound cleavage leads to the loss of this mechanism of action. The acetylated derivatives retain however less than 10% of the effect of SMX on growth and luminescence inhibition.

## Nanoparticle (NP) speciation and its consequences for NP environmental fate and effects (II)

284

### Effects of multigeneration exposure of pristine and sulfidised silver nanoparticles on *C. elegans* and potential recovery

C. Schultz, Centre for Ecology and Hydrology; A. Wamuch, University of Kentucky; O.V. Tsyusko, University of Kentucky / Department of Plant Soil Sciences; J.M. Unrine, University of Kentucky; C. Svendsen, CEH, Wallingford / Pollution and Ecotoxicology; D. Spurgeon, Centre for Ecology & Hydrology. As research on the hazard assessment of nanomaterials advances it has become clear that to address their environmental impact toxicity testing needs to go beyond standardised laboratory test and include more environmentally realistic exposure scenarios. To gain a better understanding of their environmental impact experimental designs should aim to include exposure relevant transformed materials as well as long-term exposures to investigate the long-term and transgenerational effects that can occur for some recalcitrant nanomaterials and continual input. In this study potential changes in sensitivity of nematodes to silver ions ( $\text{AgNO}_3$ ), pristine (70 nm, PVP coated) and artificially aged (76 nm,  $\text{Ag}_2\text{S}$ ) silver nanoparticles on the growth, reproduction and lifespan of the soil dwelling nematode *Caenorhabditis elegans* is studied following exposure over multiple generations (0, 2, 5, and 10) and potential recovery of adverse effects on cessation of exposure. Exposure concentrations for the continuous exposures are based on the reproductive  $\text{EC}_{30}$  for  $\text{AgNO}_3$  and Ag-PVP:  $\text{AgNO}_3 = 0.15 \text{ mg/l}$ , Ag-PVP =  $1.5 \text{ mg/l}$ ,  $\text{Ag}_2\text{S} = 15 \text{ mg/l}$ . Preliminary data analysis showed considerable differences in toxicity between ionic silver and the two silver nanoparticles of  $\text{AgNO}_3 > \text{Ag-PVP} > \text{Ag}_2\text{S}$ . Further initial results showed effects of chronic exposure on the lifespan for  $\text{AgNO}_3$  at  $2.4 \text{ mg/l}$  with lifespans decreasing from  $17 \pm 1$  days in the parent to  $8 \pm 2$  days in the second offspring generation. Such effects on life-span were not observed for the other treatments. Multi-generational exposure indicated that in the parent generation, there was no significant difference in size between controls and the highest doses ( $\text{AgNO}_3 = 2.4 \text{ mg/l}$ , Ag-PVP =  $24 \text{ mg/l}$ ,  $\text{Ag}_2\text{S} = 120 \text{ mg/l}$ ) 48 hours after hatching. However, by generation 5, growth and body size showed high sensitivity, such that both were adversely affected by the highest Ag doses. Overall there appears to be an increase in sensitivity over the tested generations, however, this has yet to be confirmed with further data analysis as well as for subsequent generations.

285

### Effects of ageing and soil properties on the bioavailability of Zn nanoparticles to *Eisenia andrei*

A. Romero, UGR (CIF Q1818002F) / edafologia y quimica agricola; F.M. Peinado, University of Granada / edafologia y quimica agricola; C. van Gestel, VU University Amsterdam / Ecological Science. Zinc oxide (ZnO) is one of the most commonly used types of metal-based nanoparticles (NP) which enter the environment with soil being one of the main sinks. In ecotoxicological assays, exposure of earthworms to ZnO NPs and  $\text{ZnCl}_2$  resulted in a similar uptake and internal distribution of Zn, suggesting bioavailability of these NPs. Moreover differences in zinc bioavailability between aged and freshly spiked soils depend on soil properties. Long-term processes (ageing) could reduce ZnO NP bioavailability and toxicity, but it remains unclear if this is due to changes in soil pH or in Zn NP dissolution. It is essential to study the conditions and contribution of NPs to the long-term toxicity of ZnO NPs in terrestrial environments. For that the aim of this study is determine the availability of ZnO NPs and the influence of ageing on the Zn toxicity to *E. andrei*, in soils with different physicochemical properties. Three soils with contrasting properties were spiked with ZnO NPs (concentrations close to the  $\text{EC}_{10}$  and  $\text{EC}_{50}$ ) and  $\text{ZnCl}_2$  ( $\text{EC}_{50}$ ). Soils were moistened and incubated for 196 days under controlled conditions (ageing). At different time points, available Zn levels in the soils were determined by extraction with 0.1M copper nitrate ( $(\text{CuNO}_3)_2 \cdot 3\text{H}_2\text{O}$ ) and pore water analysis. Earthworm toxicity tests (OECD, 2004) were performed with survival, weight change and reproduction as the endpoints. Zn concentrations in the copper nitrate extracts (ZnCu), pore water (ZnPW) and in earthworm tissues (ZnE) were

measured by ICP-MS. Results showed that soil pH values decreased upon addition of  $\text{ZnCl}_2$ , while it was increased by the addition of ZnO NPs. Copper nitrate extracted almost all the zinc (available Zn), while Zn concentration in PW was lower than 17% of the Zn added. The highest available Zn levels were found in soils spiked with  $\text{ZnCl}_2$ . In general, extractable Zn levels significantly decreased with ageing of the soils, for both  $\text{ZnCl}_2$  and ZnO NPs. The lowest available Zn levels were found in the alkaline soil. Earthworm reproduction was most affected by  $\text{ZnCl}_2$  due to its highly bioavailable and soluble ionic Zn form. Reduction compared to controls showed a different behaviour depending on the test soil for the different ageing periods suggesting that Zn bioavailability (and toxicity) is dependent on ageing and soil properties. Further analyses of the data are needed to relate toxicity and soils properties in order to assess the risk of nanoparticles over time.

286

### Speciation matters--Bioavailability of silver and silver sulfide nanoparticles to alfalfa (*Medicago sativa*)

J. Stegemeier, Carnegie Mellon University / Civil and Environmental Engineering; F. Schwab, Duke University / Civil Environmental Engineering CEINT; B.P. Colman, Duke University; E. Bernhardt, Duke University / Biology; M. Wiesner, Duke University; G. Lowry, Carnegie Mellon University. Silver nanoparticles (nano-Ag(0)) are incorporated into consumer products which leads to an increased demand to understand the environmental fate of nano-Ag(0) and their important environmentally-transformed analog, silver sulfide nanoparticles (nano- $\text{Ag}_2\text{S}$ ). Nano Ag(0) and nano- $\text{Ag}_2\text{S}$  in waste water treatment plant biosolids applied as fertilizer to agricultural soils provide an exposure route for terrestrial and aquatic plants. In the present study, the uptake of silver into alfalfa (*Medicago sativa*) plants was quantified and visualized upon hydroponic exposure to a suspension of nano-Ag(0), nano- $\text{Ag}_2\text{S}$ , and as a control, a silver ions solution ( $\text{Ag}^+$ ). The total silver uptake was determined in dried roots and shoots, and the spatial distribution of silver was investigated using microscopy and synchrotron-based X-ray imaging techniques. Both nano-Ag(0) and nano- $\text{Ag}_2\text{S}$  were bioavailable in the root systems and exhibited limited translocation of silver into the shoot system. X-Ray fluorescence (XRF) mapping suggests that the mechanism of silver uptake for nano-Ag(0) is similar to the mechanism for dissolved silver ions. Alternatively, the nano- $\text{Ag}_2\text{S}$  was found to adhere to the exterior of the root with limited incorporation into the root tissue, and was associated with the formation of nano- $\text{SiO}_2$  particles (phytoliths) in the cytoplasm of these plants. The overall phytoavailability and capacity of the nano- $\text{Ag}_2\text{S}$  to translocate throughout the plants remains similar to the pristine nano-Ag(0), despite lower silver ion concentrations associated with the less soluble  $\text{Ag}_2\text{S}$  particles.

287

### Using surface modified CdTeS/ZnS nanocrystals (QDs) as nanotracers in complex waste matrices

F. Part, University of Natural Resources and Life Sciences, Vienna / Department of Water Atmosphere Environment WAU; C. Zaba, University of Natural Resources and Life Sciences Vienna / Department of Nanobiotechnology DNBT Institute for Synthetic Bioarchitectures; M. Oberwalder, University of Natural Resources and Life Sciences Vienna / Department of Chemistry DCH Division of Analytical Chemistry DCHAC; M. Huber-Humer, University of Natural Resources and Life Sciences Vienna / Department of Water Atmosphere Environment WAU Institute of Waste Management ABFBOKU; E.K. Sinner, University of Natural Resources and Life Sciences Vienna / Department of Nanobiotechnology DNBT Institute for Synthetic Bioarchitectures. Engineered nanomaterials (ENMs), such as nano- $\text{TiO}_2$ ,  $-\text{SiO}_2$ , carbon nanotubes, fullerenes, Quantum Dots (QDs), are already applied in many consumer products. The area of applications ranges from cosmetics, construction materials and to electronic equipment. In the future, the variety and production volumes of ENMs can only be expected to increase. CdSe, CdTe or InP QDs, are used for their semi-conducting and fluorescence properties in thin solar cells and LED background lightings. Surface modified QDs are utilized as fluorophores and biomarkers in medical applications. In order to improve the performance of QDs and add desirable properties they can be surface modified. E.g., the photoluminescence quantum yield of QDs can be enhanced by reducing surface defects using ZnS or CdS shells. A variety of surface modifications influences bioavailability – e.g. by using N-acetyl-L-cysteine (NAC). Carboxyl functionalised groups lead to a higher surface charge and may increase cellular QD uptake. In general, more research is needed to assess the eco-toxicological effects of QDs. Our project shows the potential of QDs to be used as nanotracers for studies about the fate and behaviour of ENMs in complex matrices, such as liquid waste samples. In this study we synthesised QDs and modified them with carboxy-terminated coatings. QDs were characterised by using dynamic light scattering (DLS), transmission electron microscopy (TEM) and inductively coupled plasma mass spectroscopy (ICP-MS). These nanotracers were spiked to landfill leachates, one potential QD source. The complex leachate matrix, containing QDs, was screened by ICP-MS and fluorescence analysis.

### The bioavailability and toxicity of nanoparticles in biosolids to earthworms

E. Lahive, Centre for Ecology & Hydrology (NERC); M. Matzke, Centre for Ecology & Hydrology (NERC) / Molecular Ecotoxicology; A. Romero, UGR (CIF

Q1818002F) / edafologia y química agrícola; A.A. Horton, A. Lawlor, Centre for Ecology and Hydrology; D. Spurgeon, Centre for Ecology & Hydrology; C. Svendsen, CEH, Wallingford / Pollution and Ecotoxicology; S. Lofts, Centre for Ecology & Hydrology / Shore Section

One of the main release pathways of nanoparticles (NPs) to terrestrial ecosystems is through the application of biosolids from waste water treatment plants (WWTP) to agricultural land. NPs will undergo transformations such as sulfidation and phosphatisation in WWTP, dramatically altering their properties. This study investigates the bioavailability of NPs (ZnO, Ag and TiO<sub>2</sub>) contained in biosolids to the earthworm *Eisenia fetida*. Biosolids were generated from a purpose-built, pilot scale waste water treatment plant (WWTP) where contaminants (i.e. metal salts or NPs) had been added to the plant influent. The WWTP consisted of three parallel lines which enabled the same influent to be spiked with metal salts, NPs or unspiked to produce a control sludge. The biosolids produced were mixed with agricultural topsoil (Woburn, UK) to obtain a final biosolids content of 42% in the mixed material. Earthworms were exposed to this mixed material (*fresh biosolids exposures*) and to the same biosolids mixtures which had been aged in outdoor mesocosms for six months (*aged biosolids exposures*) in different application scenarios: *a*) worst case scenario of ten years of annual application (i.e. 42% biosolids), *b*) application once every three years (17%) and *c*) application once every ten years (5%) (only fresh biosolids exposures). Effects on earthworm reproduction and total metal body concentrations were measured. Pore waters were extracted from all soils and pH, total dissolved carbon (DOC) and total metal concentrations measured. All exposure soils were also sampled for community fingerprinting using TRFLP analysis. The application of fresh NP and metal salt biosolids representing one in three years reduced earthworm reproduction by 96% and 33.4%, respectively, compared to the control biosolids. The aged biosolid exposures were less toxic than the fresh biosolids, although aged NP biosolids did cause a greater reduction in earthworm reproduction than the aged metal salts biosolids. In this study it was seen that NPs in biosolids from WWTP had a greater effect on earthworm reproduction than biosolids with metal salts. The reasons for these observations are likely to depend upon the NP and metal transformations that occur in WWTP and how such transformations influence the speciation and bioavailability of the materials in the final products.

289

#### Effect of biosolids on nAg speciation and toxicity to plants

H.V. McShane, McGill University / Dept of Natural Resource Sciences; D.M. Schwertfeger, McGill University / Biological Assessment and Standardization Division; W.H. Hendershot, McGill University / Dept of Natural Resource Sciences

Nano-sized Ag (nAg) is expected to be released into waste water systems in increasing concentrations, from where it may be applied to agricultural land in biosolids. While a number of studies have investigated the effects of nAg on aquatic organisms, few have investigated its effects on organisms when applied to soils in biosolids. In this study, nAg was mixed with biosolids (nAg+bs), which were then added to soils. Barley growth was not reduced in biosolid-amended soils, whereas growth in soils directly amended with either nAg or Ag(NO<sub>3</sub>) decreased with increasing total soil Ag. Soil speciation studies demonstrated that Ag ion activity was low in soils amended with nAg+bs, suggesting that toxicity was related to Ag<sup>+</sup> ion release.

## Delving into the planetary boundary concept and issues related to biodiversity and natural resources use in LCA (II)

**Material supply opportunity as a new perspective to address the "criticality" issue from a developing countries context: the case of Chile and South Africa**  
C. Pena, Addere / Sustainability; K.G. Harding, Industrial and Mining Water Research Unit School of Chemical and Metallurgical Engineering; G. Sonnemann, University of Bordeaux 1 / The Life Cycle Group CyVi; E.D. Gemechu, University of Bordeaux

A definition of resource criticality is the risk associated with the supply of minerals due to the potential limit to their accessibility because of geological, social and geopolitical factors. This addresses the resources issue from a consumption perspective. There is growing interest from developed countries to be engaged in criticality assessment to identify the most relevant resources. Emerging regions, including Africa and Latin America, possess major reserves of minerals. Many of the critical materials are present in the mineral reserves of these regions. Therefore, these regions have strategic importance in terms of the supply of the materials needed for technology related to defense and high tech applications. We must consider the sustainability of these materials from a supply and accessibility viewpoint and not just as seen from developed countries. Therefore, the main aim of this work will be to provide a conceptual framework to assess the supply opportunity for developing countries from "critical resources". A new perspective that addresses the resource issue from a production perspective, to be called Material supply opportunity, is proposed in this work. The proposed framework has four main elements: resource screening (assesses the most relevant indicators from existing criticality assessment methods), resource analysis (identifies from the determined critical resources that are produced), context analysis (the situation in

South Africa and Chile with regard to the critical resources) and material supply opportunity strategy (proposes a strategy). Chile is a mining country rich in mineral reserves. It has the world's largest reserves, and is the largest producer, of copper. It also has significant reserves of lithium, rhenium, iodine, molybdenum, natural nitrates, silver and gold. Silver and gold have been produced directly from gold mines and associated to copper production. Recently rare earth deposits were identified and exploration studies are being carrying out. South Africa is typically known for its platinum, gold and coal. Further, based on international production, it ranks number one and two for chrome/ferro-chrome, platinum group metals (PGMs), vermiculite and antimony, manganese ore, titanium minerals, vanadium, zirconium respectively. South Africa also ranks as having the highest reserves for chrome ore, fluorspar, manganese and PGMs. There is also a move to start larger exploration and mining of rare earth minerals.

#### From Scarcity to Resource Security Indices: an approach to assess the geopolitical security of resource supply

E. Gemechu, University of Bordeaux / Institute of Molecular Sciences ISM; G. Sonnemann, University of Bordeaux 1 / The Life Cycle Group CyVi

There is an increasing concern among citizens, businesses and governments over the security and sustainable supply of resources mainly due limited availability. The resource challenges are very complex in nature, therefore, assessing the geopolitical resource security and sustainability needs a new perspective and related analytical approaches to cope with it. Life cycle assessment (LCA) has been a standardized approach used to assess the direct impact from the use of resources. For some time now, there has been a discussions within the LCA community on how the resource issue to be addressed in the current LCA and the need for a broader perspective. The direct impact from the use of resources in LCA is mainly focused on the geological availability, which has a long-term time perspective. Other aspects such as supply chain risks due to short-term geopolitical actions as well as social and economic aspects are not well covered and need to be an integral part of the Life Cycle Sustainability Assessment (LCSA) framework. This could broaden the scope of LCA from an environmental related impact to a resource supply risk assessment tool. In this line of thinking, this paper introduces a new approach, what we call Resource Security Indices. It is based on the Earth Security Index published by the Earth Security Initiative. This paper, hence, focuses on how to assess the geopolitical resource security and sustainability challenges in a new perspective. A conceptual framework that answers the security issue of resources is provided and also applied for selected countries. The proposed Resource Security Indices extend the supply risk due to geopolitical and social factors to a wider dimension of resource security by including other aspects that are unavoidably linked to supply chain disruption. The overall resource security rank will be the reflection of each region's or country's performance in all the indicators taken into account. The introduction of the concept of resource security indices, which encompass different aspects such as water scarcity, energy security and land use change impacts, can help decision makers to better understand the constraints of secure and sustainable supply of resources.

292

#### Setting targets on the environmental footprint of nations using planetary boundaries

R. Frischknecht, S. Buesser, treeze Ltd.; C. Nathani, Ruetter Partner

Domestic environmental impacts may be reduced by outsourcing potentially highly polluting activities, such as heavy industries and agriculture. While such measures or effects may help to fulfil and comply with national environmental targets and policies, outsourcing and maintaining polluting activities abroad does not lead to environmental improvements on a global scale. That is why the development of consumption-based environmental impacts of Switzerland from 1996 to 2011 was quantified. A simplified physical model was used which quantifies domestic environmental impacts, adds environmental impacts related to imports and subtracts environmental impacts related to exports combining foreign trade statistics with life cycle assessment data. Environmental impacts are quantified with the several single score methods such as the Swiss eco-factors 2013 based on the ecological scarcity method and with several midpoint indicators. This presentation focuses on eutrophying impacts of Swiss consumption. Marine eutrophication is quantified based on the amount of nitrogen emitted and reaching marine environments. Consumption-based marine eutrophication impacts increased by 8.5% since 1996 because emissions due to foreign trade increased substantially while domestic emissions showed hardly any decrease. At the same time the share of eutrophying substances emitted abroad increased substantially. Hence, regulating eutrophying substances within the country does not suffice in open economies such as Switzerland. The planetary boundary concept is applied on consumption-based marine eutrophication. The knowledge on consumption-based environmental impacts and its domestic share can be applied on target setting. National reduction targets are applied on the domestic emissions whereas a global planetary boundary is used to define the reduction target for eutrophying substances emitted abroad. It was shown that Swiss consumption-based marine eutrophication of about 118'000 tons of nitrogen equivalents should be reduced by nearly 60%. 30% of the reduction needs to be implemented in Switzerland, the remaining 70% of the required reduction should be achieved abroad.

### Quantifying spatially derived carrying capacity occupation: Framework for characterisation modelling and application to terrestrial acidification

A. Björn, Technical University of Denmark / Department of Management Engineering; M. Margni, Ecole Polytechnique de Montreal / Mathematical and Industrial engineering; p. roy; C. Bulle, CIRAIG - ESG - UQAM / Strategy corporate social responsibility; M. Hauschild, DTU Management Engineering

The popularity of the ecological footprint method and the planetary boundaries concept shows an increasing interest among decision makers in comparing environmental impacts to carrying capacities of natural systems. Recently carrying capacity-based normalisation references were developed for impact categories at midpoint level in LCA. These references are operational and their meaning can easily be communicated to practitioners and decision makers. Yet they do not capture potentially important spatial variations in carrying capacities. To overcome this weakness we propose to integrate carrying capacity in characterisation factors (CFs) as an alternative to using carrying capacity as reference information in normalisation references. We developed a generic mathematical expression for a spatially differentiated CF, which allows expressing impact scores as occupation of carrying capacity in units of km<sup>2</sup>\*year. This metric resembles that of the ecological footprint method and may be compared to the availability of land or water. The framework was applied to the terrestrial acidification impact category. The geochemical steady-state model PROFILE was used to quantify carrying capacities as deposition levels corresponding to an acceptable change of natural pH, at a 2.0x2.5° resolution at the global scale. Carrying capacities were then combined with atmospheric fate factors of acidifying emissions to derive CFs. These were applied to an average emission inventory for the annual electricity consumption of a household in 100 random global locations. To evaluate the consequence of using the CFs in a comparative assessment the 100 impact scores were ranked and compared to the corresponding ranking when using existing CFs based on marginal impacts above carrying capacity on the same inventory. The difference in ranking reflects the different natures of the two sets of CFs: The existing CFs are aligned with consequential thinking and concerned with marginal changes above carrying capacity, while our derived CFs are aligned with attributional thinking and concerned with the occupation of carrying capacity. This work shows the viability of spatially derived absolute sustainability assessment, i.e. assessments where impacts are compared to sustainable levels of impacts. This can become an important supplement to the predominant relative environmental assessments, where impacts of different product systems are compared.

### 294

#### Ethical perspectives on planetary boundaries and LCIA

B.P. Weidema, Aalborg University / Danish Centre for Environmental Assessment; M. Brandão, 98 Pahiataua Street

The concept of planetary boundaries has resurfaced the discussion on carrying capacity and target setting for overall environmental impacts. This concept is now widely used in both academic and political decision-making circles, particularly in climate policy after the Copenhagen Accord (2009) made explicit the political aim of "avoiding dangerous climate change" by staying under a 2°C temperature increase. We explore the usefulness of this concept for decisions that carry trade-offs. Some authors see the concept of planetary boundaries as complementary to and compatible with the concept of sustainability. We argue here that the concept of planetary boundaries has a different ethical basis than the concept of sustainability, and that this is parallel to the incompatibility between Distance-To-Target and Damage approaches in life cycle impact assessment (LCIA). The concept of sustainable development implies trade-offs between different needs aiming at optimising production and consumption systems in order to maximise utility within existing constraints, and therefore is firmly grounded in utilitarian ethics. The concept of planetary boundaries, on the other hand, implies the setting of targets not to be exceeded, and thus shifts the focus from relative trade-offs to absolute constraints, and can therefore be seen as an expression of a rule-based ethic. We argue that the choice of weighting methods in LCIA, and the choice between sustainable development and planetary boundaries, is fundamentally an ethical and political choice, and should not be disguised as science. The main relevance of the notion of planetary boundaries is that it raises the issue of tipping points. We argue that it is possible to include the concern for a tipping point in the utilitarian damage approach, without the need to introduce targets, by adding this concern as a separate impact category with its own metric and damage function. We demonstrate this with the global warming metric as an example. We find that the concept of planetary boundaries is incompatible with the concept of sustainable development when applied to policy support, and that the concern for tipping points can be appropriately addressed within the utilitarian ethical framework compatible with the damage approach to impact assessment.

### Midpoint or single score for decision making? (I)

### 295

#### The use of uncertain product footprints in a comparative context

P.J. Henriksson, Leiden University / Institute of Environmental Sciences; J. Guinée, University of Leiden / Institute of Environmental Sciences; R. Heijungs, Leiden University / Faculty of Economics and Business Administration Department

of Econometrics and Operations Research

In response to growing awareness of climate change, requests to establish product carbon footprints (PCFs) have been increasing. PCFs are life cycle assessments (LCA) restricted to just one impact category, global warming. PCF studies generate life cycle inventory (LCI) results, listing the environmental emissions of greenhouse gases (GHGs) from a product's lifecycle, and characterize these by their global warming potentials, producing PCFs that are commonly communicated as point values. In the present research we show that the uncertainties surrounding these point values necessitate more sophisticated ways of communicating PCFs, using different sizes of catfish (*Pangasius spp.*) farms in Vietnam as a case study. As part of an evaluation of European seafood imports from Asia, overall dispersions were determined for a wide range of processes related to Asian aquaculture including different sizes of catfish farming. Once propagated into LCI results using Monte Carlo (MC) simulations, large absolute uncertainties around results made conclusions difficult to reach. As most PCF studies only have a comparative meaning, we then instead used dependent sampling to produce relative results in order to increase the power for identifying environmentally superior products. This approach allowed for dispersions related to more than one of the products under study to be assumed the same, producing correlated samples. These results could, in turn, be tested using paired T-tests that allow for greater statistical power. The present research presents many contending arguments for only comparing LCI and LCA results in relative terms. We therefore argue that PCFs supported by quantitative uncertainty estimates should be used to test hypotheses, rather than to provide point value estimates or plain confidence intervals of products' environmental performance. PCFs were created to meet the need to steer our consumer society towards more sustainable choices. However, carbon footprints constitute a highly politicized field of science, where the decision stakes are high and system uncertainties large. PCFs will therefore always be subject to intense scrutiny. By re-evaluating PCFs as a strictly relative indicator while acknowledging the level of underlying uncertainty, clusters of environmentally superior products or production systems may be identified with a level of confidence.

### 296

#### How to use the available knowledge in LCIA to help understand relative importance and relevance in trade-offs and help making an informed decision: Application to the case of PEF/OEF pilots

S. Humbert, Quantis

The life cycle impact assessment method recommended by the European Commission for the Product Environmental Footprint (PEF) and the Organisation Environmental Footprint (OEF), based on ILCD, is a list of 15 indicators at midpoint. The challenge with this recommended list is when conflicting answers are given depending on the indicator assessed. The objective of this work is to present how to use damage-oriented knowledge to increase analysis capacity, allowing to identify which indicators are dominating "absolute" impacts and therefore should be considered in priority when making a choice between two products. Information based on endpoint and/or damage oriented methods such as IMPACT 2002+, ReCiPe, or IMPACT World+ [www.impactworldplus.org] are used to generate conversion factors to go from midpoints recommended by ILCD to damage indicators. Those factors are used to understand better the trade-offs between products, as for example between rape oil and soya oil, types of packaging, or identify "most relevant impact categories", as for example with organization environmental footprint such as with the retail sector. When using information available in the damage oriented literature applied to the case study of rape oil and soya oil, one sees that impact categories contributing to damage to human health are driven by particulate matter, followed by toxicity, but with ozone depletion, ionizing radiation and photochemical ozone formation being all three significantly smaller. When analyzing impact categories contributing to damage to ecosystem quality, one sees that rape oil has overall slightly more impacts than soya oil. So overall, one sees that rape oil has either equal or more impacts than soya oil (but not less impacts). Therefore, with current information, using damage oriented information, one can better discriminate between two products showing trade-offs in terms of environmental impacts. As for the identification of "most relevant impact categories", this presentation shows that using only normalization at midpoint can lead to biased results, especially when midpoint normalization factors are based on inventories inconsistent with those used for the assessment of the product or the organization under study. This presentation will show the thinking process and how using damage oriented information can help increase application/usefulness of the impact assessment method recommended by the European Commission for PEF and OEF.

### 297

#### A distance-to-target weighting set to assess the progress towards EU 2020 targets

S. Sala, European Commission DG Joint Research Centre / Institute for Environment and Sustainability Sustainability Assessment Unit; V. Castellani, European Commission DG Joint Research Centre / Institute for Environment and Sustainability Sustainability Assessment Unit; L. Benini, JRC Institute for Environment and Sustainability - European Commission / Sustainability Assessment unit

Normalisation and weighting are optional steps according to ISO14040. However,

in the context of LCA in support to policy they can help: i) to identify the most relevant impact categories in a given region or for a given product, i.e. to define Product Category Rules (PCRs) for product labelling (as in the case of Product Environmental Footprint – PEF – of products (EC, 2013); ii) to address eco-innovation policies and strategies towards the most effective solutions for decoupling. Distance-to-target (DTT) methods are weighting methods aimed at assessing the distance of an existing situation from a desired state (the target). Weighting factors in distance-to-targets methods could be based on calculation which are performed on normalisation factors (NF's) developed for Life Cycle Assessment (LCA). The NF's express the total impact of a reference region for a certain impact category (e.g. climate change, eutrophication, etc.) in a reference year, whereas weighting reflects a process of giving different relative importance to impacts based upon criteria. The weighting factor is defined for each environmental impact category as the ratio between the actual impact and the target impact. The targets impacts can be the desirable level of impact foreseen by policy targets or physical targets or thresholds not to be trespassed, as in the case of planetary boundaries. In the present study, the target value for each impact category is derived from EU policy targets for 2020. Therefore, normalization reference values are the NF's for the current environmental scenario (reflecting the status quo in 2010) and targets values are derived from the application of policy targets for 2020. The methodology implemented for calculating NFs2020 and related weighting factors (WFs) applies a distance to target method based on binding and non-binding EU policy targets for 2020. The methodological steps are: 1. Identification of binding and non-binding EU targets for 2020; 2. Development of the inventory in which targets are implemented; 3. Calculation of two sets of weighting factors, based on binding and non-binding targets, respectively. The methodology allowed to derive DTT weighting factors at the EU scale based on policy targets. The resulting sets present strength and limitation that will be discussed especially in light of their use for policy support

298

#### **Single score methods and midpoint indicators: a dream team for an effective environmental policy**

S. Buessler, R. Frischknecht, treeze Ltd.; C. Nathani, Ruetter Partner Human societies consume more and more non-renewable resources, and several renewable resources are being depleted beyond their capacity of regeneration. That is the reason why measures are required to lower the environmental impacts of human society. In order to do so national authorities need to know the actual situation regarding emissions of pollutants and extraction of resources. Comprehensive national environmental statistics are one important prerequisite. Besides, it is also important to know the levels and trends of the environmental impacts related to the traded commodities and services. The environmental impacts of products and services consumed in a country need to be quantified along their entire life cycle disregarding national borders. Finally, national action plans targeted to improve the environmental impacts of a nation's consumption require prioritisation. Single score life cycle impact assessment methods in combination with mid-point indicators are one mean to support this process and help identifying those areas where a reduction in the overall environmental impacts are most promising and effective. In this presentation the development of the environmental impacts caused by Swiss final consumption from 1996 to 2011 is described with a focus on the roles of single score and midpoint indicators in view of national environmental policies. With the help of single score indicators the main environmental impacts can be identified. Single score indicators help to identify those imported groups of goods with significant shares on the net traded environmental impacts. Using the single score results, the question how much the environmental impact exceeds the naturally sustainable level may be answered in two different ways. Both possibilities are discussed in the presentation. Midpoint indicator results are used to identify the reduction requirement per environmental topic. While Swiss consumption based greenhouse gas emissions should be reduced significantly, Swiss consumption based impacts on water quality require less action. Hence, single score indicators are helpful in showing the big picture and identifying environmental hotspots of the consumption based environmental impact of a nation whereas midpoint indicators help to identify specific reduction targets and develop measures to reach them.

299

#### **Analysis and comparison of monetarization methods with application to two paint formulations**

J. Lindberg, IVL Swedish Environmental Research Institute; K.A. Halldén, Akzo Nobel / Sustainability; M. Lindblad, H. Tekie, T.V. Rydberg, IVL Swedish Environmental Research Institute Translating environmental impact indicators into economic cost burden for present and future societies, i.e. monetarization, is one available approach for achieving single score results in Life Cycle Assessment (LCA). A study was conducted, with the aim to explore different monetarization methods and apply them to two decorative paints, a former paint formulation and a new paint formulation, in order to investigate the impacts on single scores level. To present the result on single score level has its pros and cons in relation to midpoint level, where the single score gives clear result for example when comparing products, but on the other hand is based on subjective value judgment. The three monetary weighting methods used in the study were Environmental priority strategies - EPS, Stepwise and Ecovalue.

There are many aspects of a weighting method and different methods could be suitable in different application areas and decision situations. The three methods were selected from different criteria for example environmental representativeness, valuation attached to midpoint and endpoint level, principles of the weighting methods (what are the values based on, whose values are used and how the values are derived). All methods covered a broad range of environmental impacts or damages, both midpoint and endpoint methods were represented and the methods are based on different principles. The aim of this is to assail the result from different angles and to overcome data gaps. The overall result showed differences with a factor of three between the method with lowest (Ecovalue) and highest (EPS) environmental costs for the specific paints in the study. The largest contributions to the environmental costs were given by the climate change category or related damages, but also particulate matter formation or related impacts gave a high contribution for the three methods. In the course of the study, it was observed that the methods are typically based on marginal cost estimates. The implications of this choice in relation to attributional or consequential modelling in LCA are discussed, as it can be argued that an average cost model would be more consistent with the conventional attributional LCA modelling practice.

300

#### **The Method of Ecological Scarcity: Adaptation to German Framework Conditions as Tool for Environmental Management**

L. Schebek, Technische Universität Darmstadt / Material Flow Management and Resource Economy; S. Ahbe, Syron; N. Jansky, TU Darmstadt / Institute IWAR Material Flow Management and Resource Economy; S. Weihofen, S. Wellge, Volkswagen Group Research Environment The Ecological Scarcity Method (ESM), also called Ecopoint Method, has been developed in Switzerland in the late 1980ies as one of the earliest approaches for assessment of environmental impacts of substances or material flows [1]. Among its wide-spread use, the EMS method has been also applied in the framework of company environmental management: in 2001, the Volkswagen AG (VW) developed an assessment procedure for environmental aspects in the framework of EMAS (European Management and Auditing Scheme), which is based on the ESM approach [2] and since then has been used for all EMAS audits at VW's company production sites across Europe. However, factors provided for ESM from [1] are based exclusively on Swiss framework conditions. This has been recognized as a point of criticism for use in site-specific assessments outside of Switzerland where national targets as well as environmental impacts may differ considerably. As a first step to overcome this problem, in 2012 VW launched a project to adapt the ESM method to German framework conditions. The scientific work of this project covered the adaption of the list of eco-factors itself as well as the definition of figures for Critical and Current Flows for Germany. A set of twenty eco-factors concerning the most relevant environmental impacts was developed [3], which will be presented and discussed in detail. These eco-factors reflect the German framework conditions in the sense that they incorporate German legal targets (e.g. as to emission levels) or policy targets (e.g. as to GHG reduction), as well as most current data on respective substance or material flows. This approach is in line with the general principle of distance-to-target underlying the ESM method. As to the ESM method in general, it is sometimes criticized that targets are not exclusively based on natural science but include political settings. However, it should be recognized that often natural science cannot yet provide clear limits for environmental impacts, and that political targets are formulated by democratic procedures, reflecting a consensus process of stakeholders. Therefore it should be the general interest of society to implement political targets for specific target setting of stakeholder groups. In this sense, eco-factors are clearly most suitable specifically for use in environmental management. Here, also the continuous agenda setting within the Audit Schedule may be supported by regular up-dating of eco-factors.

#### **Assessment of risks posed by systemic insecticides to hymenopteran pollinators: from lab via (semi-)field to landscape scale (II)**

301

#### **Dust drift during sowing of pesticides treated seeds - imission in adjacent areas and effects on honey bees**

U. Heimbach, JKI / A; M. Stähler, JKI / Institute for Ecological Chemistry Plant Analysis and Stored Product Protection; D. Schenke, Institute for Ecological Chemistry, Plant Analysis and Stored Product Protection; J. Pistorius, Julius Kühn-Institut Seeds of many crops are treated with insecticides to protect young seedlings against pests. During sowing of clothianidin maize bee poisoning of about 12,000 hives was observed in Germany in 2008. Relevant amounts of clothianidin drifted into adjacent flowering crops in the form of contaminated dust. The release of dust into adjacent areas is generally influenced by the amount of dust set free during drilling (Heubach value), percent of a.s. in dust, dust particle size, amount of seeds used per ha, sowing width and type of sowing machinery, wind, and soil conditions. Field experiments were carried out using different batches of seeds. The abrasion potential of seed batches was analysed using the Heubach Dustmeter. Residues in

Petri dishes on bare soil only fell slowly with increasing distance (fig 1). Generally higher Heubach values or higher amounts of a.s. in dust resulted in higher drift values. Residues of a.s. (in g/ha) in adjacent crops were up to about 5 times higher compared to values of Petri dishes (in g/ha) in open areas at 1 m distance in several experiments. This points out a filtering capacity of adjacent plants. Residues in flowering parts of the adjacent crops were high and reached critical levels in some experiments depending on the abrasion of seeds sown. Bee exposure experiments were conducted parallel to drift experiments and showed clear bee toxicity in some of the experiments. Bee exposure experiments were conducted parallel to drift experiments and showed clear bee effects in some of the experiments. E.g. in the autumn 2013 experiment for few days some increased bee mortality was observed in tents with honeybees placed directly adjacent to the drilled area after sowing. No such effect was visible during open field exposure of honey bees in this experiment. No effects on bees were observed in the 2014 experiment, neither in tent nor in open field exposure. Risk mitigation for pesticide treated seeds seems possible with an improvement of the seed coating quality regarding content of loose dust, maximum amount of active substances in dust and with improvements of sowing techniques.

### 302

#### Imidacloprid and immunity: a bumble bee perspective

E.J. Collison, Food and Environment Research Agency / Biosciences College of Life and Environmental Sciences; H. Hird, The Food and Environment Research Agency; C.R. Tyler, Biosciences College of Life and Environmental Sciences; J. Cresswell, Exeter University

Multiple stressors are likely contributing to declines in bee health, including pesticide application and the spread of pathogens and parasites. Recent recommendations for the risk assessment of plant protection products on bees have included the need for a better understanding of pesticide-disease interactions and the development of biomarkers to evaluate sublethal effects of pesticide exposure, such as immune system changes. Studies have begun to investigate the biological mechanisms underlying pesticide-disease interactions in honey bees, and there is some evidence that exposure to neonicotinoid pesticides impairs the honey bee immune response. However, there has been no investigation of neonicotinoid effects on the bumble bee immune response despite recognition that the sensitivity to neonicotinoids, and endpoints appropriate for risk assessment, could differ between bee species. Here a laboratory study was set up to investigate the effects of a chronic oral neonicotinoid exposure on the immune response of the bumble bee (*Bombus terrestris audax*). We tested whether imidacloprid exposure impaired the ability of workers to respond to an artificial immune challenge with *E.coli* lipopolysaccharides (LPS), measuring two components of the insect immune response- phenoloxidase enzyme activity (associated with a melanisation response), and antimicrobial protein (AMP) activity. Neither immune challenge nor imidacloprid exposure was found to affect phenoloxidase enzyme activity in the bumble bee immune response. Injection with LPS lead to a significant induction of antimicrobial protein activity compared to unchallenged (naïve) controls, likely due to a combination of wounding during injection and response to the bacterial LPS molecules. The induction of AMP activity in response to LPS injection was found to be impaired in bees exposed to the highest concentration of imidacloprid (125 µg/L<sup>-1</sup>; ≈ 102 ppb), but there were no significant effects on AMP activity at more field relevant imidacloprid exposures. We conclude that the phenoloxidase response to immune challenge remains difficult to interpret and may be of little value to pesticide risk assessment. Our data also question the value of AMP immune endpoints for use in pesticide risk assessment, although we recognise that further work is needed to establish the extent to which pesticide exposures may impair the bumble bee immune response to natural pathogenic infections.

### 303

#### Modelling honeybee foraging in complex landscapes and consequences for exposure to pesticides in the bee hive

h. haveco, Environmental Risk Assessment Team; A. Focks, Alterra Wageningen University and Research Centre / Ecotoxicology Environmental Risk Assessment Team; I. Roessink, Alterra; D. Belgers, Alterra Wageningen UR; J. Van der Steen, Wageningen UR; J. Boesten, Alterra / ERA team

Within the recent EFSA guidance document on the risk assessment of plant protection products on bees [1], the risk assessment for the consumption of nectar and pollen in the hive is based on the conservative approach that bees forage exclusively on one type of plant. The guidance gives options to replace this conservative with a more realistic approach considering foraging on all attractive plants in the foraging area at the landscape level and presents a simple model approach that assumes that the fraction of honey bees foraging in each field within a certain maximum foraging radius, is proportional to the product of attractiveness (e.g. defined by nectar yield) and area of each field. We implemented a spatially explicit version of the parsimonious EFSA model. In addition, we developed a mechanistic, energetics-based foraging model as an alternative. By quantifying foraging costs and yield in terms of energy [2], we can account for the impact of field distance and size, the occurrence of resource depletion and the characteristics of the resource type (crops and wild flowers) like seasonal and diurnal patterns in availability. Both spatially-explicit models used detailed GIS data for crop coverage and distribution of potentially nectar-providing off-crop habitats in the Netherlands. We tested the models with an artificial test landscape and calculated dilution factors for all possible bee hive positions in the landscape. The set of

resulting dilution factors was analysed and statistical descriptors such as median values or percentiles were extracted. [1] EFSA (2013). Guidance on the risk assessment of plant protection products on bees (*Apis mellifera*, *Bombus* spp. and solitary bees). EFSA Journal **11**(7): 3295. [2] Baveco, J. M., et al. (2011). ### 304

#### The prediction of the partition behaviour of chemicals in the honey bee colony based on the architecture and chemical composition of the hive compartments

K. Hørig, RWTH Aachen University / Institute for Environmental Research; C.D. Maus; H. Ratte, ToxRat Solutions GmbH / Institute for Environmental Research; M. Ross-Nickoll, RWTH Aachen / Institute for Environmental Research BioV; T.G. Preuss, Bayer CropScience / Environmental Modelling

Pollination has to be considered as an important factor in food economy and the honey bee *Apis mellifera* is the most important commercial pollinator. Over the last few years, potential effects of insecticides on bee colonies have been discussed. There is largely consensus that the risk assessment for bees will benefit from a deeper understanding of mechanisms of bee exposure to pesticides and to understand the effects of toxicants in the bee hive it is important to fully understand their fate within bee colonies. Spatial distribution of plant protection products is calculated between compartments in the honey bee colony – a needful extension to an approach that investigates the distribution that is carried by worker bees and their movements in order to describe the substance distribution in the honey bee colony in its full extend. The partition will be described considering the specific “architecture” of the honey bee comb cells, the chemical constituents of the different matrices and the partition coefficient of the substances of which the distribution behaviour is examined. The methods of investigating the partition behaviour of substances between the different matrices in the honey bee colony are compared to literature data. The calculated partition behaviour is in agreement with data from literature. The model generates results that correspond with values obtained from examined hives. As a submodel of a general model that describes the toxicokinetics of substances in the honey bee colony, it will perform the task of calculating the substance transfer between storages as well as brood and wax.

### 305

#### Pollinator profile of the novel Cyantraniliprole insecticides

A. Dinter, DuPont de Nemours (Deutschland) GmbH / Crop Protection; A. Samel, DuPont Crop Protection / Ecotoxicology

Cyantraniliprole (DPX-HGW86, DuPont<sup>TM</sup> Cyazypyr<sup>®</sup>) is an anthranilic diamide insecticide (IRAC Group 28) and the first to control a cross-spectrum of chewing and sucking pests. Cyantraniliprole is a systemic insecticide and products containing cyantraniliprole are optimized for foliar or soil applications and are effective on a wide range of crops (i.e. vegetables and top fruits). Application rates vary for different pests and crops between 12.5 to 150 g cyantraniliprole/ha with up to 2 applications per crop. The acute oral and contact honeybee (*Apis mellifera*) toxicity of the active substance, cyantraniliprole, its formulated products, Cyantraniliprole 100 g/L OD (DuPont<sup>TM</sup> Benevia<sup>®</sup>), Cyantraniliprole 100°g/L SE (DuPont<sup>TM</sup> Exirel<sup>®</sup>) and Cyantraniliprole 200 g/L SC (DuPont<sup>TM</sup> Verimark<sup>®</sup>), and several plant metabolites was characterized in laboratory tests. Cyantraniliprole foliage residues resulting from sprays up to the maximum intended use rate of 150 g cyantraniliprole/ha and aged for 33 hours were found to pose low risk for honeybees. The potential oral exposure of honeybees via pollen and/or nectar to cyantraniliprole and its metabolites was investigated in laboratory translocation studies and in field residue studies. Also residues in bee matrices were determined in honeybee field trials e.g. in nectar and pollen. In honeybee tunnel tests with e.g. *Phacelia*, apple, nectarine and melon the potential risk for honeybees under worst-case semi-field conditions was assessed. A bee brood tunnel test investigated specifically potential effects on honeybee larval stages. In large scale honey bee field trials in rape the potential impact on honeybee colonies was investigated. A honeybee melon field trial investigated the potential effects on honeybees for a relevant crop for the intended uses of cyantraniliprole. The compatibility of the use of cyantraniliprole products with pollinating bumblebees (*Bombus terrestris*) was studied and proven in a greenhouse study in Spain. Overall, it was found that the intended uses of DuPont cyantraniliprole products according to good Agricultural Practice pose no unacceptable risks for pollinators.

### 306

#### A causal analysis of the role of neonicotinoid insecticides in the reported losses of bee colonies (*Apis mellifera*)

R. Schmuck, Bayer CropScience AG / Environmental Safety

Reported declines in overwinter survival of bee colonies (*Apis mellifera*) in Western Europe, and the onset of colony collapse disorder in 2006 in North America encouraged many researchers to investigate the causative factors behind the bee health problem. Throughout many study reports on this subject, there is a peculiar hierarchy of reasoning: first that the increased numbers of bee losses are due to multiple causes, including stress caused by unspecified pesticides, then that pesticides must be given priority in the investigation of the effects, and then that neonicotinoids are the pesticides of concern. There have been incidents of acute

toxicity that appear to be linked to exposure of bees to dust from neonicotinoid seed treatments, but these are unrelated to the kind of chronic toxicity and effects from sublethal exposure that have been postulated. The author performed a causal analysis of reported declines in bee colonies with a special emphasis on the role of neonicotinoid insecticides.

## Improving approaches for difficult non-standard risk assessment of chemicals

307

### Risk assessment methods for naturally-occurring substances

P.R. Fisk, Saxon House; D. Akinosho, Peter Fisk Associates Limited; L. Wilmot, Peter Fisk Associates / John Roberts Business Park; O. Dosunmu, Peter Fisk Associates Limited

Naturally-occurring substances can be monoconstituent (e.g. metal ions or organic molecules) or multi-constituent/UVCB (e.g. plant extracts). It can be misleading to assume that all naturally-occurring substances are benign, or that organisms are unaffected by them. The standard methods for risk assessment specified REACH have been developed mainly for anthropogenic substances, and could yield misleading results when applied to naturally-occurring substances without serious consideration of the assumptions. Risk assessments of organic naturally-occurring substances present their own scientific challenges when compared to anthropogenic substances. The substances are inevitably already present in the environment and the potential risks in increasing exposure to these substances over background levels need to be considered. This paper covers substances that: occur naturally in the environment, are essential nutrients occur endogenously i.e. are present in organisms including humans from metabolic processes. It addresses the following:

- The relationship between the natural origin of the substance and risk assessment strategy.
- How an assessment is performed when the amount released into the environment is below the background level already present.
- How to deal with PNECs at concentrations which are below the background level in the environment.
- For man via the environment, how to deal with the issue of mammalian DNEL at concentrations which are below the safe level for substances that are essential nutrients or which are natural metabolites in the body. The following steps have been identified, and will be exemplified: 1: Identify and characterise the naturally-occurring substance 2: Identify the natural origin or source 3: Obtain or determine the background concentration of the substance occurring naturally in the environment and in humans 4: Identify the uses of the substance that will likely lead to an increase in exposure above background concentration levels in the environment and in humans 5: Assess exposure (including background levels) 6: Obtain hazard property data 7: Interpret the hazard data relative to the background concentration levels 8: Review and finalise the assessment strategy 9: Characterise risk

In respect of properties, biodegradability presents particular problems because standard studies are not always appropriate and other information from known metabolic pathways should be included.

308

### An Integrated Fact Sheet for the classification of complex inorganic materials for environmental hazard

D. Heijerick, ARCHE; V. VEROUGSTRAETE, Eurometaux / EHS; B. Davies, ICMM; H. Waeterschoot, Eurometaux; M. van Gheluwe, ARCHE

The general strategy for classifying chemical substances, compounds and mixtures for the aquatic environment is hazard-based, and takes into account the intrinsic properties (short and long term aquatic toxicity, solubility, degradation, and bioaccumulation) of the substance or those of its components (OECD 2001a). The United Nations' Globally Harmonized System (UN-GHS) and the European Union's Classification, Labelling and Packaging are two important pieces of legislations setting out procedures on how to derive correct classifications. For metals and metal compounds the evaluation of both short term and long term aquatic hazard potentials is based on appropriate standard ecotoxicity data as determined with the soluble metal salt (acute and chronic values) and comparison with the classification cut-off values. A number of problems are, however, encountered when trying to use the methodology developed for soluble substances, to classify insoluble metals, sparingly soluble metal compounds (SSMC) and complex metallic materials such as alloys and ores & ore concentrates (hereafter called O&C). Guidance on how to deal with the specific properties of such materials when deriving a relevant environmental classification has been provided in different notes, recently brought together in an Integrated Fact Sheet on the classification of complex inorganic materials. The overall classification methodology, as well as specific guidance for various types of complex inorganic materials (with some emphasis on alloys), is provided in this presentation. The overall classification strategy for complex inorganic materials is a tiered approach, with each Tier requiring a higher level of detail on the composition, and on the physico-chemical and bioavailability properties of the material. In addition, as conducting tests and analyses on every complex inorganic material is technically not feasible, it is recommended to group different materials together and to develop a rationale for grouping materials together using information that is collected during the characterisation phase of each material. The developed classification strategy has been put in practice on several alloys and O&Cs, and this exercise demonstrated that worst-case classification – based on the Tier 1 approach – can be

refined to a more realistic classification when higher tiers can be applied.

### The Hydrocarbon Block Method for Environmental Risk Assessment of Petroleum Products

M. Leon Paumen, ExxonMobil Biomedical Sciences / ExxonMobil Biomedical Sciences TES Division; M. Comber; C.V. Eadsforth, Shell International; K. den Haan, CONCAWE / Petroleum Products Safety; S. Linington, BP Castrol Technology Centre; A.D. Redman, Exxon Mobil Biomedical Sciences; T. Parkerton, ExxonMobil Biomedical Sciences Inc.

CONCAWE has developed an approach for assessing the risks to man and the environment complying with the requirements of REACH. The approach adopted for assessing the environmental fate and effects of these categories is based on the Hydrocarbon Block Method (HBM) as described in the Technical Guidance supporting REACH. Within the guidance it is clear that it is necessary to develop a specific testing strategy to ensure that the composition of the sample to be tested in the laboratory reflects fully the composition of the likely human or environmental exposure. Given the complex nature of petroleum products these are likely to fractionate once released into the environment, and the HBM approach addresses this by assuming that the risk assessment can address the components of the UVCB as though these components were single substances. The strategy has three main strands: 1. Characterising the substance and identifying the HBs and possible constituents 2. Compile relevant physical-chemical, fate and effect properties for HB constituents 3. Estimate environmental emissions and the environmental exposures of the constituents Based on these data and the assumption that there is common mode of action, narcosis, the risks of the components are summed thus giving the overall risk of the product, under assessment. Obviously, the CONCAWE approach described above, only addresses the environmental risks for the whole product that arise from normal use (i.e. spillages are excluded). As such the talk will also address how the behaviour of the whole product differs from that of constituents and thus the concerns that arise when addressing the whole product with respect to the potential for erroneous estimation of the environmental risks. The key questions that come from this approach that will be touched on during this presentation are: - How is uncertainty in the composition of a product addressed both in terms of absolute differences and on the impact of varying HBs? - Where there are many thousands of possible constituents, what uncertainty is introduced by the simplification of HBs to only a few structures? - Can uncertainties in emissions be quantified and if so how do they get addressed?

### Non-standard risk assessment - exploring the boundaries

K. Monsieus, Apeiron Team n.v.; T. Vandenbrouck, Apeiron-Team; H. Moerman, E. Van Asbroeck, Apeiron-team NV

The fundamental principles of risk assessment of chemicals are well established, and in the framework of REACH, detailed guidance is made available by the European Chemicals Agency (ECHA) on how to conduct a 'standard' chemical safety assessment. Nevertheless, for the chemical safety assessment of more complex cases, the standard principles often are not directly or not fully applicable, and expert judgement is required to come to a conclusion regarding the thresholds of safe use (DNELs, PNECs), the PBT status, or for the determination of relevant exposure levels. Specific physicochemical properties of the substance, such as a high volatility, a low water solubility, a high tendency to adsorb to solid matter, et cetera can easily lead to non-standard risk assessments as these properties require non-standard test designs and possibly even non-standard ways interpreting the data, which is not always foreseen in the available guidance/legislation. The risk assessment is even prone to an additional level of complexity when it regards complex substances containing a high number of (similar or unsimilar) chemical constituents. In those cases, the assessment can be hampered by the difference in physicochemical, toxicological and/or ecotoxicological properties of each constituent. Consequently, different constituents could exert different toxicokinetic behaviour (e.g. adsorption, distribution, accumulation) and lead to different metabolites. Likewise, the environmental fate of the constituents may be different, e.g. leading to differences in biodegradability or a different distribution between the environmental compartments. In this presentation, we will discuss two (anonymized) cases in which the standard risk assessment principles could not be applied. The first case deals with a substance of complex composition. The substance contains 30+ constituents with a variable but low water solubility. The second case deals with a PBT assessment for an organic substance that has a high tendency for adsorption. The challenges faced were the following: (i) How to design a reliable test?, (ii) Will the adaptations to the standard approaches be accepted in a regulatory context?, (iii) Time: how to meet the regulatory deadlines while time for development of a non-standard test is not foreseen in the regulation(s), (iv) Proportionality. The described case studies will address the experienced interplay between the regulatory, industrial and academic points of view.

311

### The "Assessment Entity" - an approach to support the transparency of Chemical Safety Assessments under REACH

h. magaud; A. Ahrens, ECHA; C. Tissier, ECHA-European Chemicals Agency / Risk Management; J. Vasquez Rodriguez, ECHA European Chemicals Agency

Registrants of substances under the REACH regulation are obliged to carry out a safety assessment for their substance if the manufactured or imported amount exceeds 10 tons per year. If the substance meets the criteria to be classified as hazardous the safety assessment must include exposure assessments for all uses of the substance and a corresponding risk characterisation. The assessment is expected to cover the whole life cycle of the substance. The exposure assessment shall take into account transformation and/or degradation products of the substance that may occur during use or after release into the environment. A substance registered under REACH may consist of various constituents with a narrow or wide range of properties, it may vary in its composition or forms, and the corresponding hazard profile and the use pattern of the substance may be different for different forms or compositions. Consequently a safety assessor under REACH may be confronted with relatively complex assessment cases and transparent documentation in the registration dossier may be a challenge. In order to improve transparency of assessments in the future ECHA has developed the so called "assessment entity" approach aiming to support a transparent organisation of assessment data for substances with a more complex chemistry. The "assessment entity" is a wrapper [container] for a set of substance property data (across endpoints) used for assessment purpose. It enables the identification and tracing of one consistent dataset per exposure assessment when two or more compositions/constituents are to be taken into account in the assessment separately from each other. This approach will be incorporated in the new generation of IUCLID and Chesar, ECHA's tools for registrants to report data and to assess hazards, exposure and risks. The new functionalities will support the definition of assessment entities and will enable the setting of links between various data sets that form a safety assessment, e.g. the compositions/forms of a substance or groups of constituents, the corresponding substance property and hazard profiles, the relevant uses, the conditions of use and the corresponding exposure estimates.

312

### The Application of Reactivity Driven Profiling to Identify Chemicals of Higher Concern

M.A. Bonnell, Environment Canada / Ecological Assessment Division; O. Mekenyan, Prof Dr Assen Zlatarov University / Laboratory of Mathematical Chemist

The ultimate goal of chemical evaluation is to answer the hypothesis question of whether a chemical has the potential to cause adverse effects in target organisms. This question has been answered both in the near field (local environment) as well as the far field (remotely or globally distributed). The prioritization and assessment of organic chemicals has often been approached using hazard properties (i.e., PBT, vPvB), which because of the history and domain of the criteria for these properties, may not adequately address some reactive and potentially quite potent chemistries that are highly soluble in water (e.g., pharmaceuticals). It can also be argued that the criteria for these properties better capture chemicals that can exist in the far field (e.g., air half-life >2 days, water half-life >182 days) and may not address chemicals in the near field that are "continuously present" and yet potent beyond baseline narcosis. As a consequence there is a very real danger of making false negative conclusions and committing Type II error during decision-making for certain chemicals. Here we present an approach that compliments PBT analysis with *in silico* mechanistic profiling to better address reactivity, ADME and the tautomeric properties of a chemical. The anionic dye/drug additive/insecticide Phloxine B, will be used to demonstrate this approach particularly because it would not be captured as a PBT or vPvB chemical in the situation of no empirical data. Two scenarios will be presented to reveal possible outcomes of risk conclusions: (1) PBT profiling approach assuming no data, and (2) enhanced PBT profiling to include reactivity and ADME profiling also assuming no data. These scenarios are then compared with available empirical data including bioaccumulation and ecotoxicity testing in a soil organism. Recommendations are made as to how enhanced hazard property profiling can be achieved by combining PBT and mechanistic approaches to avoid Type II for these "difficult to assess" substances.

## Soil and water pollutants' assessment, monitoring and remediation (II)

313

### Effects-directed approach to assess changes in PAH composition and toxicity following soil bioremediation

S. Simonich, Oregon State University / Depts of Chemistry and Environmental Molecular Toxicology; L. Chibwe, Oregon State University / EMT  
The bioremediation of soils contaminated with polycyclic aromatic hydrocarbons (PAHs) is a concern due to the potential formation of more toxic oxygenated byproducts. PAHs are persistent in the environment, resistant to biodegradation, and some are known to have carcinogenic and mutagenic properties. Their oxygenated derivatives are more likely to be mobile in the environment, and could pose greater health risks. This study utilizes an effects-directed approach, combining toxicity analysis using the novel DT40 chicken bioassay, and gas chromatography mass spectrometry (GC/MS) for chemical analysis. The purpose of the study is to isolate and identify compounds in soil, which could potentially be the cause for increased toxicity in soil post bioremediation. We developed an extraction method using pressurized liquid extraction (PLE), and fractionated the

contaminants in the soil using silica solid phase extraction (SPE), by varying solvent elution polarity. The DT40 bioassay was then used to assess the toxicity of the different fractions. We observed an increase in the overall toxicity of the soil, and an increase in genotoxicity and mutagenicity in certain fractions post bioremediation.

314

### Bacterial mobilization by chemotaxis as an innovative promoter for bioremediation techniques

C. Jimenez Sanchez, Inst de Recursos Naturales y Agrobiol. de Sevilla / Agroquímica y Conservación de Suelos; J. Ortega-Calvo, Instituto de Recursos Naturales y Agrobiología / Agroquímica y Conservación del Suelo  
Bioremediation techniques can be limited by a low bioavailability which represents the accessibility of the chemicals for biotransformation and toxicity to microorganisms. Even more, bacterial mobilization in soils may be restricted by several factors, including increased path lengths (tortuosity), bacterial adhesion to surfaces, and geometrical restrictions due to pores of small diameter and dead ends. We propose bacterial tactic response as a mechanism that could change the swimming behavior and hence improve bacterial mobilization in saturated porous media, thus promoting an enhanced biodegradation of pollutants. We characterized the tactic response of naphthalene-degrading *Pseudomonas putida* G7 to different dissolved organic matter (DOM) sources by capillary assays and by computer-assisted motion analysis. Sunflower root exudates and humic acids (HA) were used as representatives of fresh and weathered DOM at high concentrations (~130 mg L<sup>-1</sup>) and at low DOM concentrations (~16 mg L<sup>-1</sup>). To test the effect of tactic motility in the bacterial mobilization in soils, we assessed the influence of DOM on bacterial strain deposition in porous media (sand) in well-controlled column systems. We suggest that chemotactic sensing combined with changed swimming modes could be the reason for the enhanced bacterial transport observed with sunflower root exudates. We analyzed some motility parameters like speed or rate of changes of direction to determine the effect of exudates on swimming trajectories. Humic acids also promoted bacterial transport, but this effect was caused by other mechanism different to chemotaxis, and possibly involved physical interactions between the cell surface, the porous material and the DOM.

315

### Impact of organic additives on the immobilization of heavy metals in the phytoremediation process of degraded soils

A.E. Placek, A. Grobelak, Czestochowa University of Technology / Institute of Environmental Engineering; D.P. Włoka, Czestochowa University of Technology / The Faculty of Environmental Engineering and Biotechnology; A.R. Almas, Norwegian University of Life Science

The presence of heavy metals in the natural environment, especially in areas used for agriculture, is an important issue for environmental concerns. Trace elements by plant organisms can be included in the food chain and biological circulation. A characteristic feature of heavy metals is also capability to remain in the environment for long period of time, as well as resistance to chemical and biological degradation. Phytoremediation process involves a variety of techniques which involves the plants for the treatment of soil from organic and inorganic contaminants. An additional advantage of phytoremediation of soils is the possibility of using waste and by-products as soil additives to support this process and at the same time to affect the recycling and disposal of a significant amount of waste substances. Soil organic additives are a source of organic matter and biogenic elements which affect a significant improvement in the quality of the soil environment. Moreover, they have the sorption ability related to the immobilization of contaminants in soil. The aim of the research was to determine how the application of organic additives into the soil surface improves the phytoremediation process (conducted with two plant species) of soils contaminated with heavy metals. The pot experiment was 1 year carried out under controlled conditions of phytotron chamber. Soil material used in the study was collected from two sites (Poland): the area in the zone of zinc smelter influence located in (Silesia region) and also from post-mining land lignite mine dump in Belchatow. In this experiment the following plant species were used: forest species (*Pinus sylvestris* L.) and energy crops (*Miscanthus giganteus*). The amendments used for this study were different types of organic amendments: sewage sludge, composts, coal mules, lacustrine chalk to determine the degree of immobilization of pollutants in the soil. The mobility of heavy metals in the soil can be decreased by the application of organic additives such as: lacustrine chalk and compost from municipal waste compost (compost 1). Selected energy crops, because of its excellent adaptability to change habitat conditions, the possibility of gradual reclamation of degraded land and the ability to prevent the migration of heavy metals into the soil and groundwater that also enter the food chain, can be used in the remediation of soil and of soilless devastated areas, as pioneering plants.

316

### Restoration of Contaminant-Impaired Ecosystems: Prevention or Cure?

A.M. Farag, U.S. Geological Survey; R.N. Hull, Intrinsik Environmental Sciences Inc.; W.H. Clements, Colorado State University / Fish Wildlife and Conservation Biology; S. Glomb, IOSDOI / Office of Restoration and Damage Assessment; D. Larson; R.G. Stahl, E.I. DuPont de Nemours and Company / Corp Remediation; J.L. Stauber, CSIRO; M.J. Hooper, USGS Columbia Environmental Research

Center / Columbia Environmental Research Center; L. Kapustka, LK Consultancy; S.N. Luoma, University of California, Davis / John Muir Institute of the Environment; J.R. Rohr, University of South Florida / Department of Integrative Biology; A. Wagner, Chevron

Multiple stressors from human activities are increasingly altering the composition and integrity of our aquatic and terrestrial ecosystems. Land use change, mining impacts, increasing urbanization and climate change are already having a major impact on habitats, ecological processes and communities. The restoration of contaminated ecosystems is even more important as open spaces and aquatic resources become more limited throughout the world. The processes of preventing contamination during restoration activities and restoring contaminated ecosystems have unique issues that must be addressed including selection of ecosystem restoration goals (to what do we restore?), restoration design (how do we restore?), restoration effectiveness (have we been successful?) and anticipating pitfalls (e.g. potential for attractive nuisance). This paper will discuss highlights of a recent joint SETAC/SER-sponsored technical workshop on Restoration of Impaired Ecosystems. Experts in the fields of aquatic and terrestrial ecotoxicology, restoration, and related fields from both SETAC and the Society for Ecological Restoration (SER) worked together to address issues and discuss case studies to illustrate key approaches and research needs in ecosystem restoration. The overall objective of the workshop was to define the best scientific practices available for preventive restoration to limit potential contamination and for restoration of aquatic and terrestrial ecosystems where toxicants have been released. This multi-disciplinary approach and key outcomes from the workshop will be discussed.

317

#### **The induced biodegradation of polycyclic aromatic hydrocarbons (PAHs) in cultivation of *Phalaris arundinacea***

D.P. Włóka, Czestochowa University of Technology / The Faculty of Environmental Engineering and Biotechnology; A.E. Placek, M. Kacprzak, Czestochowa University of Technology / Institute of Environmental Engineering Polycyclic aromatic hydrocarbons (PAHs) belong to the group of most commonly present in environment organic contaminants. PAHs are build from at least two aromatic rings and don't have any additional substituent's. They are hardly soluble in water, however in presences of soil soluble organic fraction, they can easily migrate to the deeper layers of soil profile. Due to the proven cancerogenic activity of some representatives of PAHs, the occurrences of this substances in agriculture soil is considered as potential risk to human health. Taking in around the above maintained facts it can be stated that studies aimed to develop or evaluate new environmental friendly methods for PAHs remediation are very important. The aim of this study was to investigate the effectiveness of PAHs biodegradation in growing of *Phalaris arundinacea*, fertilized with sewage sludge and mineral sorbents. The study was conducted under the controlled conditions, by using the phytotron chamber. An experiment includes three steps. The first step rely on performing complete characterization of used materials. Second step included the preparation of analytical stand and 6-month incubation. During the incubation, in week 24th the soil and leachate samples from each reactor were collected. Next, the soil samples were subjected to PAHs content analysis and the leachate samples were subjected to total carbon (TC) and total organic carbon (TOC) content analysis. Step third includes the secondary measurements of soil physical and chemical properties. Prepared experiment was consisted of 8 aerobic bioreactors. Each bioreactor was filled with following materials: 1-Soil; 2-Soil; 3-Soil+Sewage Sludge; 4-soil+sewage sludge; 5-soil+mineral sorbent; 6-soil+mineral sorbent; 7-soil+sewage sludge+mineral sorbent; 8-soil+sewage sludge+mineral sorbent. On the surface of bioreactors 2, 4, 6 and 8 the seeds of *Phalaris arundinacea* were also been introduced. Obtained results showed that, fertilization with sewage sludge causes a temporary increase in the content of organic pollutants such as PAHs in soil. The use of sorbents as a fertilization material may decrease the mobility of pollutants in the soil environment. Direct increase of soil sorption capacity by introducing mineral sorbents has a significant impact on the induction of biodegradation of PAHs in soil. The cultivation of crops such as *Phalaris arundinacea* has a positive effect on the biodegradation of PAHs in soil.

318

#### **Strategies for cleaning up ATRAZINE-polluted soils using Microbial Electromediating Cells (MERCs)**

A.D. Garay; K. Boltes Espínola, A. Esteve-Núñez, University of Alcalá Bioremediation is a cost-effective technology for treating polluted soils. However, the availability of suitable electron acceptors to sustain microbial respiration can reduce the microbial detoxification activity. The concept of using electrodes to overcome this metabolic limitation led recently to the concept of Microbial Electromediating Cells MERCs (1). In contrast with standard environmental applications as sedimentary Microbial Fuel Cells (sMFC), MERCs do not aim power production but to maximize biodegradation rates around the electrode by offering a never-ending electron sink. Our work demonstrates that natural population can be effectively stimulated by MERCs in order to bioremediate a soil polluted with the herbicide atrazine (2-chloro-4-ethylamino-6-isopropyl amino-1,3,5-triazine). Residual concentration of atrazine was ca. 6-fold lower in MERC-treated soil than in MERC-free soil after 2 weeks of assay. This effective

bioremediation task was confirmed by soil extraction followed by HPLC-DAD analysis. Furthermore, the effective removal of pollutants was supported by ecotoxicological analysis, based on algal growth assays, with a severe reduction in soil toxicity (ca. 30-fold) after 2 weeks of treatment leading to a non-toxic soil. Interestingly, MERC-free soil was still heavily polluted after this period, proving that MERCs can be an effective tool for removing organic pollutants from soil. (1) Rodrigo, J.; Boltes, K., Esteve-Núñez, A. Rodrigo, J., Boltes, K. and Esteve-Núñez, A. (2013) Microbial-electrochemical bioremediation and detoxification of dibenzothiophene-polluted soil. #### **Discussion - Open floor to audience**

J. Colbourne, University of Birmingham

We will start the discussion by proposing that our speakers and audience answer the question: Can OMICS deliver solutions in time to be of practical value to REACH and WFD? We aim to understand the position of the different stakeholders regarding this problematic, and propose to draw a guideline on how to proceed, with the different assays and novel technologies, in order to achieve a good integration of this data into Risk Management. Making it more useful for the policy makers and enforcement agencies, simultaneously, allowing the industry to move at a faster pace towards responsible innovation, and presenting the scientific community with clear goals a special note on time and cost effectiveness to meet these legislative and regulatory challenges.

## **Periphyton ecology and ecotoxicology: how much complexity and reproducibility are required to connect both perspectives?**

324

#### **Fungicide effects on stream benthic microbial communities: influence of substratum type**

F. Donnadieu, F. Rossi, P. Besse-Hoggan, C. Forestier, Université Blaise Pascal; J. Artigas,

Fungicides reaching stream ecosystems can show different capacities to adsorb onto benthic substrata, and thus, cause contrasting effects on their associated microbial communities. This study aims to evaluate the potential of tebuconazole (TBZ) adsorption onto submerged leaves and sand substrata and identify its effects on the biomass and functioning of microbial communities. An indoor stream channel experiment was designed to test TBZ effects on leaves alone, sand alone, and mixed leaves+sand substrata during five weeks. Weekly samplings evaluated TBZ effects ( $10.7 \pm 0.3 \mu\text{g L}^{-1}$ , average exposure concentration) on microbial biomass, diversity and activity (litter breakdown rates, sporulation rates and extracellular enzyme activities) of fungi and bacteria as well as the 7-day percentage of TBZ dissipation in channels. Results showed that TBZ significantly reduced fungal biomass (17-20 % with respect to controls) but increased the bacterial biomass (34-50 %) on leaves and sand incubated alone. TBZ significantly inhibited phenol oxidase activity (36 %) in sand microbial communities but not that on leaves. Differences in TBZ effects between leaves and sand communities were not explained by differences in TBZ adsorption between substrata but more likely were related to the different biomass accrual and structure of microbial communities. Mixing (leaves+sand) substrata tended to attenuate TBZ effects on microbial communities, and this was probably explained by the greater substratum surface area available for TBZ adsorption. This hypothesis was confirmed by the greater percentage of TBZ dissipation measured in (leaves+sand) channels. However, substrata mixture did not only dilute but modified TBZ effects in sand communities [increase of fungal biomass (14 %) and hyphomycete sporulation

rates (82 %)]. This result suggests that sand can eventually represent a suitable microenvironment for fungal development during TBZ contamination episodes. The present study shows the relevance of benthic substrata heterogeneity in determining the fate and effects of TBZ in agricultural streams, but also highlights the contrasting response between fungi and bacteria to cope with the fungicide.

325

#### **Arsenic toxicity effects to microbial communities in indoor experimental channels mimicking fluvial system**

A.M. Romani, University of Girona / Institut d'Ecologia Aquàtica; B. Tuuilaikhuu, University of Girona / Environmental Science; H. Guasch, Institute of Aquatic Ecology

This study aimed to evaluate the fate and effects of a long-term, environmentally realistic concentration of Arsenic (As) exposure on some of the biofilm functions in a simplified fluvial system including interaction between fish and biofilm. The presence of fish provides a high ecological realism through contribution of nutrients, since arsenic toxicity is more severe to nutrient starved periphytons. On the other hand, biofilm may also influence arsenic toxicity to fish due to adsorption, uptake and/or transformation of arsenic. Biofilm were exposed for 59 days to arsenic ( $120 \mu\text{g/L As}^{\text{V}}$ , nominal concentration) under the presence of fish (*Gambusia holbrooki*) with a biomass of  $27.95 \pm 3.7 \text{ g/m}^3$  in a recirculating system. Nutrient input from fish was calculated based on mass balance equation and compared with nutrient contents in the different compartments of the system: illuminated substrata, sediment, fish and water. Arsenic fate to the different compartments was also quantified and a set of biofilm endpoints related to community composition (algal groups), biomass growth (AFDW and Chl a) and microbial activity (phosphatase and  $\beta$  glucosidase) were examined. Fish had a significant contribution to phosphorus input, providing background P concentration. As mostly adsorbed to sediment (79.7%) leading to  $40.7 \mu\text{g/L As}^{\text{V}}$ , as calculated daily average exposure. On the other hand, As concentration in periphyton was higher ( $15.9 \pm 4.8 \text{ mg/kg}$ ), supporting the use of arsenic accumulation in periphytic biofilms as biomarker of As exposure in natural systems. As exposure inhibited the growth of diatoms, moreover, considering the relative fluorescence of the groups of algae: diatoms dropped off significantly and the percentage of green algae increased through time indicating a selective pressure towards the former. Total biomass of biofilm and chlorophyll a in the sediment, were affected by As, making the biofilm heterotrophic. Phosphatase activity were significantly lower in As treatment not demanding more phosphorus in this oligotrophic system, since autotrophic biofilm growth has already inhibited, also there is direct influence of As to the bacteria in the sediment. We conclude that exposure to arsenic at environmentally realistic concentrations and conditions will directly and indirectly affect the base (primary producers) of the aquatic food chain and its respective contribution to nutrient cycling impairing the normal functioning of the ecosystem.

326

#### **Bioavailability of mercury to natural freshwater periphyton and consequences on periphyton composition**

P. Dranguet, Institut Forel, University of Geneva / Section of Earth and Environmental Sciences Institute Forel and Institute for Environmental Sciences; S. Le Faucheur, Section of Earth and Environmental Sciences Institute Forel and Institute for Environmental Sciences; C. Cosio, Geneva University / Institute Forel Earth and Environmental Sciences; V.I. Slaveykova, University of Geneva / Section of Earth and Environmental Sciences Institute Forel and Institute for Environmental Sciences

Mercury (Hg) is a global contaminant, whose most dangerous form is methylmercury ( $\text{CH}_3\text{Hg}$ ) due to its biomagnification along the trophic chain. Periphyton is a complex community composed of autotroph and heterotroph organisms embedded in an abiotic matrix, which represents a pathway of Hg incorporation into the food chain. The present study aims to improve the understanding of Hg accumulation in natural biofilms along a gradient of Hg contamination and to explore the link between Hg speciation in water, its bioaccumulation and periphyton composition. Biofilm was grown on artificial substrates for three weeks and analysed for their composition by epifluorescence microscopy (for abiotic and biotic fractions) and by pyrosequencing (for taxonomy analysis). Inorganic Hg content was analysed w/o a washing step in order to discriminate total Hg ( $\text{Hg}_{\text{tot}}$ ) and Hg strongly attached to periphyton ( $\text{Hg}_{\text{n-ext}}$  and  $\text{CH}_3\text{Hg}_{\text{n-ext}}$ ). Physicochemical parameters of ambient waters at each sampling sites were also measured such as pH, anion/cation, dissolved organic matter and Hg concentrations. The dissolved  $\text{Hg}^{\text{II}}$  concentration was found to be higher in the most polluted site of Babeni ( $11.5 \pm 4.6 \text{ pM}$ ) compare to the control site ( $2.4 \pm 0.3 \text{ pM}$ ) and the other studied sites. However  $\text{CH}_3\text{Hg}$  concentrations were similar at all the studied sites ( $0.75 \text{ pM}$ ). Bioaccumulation of  $\text{Hg}^{\text{II}}$  was found to be positively linked with  $\text{Hg}(\text{OH})_2$  concentration in water. The proportion of the abiotic fraction was the highest in the most contaminated site ( $82 \pm 25\%$ ) compare to control site ( $24.1 \pm 9.2\%$ ). Pyrosequencing allowed us to observe an increase of four bacterial phyla *Verrucomicrobia*, *Firmicutes*, *Cyanobacteria* and *Bacteroidetes* along Hg gradient. A relationship was observed between Hg content in periphyton and its composition. Indeed when the biotic fraction increased, bioaccumulation of Hg decreased e.g in the control site, the biotic fraction was close to 90% and  $\text{Hg}_{\text{n-ext}}$  was  $166 \text{ pmol.g dw}$  whereas in Babeni, the biotic fraction was 44% and  $\text{Hg}_{\text{n-ext}}$  was  $973$

$\text{pmol.g dw}$ . Overall the results of the present study demonstrated the importance of both chemical speciation of Hg and periphyton composition in  $\text{Hg}^{\text{II}}$  and  $\text{CH}_3\text{Hg}$  accumulation by periphyton and have important implications for the use of periphyton in ecotoxicology.

327

#### **Adaptation of periphytic communities to copper and silver in an artificially-controlled exposure**

A. Autret, Irstea Antony UMR 6143 M2C CNRS / UMR MC CNRS; E. Uher; I. Friedel, Irstea Antony; T. Berthe, UMR 6143 M2C CNRS; L. Fechner, Irstea Antony; F. Petit, UMR 6143 M2C CNRS

Linking urban pollution to biological effects depends on the knowledge of biological-mechanisms. The microbial community provides a good level of biological organization to evaluate the toxic impacts on living organisms with different levels of sensitivity. River biofilms, which are at the basis of aquatic systems, allow assessing the toxic effects of micro-pollutants currently affecting aquatic systems. To this end, a microcosm approach has been developed to analyse how bacterial periphytic communities adapt to metals. River biofilms were exposed to two concentrations ( $10$  and  $100 \mu\text{g.L}^{-1}$ ) of Cu and Ag in mono- and bi-metallic conditions during five weeks. The adaptation of microbial communities was studied by the pollution-induced community tolerance (P ICT) approach, a short-term toxicity test based on  $\beta$ -glucosidase activity in order to assess heterotrophic biofilm tolerance. The adaptation of bacterial communities was also assessed by examining the bacterial diversity and also through the occurrence and expression of genes involved in the silver and copper efflux - such as *silA* (Ag), *copA* and *cusA* (Cu) by PCR and RT-PCR. The bacterial diversity was evaluated by sequencing the gene encoding 16 rRNA (V3-V4 fragment) using the Illumina Miseq technology. P ICT measurement was not carried out on two biofilms (no biofilm development for bi-exposure to  $100 \mu\text{g.L}^{-1}$  and weak  $\beta$ -glucosidase activity measured on biofilm exposed to  $100 \mu\text{g.L}^{-1}$  of silver). No P ICT effect was observed on the 5 other biofilms tested. The Ag10 biofilm expressed co-tolerance to Cu. *silA* was detected in all silver-exposed biofilms including the control biofilm, whereas *cusA* was only detected in Cu100 and bi-metallic biofilms. *copA* genes were absent in all biofilms. cDNAs related to *silA* were detected in all silver-exposed biofilms. The first interpretation of bacterial diversity (still on-going) has revealed the dominance of *Burkholderiales* in silver-exposed-biofilm community, corresponding to more than 50% of Ag100 biofilm diversity (mainly represented by the *Aquabacterium* genus). After an exposure to both metals, more than 50% of the bacterial community organization was represented by two orders corresponding to *Rhizobiales* (23%) and *Db1-14* (*alpha-Proteobacteria*; 30%). In conclusion, the bacteria periphytic communities seem to express *silA* gene when exposed to silver. Quantification of *silA* and *cusA* genes and the related cDNAs by qPCR will carry out the level of its occurrence and expression.

328

#### **Complex communities exposed to multiple pollutants: using passive sampler extracts in periphyton ecotoxicology**

S. Morin, Irstea / UR EABX; S. KIM TIAM, INRS - Eau, Terre et Environnement; S. Pesce, Irstea / UR MALY; A. Moreira, Irstea / Unité de recherche REBX; M. Eon, Irstea / UR EABX; C. Gardia Parege, EPOC-LPTC / UMR CNRS EPOCLPTC; H. Budzinski, University of Bordeaux / UMR EPOC Equipe LPTC; N. Mazzella, Irstea

In rivers, risk assessment requires taking into account both the complexity of contaminations (multiple substances at low concentrations), and the increasing demand for ecologically realistic biological endpoints used in toxicity testing. These issues can be tackled by coupling toxicity assessment using complex communities, such as periphyton (composed of microalgae, bacteria, fungi, protozoa, etc.), and complex contaminants like passive samplers extracts (PSE). Here we propose to review some recent progresses in ecotoxicology allowed by the joint use of PSE from POCIS (Polar Organic Chemical Integrative Samplers) and river periphyton. More specifically, we will present diverse experimental approaches, aiming: -at characterizing the "toxic potential" of waters and applying the pollution community induced tolerance -P ICT- approach to pesticide mixtures, -at identifying the compounds responsible for toxicity in the mixture (effect-directed analyses -EDA), and -at increasing the environmental realism in microcosm experiments by performing chronic low dose exposure to mixtures from PSE. We were able to detect P ICT in periphyton collected in rivers showing a gradient of increasing pesticide concentrations or at sites with different contamination profiles using toxicity tests with PSE from the field. From a pesticide mixture that proved to be toxic, we performed successive fractionation steps to identify, through an EDA approach, the substance(s) responsible for toxicity. In the mixture we used, however, no individual fraction was found to explain the impacts of the cocktails, whereas combinations of fractions did. This highlights the need to consider the "mixture issue" in environmental risk assessment. One way to improve mixture toxicity assessment is to implement chronic exposure experiments with PSE. We successfully performed artificial channel experiments using of PSE as a complex contaminant at low doses. The environmentally relevant concentrations tested drove community changes, in their structure (biomass, composition) as well as in their functions (enzymatic activities). Altogether, these encouraging results open wide perspectives for a more realistic risk assessment, from both biological and chemical points of view.

### Residue analyses of grey partridge's abnormal eggs: exposure to mixtures of plant protection products found in the real world

e. bro, ONCFS / Wildlife Research; J. Devillers, CTIS; F. Millot, ONCFS; A. Decors, ONCFS / SAGIR Network

Unintentional effects of current plant protection products (PPPs) use on non-target animals are little documented *in situ* on vertebrates living in cultivated farmlands. In this context, we are investigating the effects of grey partridge exposure to PPPs on its reproduction. This declining gamebird, typical of European cereal ecosystems, is especially exposed to PPPs during its whole life-cycle and appeared as a relevant focal species. The field study was carried out on 12 sites typical of French intensively cultivated farmlands where the grey partridge is still present as wild populations. 467 females were radiotracked daily. We detected 281 clutches (> 2500 eggs). All the biological material (pipped eggshells of hatched eggs as well as destroyed and intact eggs) was collected for a detailed description, some measures and further laboratory analyses. We recorded the following endpoints: clutch fate and cause of failure; clutch size; % of fertile eggs; % of dead embryos, stage of development and macroscopic anomalies; eggshell thickness. In a previous work, we determined the potential exposure of clutches to active substances during pre-laying, laying and incubation periods, based on the spatial and temporal coincidence between partridge presence in crop fields and pesticide application on those fields (known from a survey of 142 farmers). In addition, we performed residue analyses on 80-90 eggs using screening methods including ca. 500 active substances. After a short presentation of the whole study, we will briefly describe the field data for the most relevant reproductive endpoints, identifying suspicious anomalies in clutch or egg characteristics and quantifying them. Then we will report the results of residue analyses, focusing on the complex mixtures found in the real world and discussing the similarities and differences between potential and actual exposures. At this stage of our work, we supplemented our initial field dataset to develop *in silico* models to examine, and if possible to predict, the effects of bird exposure to active substances on the characteristics and output of their eggs. This research is funded by the *Pesticides – Ecophyto 2018* program of the French Ministry in charge of Environment.

### Are neonicotinoid insecticides associated with northern bobwhite declines in Texas?

M.A. Mora, H. Baldwin, Texas A&M University / Wildlife and Fisheries Sciences  
Neonicotinoid insecticides, primarily imidacloprid, thiametoxan, clothianidin, dinotefuran, and acetamiprid have been used in Texas since 1995. In 2009, the estimated use of imidacloprid in Texas, was close to one million pounds, and it was used primarily on corn, soybeans, and wheat. The regions with the heaviest applications were the Panhandle, Rolling Plains, Gulf Coast and coastal plain, and the Lower Rio Grande Valley. Studies in the U.S. and Europe have shown that neonicotinoid insecticides could have different effects on birds which could lead to population declines. During the first two weeks of their life, quail chicks in Texas feed primarily on arthropods (>80%), including leafhoppers, flies, bees, and wasps. Insects can accumulate significant concentrations of neonicotinoids. Moreover, Northern bobwhites can feed heavily on crop seeds (e.g. wheat, milo, corn, and soybean) during the fall-winter. Seeds treated with imidacloprid could possibly lead to reproductive abnormalities in birds. We compiled information on the use of neonicotinoid insecticides in Texas over the last 20+ years, using data from the USGS NAWQA database (<http://water.usgs.gov/nawqa/pnsp/usage/maps/>). We also compiled quail population data from Texas using the Texas Parks and Wildlife Department roadside survey data collected over the same time period. We correlated quail population trends with neonicotinoid insecticide use in Texas to establish possible cause-effect linkages. The results indicate a significant negative correlation between neonicotinoid insecticide use in Texas and quail population declines. We are currently conducting GIS analysis to more effectively determine the relationship between quail population changes and heavy neonicotinoid use in important agricultural areas in Texas. Additionally, data on tissues and crop contents of bobwhite quail collected all over the state will be examined and correlated with areas of heavy use of neonicotinoids in Texas.

331

### Identity of key amino acids in the AHR1 ligand-binding domain predicts avian sensitivity to dioxin like compounds: in vivo verification in European starlings

M.L. Eng, Simon Fraser University; J.E. Elliott, Environment Canada / Science Technology Branch; S. Jones, Thomson Scientific / Books Acquisition; T. Williams, Simon Fraser University; K.G. Drouillard, University of Windsor / Great Lakes Institute for Environmental Research; S.W. Kennedy, Environment Canada  
Avian species are highly variable in their sensitivity of to the embryotoxic effects of dioxin-like compounds (DLCs), and this variability in sensitivity can be predicted by the amino acid identity at two key sites within the ligand binding domain of the aryl hydrocarbon receptor 1 (AHR1). The domestic chicken (*Gallus gallus domesticus*) has been established as a highly sensitive species to the toxic effects of DLCs. Results from genotyping and *in vitro* assays predict that the European

starling (*Sturnus vulgaris*) is also highly sensitive to DLC toxicity. The objective of this study was to test that prediction *in vivo*. To do this, we used egg injections in field nesting starlings with 3,3',4,4',5-pentachlorobiphenyl (PCB-126), a dioxin-like PCB. Eggs were dosed with either the vehicle control or one of five doses (1.4, 7.1, 15.9, 32.1, 52.9 ng PCB-126/g egg). Eggs were incubated by parents until pipping, and then placed on an incubator to monitor hatching so that individual hatchlings could be attributed to specific eggs. Hatching success in vehicle-injected eggs was equivalent to unmanipulated starling eggs (94%). There was a dose-dependent increase in embryo mortality, and the LD<sub>50</sub> (95% CI) was 5.61 (2.33-9.08) ng/g. Hepatic CYP1A4/5 mRNA expression in hatchlings also increased in a dose-dependent manner, with CYP1A4 being more induced than CYP1A5. There was no effect of dose on morphological measures, and we did not observe any overt malformations. These results indicate that other than the chicken, the European starling is the most sensitive species to the effects of PCB-126 on avian embryo mortality reported to date, which supports the prediction of relative sensitivity to DLCs based on amino acid sequence of the ARH1.

332

### Wetlands receiving effluents of wastewater treatment plants: an ecological trap for waterbirds

J. López Perea, Instituto de Investigación en Recursos Cinegéticos / Unidad de Ecología y Ciencia Animal; J. Feliu, Instituto de Investigación en Recursos Cinegéticos; P.R. Camarero, UCLMCSIC; R. Mateo, U.C.L.M.-C.S.I.C. / Instituto de Investigación en Recursos Cinegéticos

The destination of the effluents of wastewater treatment plants in flat semiarid regions is frequently a natural or artificial wetlands that also helps in a tertiary treatment of the water, transforming some temporary wetlands into permanent lakes. This type of permanent lakes tends to eutrophication and then their high productivity makes them attractive for waterbirds feeding on aquatic invertebrates. However, this environment can also act as an ecological trap because of the higher prevalence of pathogenic bacteria and organic pollutants from treated sewage water coming from urban and industrial sources. The present work has been focused on the study on the presence of persistent organic pollutants in waterbirds from a wetland that receives the effluent of a wastewater treatment plant (Navaseca Lagoon) and how these pollutants affect their levels of plasma antioxidants compared with birds from non-polluted sites (Tablas de Daimiel National Park). Blood samples were collected of total number of 99 common moorhens (*Gallinula chloropus*) to determine plasma levels of vitamins (retinol and  $\alpha$ -tocopherol) and carotenoids (lutein) and blood concentrations of OC pesticides and PCBs. The most prevalent OCs in blood of common moorhen were o,p'-DDE, p,p'-DDE, HCB and  $\Sigma$ PCBs. Moorhens showed higher levels of PCBs in Navaseca than in Tablas de Daimiel National Park and a similar trend was observed for the other persistent pollutants. The levels of plasma retinol were higher in Tablas de Daimiel than in Navaseca Lagoon and a similar non-significant trend was observed for  $\alpha$ -tocopherol and lutein. Differences observed here in retinol levels could be associated with the exposure to persistent pollutants, in especial to PCBs. However, the low negative correlation found between retinol and PCBs may be explained by the contribution on this effect of other pollutants being accumulated in Navaseca lagoon like heavy metals or other organic pollutants or even by the presence of avian pathogens in the area. Our results indicate clear differences in the accumulation of PCBs and the retinol levels between the two study areas. Retinol has important roles in functions involved in the maintenance of the health status of animals. Birds attracted to these highly productive eutrophic wetlands that receive effluents from wastewater treatment plants may suffer negative impacts on their health due to the accumulation of persistent pollutants and the consequent retinol status unbalance.

333

### Pb shot ingestion, oxidative stress and carotenoid-based coloration in waterbirds from the Ebro delta, NE Spain

N. Vallverdu-Coll, Instituto de Investigación en Recursos Cinegéticos / Wildlife Toxicology; F. Mougeot, EEZA; M.E. Ortiz Santaliesra, Institute for Environmental Sciences University of Koblenz-Landau / Institute for Environmental Sciences; A. Lopez-Antia, Instituto de Investigación en Recursos Cinegéticos (IREC); J. Rodríguez-Estival, University of Calgary / Ecosystem and Public Health; R. Mateo, U.C.L.M.-C.S.I.C. / Instituto de Investigación en Recursos Cinegéticos

The ingestion of lead (Pb) shot constitutes the main cause of Pb poisoning in avifauna, but less is known about the sublethal effects and their consequences at a population level. We studied the relationship between Pb shot ingestion, oxidative stress and coloration in mallards from the Ebro delta. A total of 109 mallards were captured between 2008 and 2012, and blood samples were collected to analyze Pb concentration and  $\delta$ -aminolevulinic acid dehydratase ( $\delta$ -ALAD) activity. Malondialdehyde concentration (MDA), total and oxidized glutathione levels (GSht and GShtox), and activity of superoxide dismutase (SOD) and glutathione peroxidase (GPx) were quantified in red blood cells. Vitamins (retinol,  $\alpha$ -tocopherol) and carotenoids (lutein, zeaxanthin) levels were analyzed in plasma. Carotenoid-based coloration was studied by spectrophotometry, measuring beak yellowness in males, and leg orangeness in both gender. Blood Pb concentrations were lower in 2012 than in 2008-09 ( $p=0.008$ ), which can be related to the ban on the use of Pb shot in 2003. Blood Pb levels in 2012 were negatively associated with  $\delta$ -ALAD activity ( $r=-0.837$ ,  $p<0.001$ ). GPx activity ( $p=0.016$ ) and MDA ( $p=0.043$ )

levels were positively related to blood Pb concentration. A significant interaction between sex and blood Pb levels explained the variation in retinol ( $p=0.033$ ), GSHt ( $p=0.079$ ) and GSHox ( $p=0.017$ ) levels, with negative relationships in females and positive relationships in males. In females, leg orangeness did not vary with blood Pb levels. In males, leg orangeness ( $p=0.010$ ) and beak yellowness ( $p=0.008$ ) negatively correlated with blood Pb levels. Beak yellowness positively correlated with zeaxanthin ( $p<0.001$ ),  $\alpha$ -tocopherol ( $p=0.010$ ) and GSHox ( $p=0.073$ ) levels, and the association between blood Pb and coloration remained when controlling for these parameters (all  $p<0.017$ ). Although blood Pb levels decreased after the ban on Pb ammunition, Pb exposure still occurred in 2012, and affected several oxidative stress indicators and coloration in males, which is known to influence reproductive investment in mallards. Exposed females may have compensated Pb effects by investing antioxidants to counter oxidative stress, without compromising coloration. Males may have mobilized antioxidants to counter Pb-induced oxidative stress at expenses of coloration, reflecting the carotenoid-antioxidant allocation trade-off between the expression of sexual signals and the oxidative stress-sensitive functions.

### 334

#### Environmental and anthropogenic stressors and impacts on gulls

**S. Lacorte**, A. Bertolero, IDAEA-CSIC / Environmental Chemistry; E. Abad, CSIC / Dioxin Laboratory Environmental Chemistry Department; C. Porte, CSIC - IIQAB / Environmental Chemistry; S. Diez, CSIC-IDAEA / Environmental Chemistry; F. Santos, University of Barcelona / Analytical Chemistry  
Nowadays, many habitats are strongly affected by anthropogenic and environmental pressures which can affect the wellbeing of many species. This study is focused on the effects of environmental and anthropogenic stressors on gulls, considering effects that span from biochemical to population level. The species studied are the yellow-legged gull (*Larus michahellis*, YLG) and the Audouin's gull (*Larus audouinii*, AG). YLG is a common, large and opportunistic gull, with an omnivorous diet but often scavenges on refuse tips. On the other hand, AG is a medium size gull, endemic of the Mediterranean area, categorized as Near Threatened species on the IUCN 2012 Red List (IUCN, 2012). AG is a piscivorous species, considered a specialist in the capture of clupeiforms (pelagic fishes), but they can also feed on fishery discards and terrestrial preys. Whereas YLG is widely spread over the Iberian Peninsula, AG is concentrated in the Ebro Delta and Chafarinas colonies. In Spain, gull colonies are generally settled in National, Hunting Refugees and Natural Parks, areas with high levels of conservation and protection. However, gulls, and indirectly other species, are affected by multiple stressors that can induce effects at individual or population level. We have first determined the pressures in the National Park of Atlantic Islands, in Chafarinas Islands and in the Ebro delta Natural Park. The species studied were YLG and in the Ebro delta, we also studied AG. In each colony, we have collected gull eggs and eventually blood. The array of parameters studied were: Characterization of Persistent Organic Pollutants (POPs) in gull eggs; bioaccumulation; maternal transfer of contaminants; neurotoxicity; endocrine disruption; eggshell thinning; population effects. Gulls are affected by the human impact and by the environmental disturbances. Overall, it is important to carry out integrative approaches to determine the dynamics and effects of contaminants in birds by combining chemical characterization with biochemical and field analysis to identify compounds, concentrations and toxicological endpoints to better assess the real risk of contaminants. **Acknowledgement** – This study was financed by the Ministry of Environment of Spain (project from the National Parks 2012-768).

## Latest advances in passive sampling and dosing (III)

### 335

#### Chemical and toxicological screening of large rivers using mobile passive sampling

**B. Vrana**, Masaryk University, Faculty of Science, RECETOX / RECETOX Research Centre for Toxic Compounds in the Environment; F. Smedes, DELTARES / BGS; T. Rusina, Masaryk University / RECETOX Research Centre for Toxic Compounds in the Environment; K. Okonski, Masaryk University Faculty of Science / RECETOX Research Centre for Toxic Compounds in the Environment; L.J. Allan, Norsk Institutt for Vannforskning; M. Grung, NIVA; K. Hilscherova, Masaryk University, Faculty of Science, RECETOX / RECETOX Research Centre for Toxic Compounds in the Environment; J. Novak, Masaryk University / RECETOX; P. Tarabek, Water Research Institute; R. Grabic, University of South Bohemia in CB / Faculty of Fisheries and Protection of Waters, South Bohemian Research Center of Aquaculture and Biodiversity of Hydrocenoses; J. Slobodnik, Environmental Institute  
Organic pollutants are often present in the water column at trace concentrations that are difficult to detect when conventional low volume spot sampling of water is applied. We present a novel representative mobile passive sampling approach for screening of trace organic pollutants and their toxic potentials along large rivers. The concept was successfully applied in summer 2013 within the Joint Danube Survey 3. The application of temporally- and spatially- integrative passive sampling approach resulted in samples that provide a representative picture of pollution situation for eight defined stretches of the Danube River. Despite the low or sub- ng l<sup>-1</sup> concentrations of most organic pollutants present in the free dissolved

phase, passive sampling enabled to clearly identify spatial gradients of a broad range of organic pollutants in the water column, including PCBs, organochlorine compounds, PAHs, alkylphenols, selected polar pesticides and pharmaceuticals. In many cases, the integrative character of passive sampling allowed measurement of compounds down to pg l<sup>-1</sup> levels where methods based on low volume spot sampling of water applied in the previous Danube survey failed to detect them. The combination of passive samplers with bioassays presents a very promising approach for detection of various toxic potentials along the river and for identification of areas of concern for further investigation.

### 336

#### Pore water and accessible concentrations of hydrophobic contaminants in Danube sediments of the Serbian stretch estimated by multi-ratio equilibrium passive sampling

**T. Rusina**, Masaryk University / RECETOX Research Centre for Toxic Compounds in the Environment; K. Okonski, Masaryk University Faculty of Science / RECETOX Research Centre for Toxic Compounds in the Environment; B. Vrana, Masaryk University, Faculty of Science, RECETOX / RECETOX Research Centre for Toxic Compounds in the Environment; F. Smedes, DELTARES / BGS  
Freely dissolved concentration in pore water and the accessible/releasable concentration of hydrophobic contaminants in sediment are both relevant parameters for availability of contaminants and for uptake by organisms in sediment. These parameters were measured by multi-ratio equilibrium passive sampling, equilibrating sediments sampled in Danube river at 11 Serbian locations and silicone rubber passive samplers at largely differing sampler-sediment ratios. Low sampler/sediment ratios yield the concentration in the pore water (minor depletion of the sediment). Equilibrations at high sampler/sediment ratios yield the accessible concentration in the sediment, i.e. maximum depletion of the sediment. In the present work freely dissolved and accessible concentrations of polycyclic aromatic hydrocarbons (PAHs), organochlorine pesticides (OCPs), polychlorinated biphenyls (PCBs), musks and alkylphosphates were measured. The accessible fraction was calculated as the ratio of the accessible concentration and the measured total concentration in the sediments. For different classes of hydrophobic contaminants accessible fractions varied. The lowest accessible concentrations were observed for PAHs in average between 10-40%. By contrast PCBs were in majority of locations fully available. Detected musk compounds were often not fully available. The lowest pore water concentrations were detected for PCBs at the level of 1-3 pg/L demonstrating high sensitivity of the method.

#### Equilibrium passive sampling as a tool to study hydrophobic organic chemicals in the sediment pore water of the German Bight (North Sea) and Wadden Sea

**N.C. Niehus**, Hamburg University of Applied Sciences (HAW) / Department of Environmental Engineering; B. Brockmeyer, German Federal Maritime and Hydrographic Agency (BSH); T. Seiler, RWTH Aachen University / Ecosystem Analysis; H. Hollert, RWTH Aachen University / Institute for Environmental Research; G. Witt, HAW Hamburg / Department of Environmental Engineering  
Hydrophobic organic chemicals (HOCs) like polycyclic aromatic hydrocarbons (PAHs) and polychlorinated biphenyls (PCBs) are of high interest in terms of today's sediment risk assessment and particularly bioavailability, bioconcentration and baseline toxicity. Passive sampling allows to determine freely dissolved concentrations and actually describe the transfer from sediment into the water phase. Ex-situ solid phase micro extraction (SPME) as a passive sampling tool was applied to measure freely dissolved concentrations ( $C_{free}$ ) and chemical activities ( $a$ ) of PAHs and PCBs in sediment samples from the North Sea and Wadden Sea. In order to assess biological effects the two conventional bioassays FET and EROD assay were conducted for investigating ASE extracts of the North Sea samples. Additionally a passive dosing version of the FET using silicone O-Rings loaded with single PAHs was performed. The composition of  $C_{free}$  among the North Sea sampling stations was similar, and as a consequence also the chemical activities. Freely dissolved concentrations of PAHs and PCBs in North Sea sediments were rather low and ranged between  $0.79 \cdot 10^{-3}$  and  $1.34 \text{ ng/L}$ . Pyrene showed the highest concentrations in all samples. This suggests a special burden of pyrene, since it is less soluble than phenanthrene or anthracene, yet there is a higher concentration in the pore water. Compositions of  $C_{free}$  in Wadden Sea sediments were different from the North Sea because PCB concentrations were higher, especially PCB 153. ASE extracts in the bioassays gave higher effects for samples from near the Elbe estuary, while extracts of sediments from the open sea showed no effects. These findings are compatible with the higher concentrations near the Elbe estuary. Using silicone O-Rings in the FET as passive dosing devices was easy viable and showed a good reproducibility. Naphthalene, phenanthrene, anthracene and fluorene exhibited high mortality at saturation level while fluoranthene showed low and benzo[a]pyrene no effects. In order to investigate PAH mixtures in realistic compositions, a passive dosing FET using recreated North Sea / Wadden Sea pore water is currently conducted.

### 338

#### Field Assessment of Natural Attenuation Processes Using Passive Sampling Methods

D. Lin, Stanford University / Department of Civil and Environmental Engineering; E. Eek, NGI / Environmental Technology; A.M. Oen, Norwegian Geotechnical Inst. / Dept Environmental Engineering; Y. Cho, Stanford University / Department of Civil and Environmental Engineering; R.G. Luthy, Stanford University / Civil and Environmental Engineering

Passive sampling devices (PSD) have been applied to assess natural attenuation processes in-situ in a deep freshwater alpine lake. This lake was historically contaminated with DDT, and previous field assessments show that deposition of clean sediment promotes restoration of the contaminated lake by burying older, more contaminated sediment. Since studies have shown that freely dissolved aqueous concentrations of hydrophobic organic contaminants are better correlated with bioavailability compared to total bulk sediment concentrations, we developed a novel tripod porewater probe installed with polyethylene PSDs at 2.5 cm resolution to measure the aqueous concentration profile at the sediment-water interface. The compact design of the porewater probe minimizes disturbance to in-situ hydrodynamics and bioturbation activity that could influence mass transfer of DDT at the sediment-water surface. This makes the probe suitable to investigate the DDT activity gradient and DDT mass transfer across the sediment-water interface. The tripod frame and central probe is designed for deep water deployment, and was able to measure sediment porewater concentrations in water depths of 120 m. Aqueous DDT concentration profiles from the porewater probe are consistent with previous field assessments using sediment cores and sediment traps.

339

#### **Application of Passive Sampling for Measuring Dissolved Concentrations of Organic Contaminants in the Water Column at Three U.S. EPA Marine Superfund Sites**

R.M. Burgess, U.S. EPA / Atlantic Ecology Division; R. Lohmann, University of Rhode Island / Graduate School of Oceanography; J.P. Schubauer-Berigan, U.S. EPA; P.J. Reitsma, Narragansett Bay Commission; M.M. Perron, EPA; L.F. Lefkowitz, ARCADIS; M.G. Cantwell, Atlantic Ecology Division

At contaminated sediment sites, including U.S. EPA Superfund sites, it is critical to measure water column concentrations of freely dissolved contaminants to understand the complete exposure of aquatic organisms to hydrophobic organic contaminants (HOCs). Historically acquiring the freely dissolved concentration ( $C_{free}$ ) of HOCs was challenging. In recent years, passive sampling has been demonstrated to be an effective tool for determining  $C_{free}$  in the water column and in sediment interstitial waters. Currently, there is an effort underway encouraging remedial project managers (RPMs) at contaminated sites to use passive sampling to collect  $C_{free}$  data in order to improve site assessments. The objective of this investigation was to evaluate the use of passive sampling for measuring water column  $C_{free}$  for several HOCs at three U.S. EPA Superfund sites. Sites investigated included New Bedford Harbor, Palos Verdes Shelf and Naval Station Newport and the passive samplers evaluated were polyethylene (PE), solid phase microextraction (SPME), semi-permeable membrane devices (SPMD) and polyoxymethylene (POM). In general, the different passive samplers demonstrated good agreement with  $C_{free}$  values varying by a factor of two to three. This level of agreement was demonstrated, in particular, at Palos Verdes Shelf where elevated  $C_{free}$  determined by different types of passive samplers deployed in studies over several years varied by less than a factor of two (i.e., 320 to 460 pg/L for sum of polychlorinated biphenyls, PCBs). Further, at New Bedford Harbor, where conventional water sample concentrations were also measured (i.e., grab samples), passive sampler-based  $C_{free}$  agreed within a factor of two. These findings suggest that all of the samplers were experiencing and measuring similar  $C_{free}$  during their respective deployments. This evaluation demonstrates the utility of passive sampling for generating scientifically accurate water column  $C_{free}$  which is critical for making informed environmental management decisions at contaminated sediment sites.

#### **Potential of human POP levels for endocrine disruption - applying in-vitro passive dosing from silicone**

D. Gilbert, Aarhus University, Science and Technology Faculty / Department of Environmental Sciences; P. Mayer, Technical University of Denmark / Department of Environmental Engineering; A. Vinggaard, M. Pedersen, DTU Technical University of Denmark / National Food Institute

Persistent organic pollutants (POPs) accumulated in human tissue may pose a risk for human health by interfering with the endocrine system. A new partitioning-controlled dosing approach from silicone was applied to the in-vitro H295 steroidogenesis assay to test whether POPs in a mixture composition and at concentrations as found in humans can interfere with steroidogenesis. Silicone served as partitioning source for the test chemicals but at the same time functioned as sorptive sink for lipophilic hormones produced by the cells. The new method was compared to conventional solvent-dosing. A technical mixture of 4-nonylphenol isomers (4-NP) was used for method development, and finally a mixture of PCBs, PBDEs, HCB and DDT as identified in human silicone breast implants was tested. Regardless of the dosing mode, 4-NP altered the hormone production in a qualitatively similar dose-dependent manner. With the concentration of freely dissolved molecules in the exposure medium as dose metrics as a measure for the effective concentration, dose-response curves were moved toward lower concentrations by a factor of approx. ten relative to nominal concentrations in the

medium. The POP-mixture, when dosed from silicone, increased the production of progestagens and androgens with exception for testosterone, but not when co-solvent dosing was applied. The new silicone-based dosing approach was successfully established and allowed linking human silicone concentrations of POPs to altered hormone production in the human cell line H295.

## **Mercury Pollution: Chemistry, Remediation and Policy**

341

#### **Linking transcriptome response with mercury accumulation in the microalga *Chlamydomonas reinhardtii***

R. Beauvais-Flueck, Institute Forel Earth and Environmental Sciences; V.I. Slaveykova, University of Geneva / Section of Earth and Environmental Sciences

Institute Forel and Institute for Environmental Sciences; C. Cosio, Geneva University / Institute Forel Earth and Environmental Sciences

Mercury (Hg) pollution is a continuing hot topic for freshwater ecosystems protection. Understanding accumulation and effects of both inorganic (IHg) and methyl (MeHg) Hg forms in key organisms is essential to predict the risk they could represent for the aquatic environment. This study aims at investigating the link between internalized Hg concentrations and the expression of genes, obtained by high-throughput sequencing (RNA-Seq), in the microalga *Chlamydomonas reinhardtii*. Algal cells were exposed two hours in a simplified artificial medium spiked with series of inorganic Hg concentrations ( $1 \times 10^{-10}$ ,  $1 \times 10^{-8}$  and  $1 \times 10^{-7}$  M IHg) or methyl Hg concentrations ( $5 \times 10^{-11}$ ,  $5 \times 10^{-10}$ ,  $5 \times 10^{-9}$  and  $5 \times 10^{-8}$  M MeHg). At the end of the exposure, extracellular loosely bound Hg was distinguished from the intracellular Hg by rinsing cells with 1 mM EDTA + 1 mM cysteine, which allowed to measure intracellularly bioaccumulated total Hg or MeHg concentrations by the automatic mercury analyzer AMA254 or the MERX-MeHg System, respectively. Moreover, oxidative stress was assessed using the biomarker CellRox® and photosynthesis efficiency was evaluated by Fast Repetition Rate fluorometry and chlorophyll fluorescence measurement. Subsamples of algae from each biological triplicate were additionally harvested by centrifugation and frozen in liquid nitrogen, before RNA extraction and library preparation. Libraries were then sequenced on Illumina HiSeq2500. Although *Chlamydomonas* accumulated IHg and MeHg in a dose-dependent relationship (up to  $2.66 \pm 0.17$  amol<sub>THg</sub>/cell and up to  $0.59 \pm 0.08$  amol<sub>THg</sub>/cell intracellular concentrations, for IHg or MeHg exposed algae respectively), no oxidative stress nor photosynthesis deficiency were observed. However, differential gene expression analysis demonstrated that exposure to IHg induced up-regulation of genes involved in the amino acids metabolism and down-regulation of oxygen transport, whereas exposure to MeHg affected the cell cycle, with an up-regulation of microtubules and cell division linked genes, and induced divalent metal ion transport down-regulation. Several interesting genes were selected and will further be proposed as potential candidates for use as IHg and/or MeHg exposure biomarkers. This study finally showed that using transcriptomics in relation to metal bioavailability enables to detect toxic effects at low exposure concentrations, which could contribute interestingly in Hg environmental risk assessment.

342

#### **Biogeochemical Factors Regulating Mercury Cycling in a Tidal Estuary and Implications for Remedy Decision-Making: Berry's Creek Study Area, New Jersey USA**

B. Henry, Anchor QEA; D. Vlassopoulos, Anchor QEA LLC; D. Glaser, Anchor QEA; P. O'Day, University of California Merced; S.S. Brown, The Dow Chemical Company / Department of Toxicology

Berry's Creek is a tidal tributary of the Hackensack River in the northeastern United States with a long history of human impacts. PCBs and mercury (Hg) have been identified as contaminants of interest. The Berry's Creek watershed is currently the focus of investigation by a group of private companies and public agencies under the purview of the USEPA. As part of this process, a conceptual biogeochemical model was developed to provide a basis for understanding Hg bioavailability and informing decisions on remedial action. The conceptual framework accounts for key aspects of Hg partitioning (aqueous speciation, precipitation of mercuric sulfide, binding to organic matter), and methylmercury (MeHg) formation, demethylation and partitioning to sediment (net MeHg accumulation). A thermodynamic-kinetic reaction path model was constructed to simulate/explore relationships between total Hg and MeHg concentrations over a range of sediment conditions. Theoretical upper limiting values for MeHg concentrations in sediment are predicted by the model as a function of total Hg load and inorganic Hg partitioning mechanisms in sediment (sorption vs. solubility). Net MeHg accumulation less than the theoretical maximum is due to biogeochemical redox processes that suppress Hg methylation and/or enhance MeHg demethylation. The general nature of our model is empirically confirmed by comparison of model predicted limits with data for sediments covering a wide range of Hg concentrations and environments across the study area. Measured MeHg levels are commonly up to 2 to 3 orders of magnitude lower than upper limiting values and correlate with oxic or suboxic redox regimes characterized by nitrate and manganese(IV) reduction, not sulfate reduction. Sequential extraction analysis and bulk and micro-focused X-ray absorption near-edge spectroscopy (XANES) were also used to directly determine Hg availability and solid-phase Hg and sulfur (S) speciation in

Berry's Creek sediments. Metacinnabar was identified by bulk XANES as a significant component. S micro-XANES showed mixtures of reduced and oxidized S species. Sequential extraction analyses confirm that Hg sequestered in sulfide phases is less available for methylation. Our biogeochemical model provides a quantitative theoretically grounded framework for interpreting relationships between total Hg and MeHg levels across the study area with important implications for risk assessment and remedial approaches.

**Assessing forty years of mercury measurements in Mediterranean Sea biota**  
S. Cinnirella, CNR Institute of Atmospheric Pollution Research; P. Nicola, Institute of Atmospheric Pollution Research; D.C. Evers, D. Buck, Biodiversity Research Institute

Along the forty-year story mercury measurement in Mediterranean Sea biota, a number of techniques have been developed including more precise instruments for many assessments evaluating the impact of mercury pollution on human health and environment. Most of the study do not produced structured databases, which can improve regional assessments. To this end a wide literature survey was conducted, recognizing the necessity to document mercury concentrations in marine biota. Data were collected and archived data into a structured database under the Global Mercury Observation System (GMOS) Spatial Data Infrastructure ([www.gmos.eu/sdi](http://www.gmos.eu/sdi)). The analysis of such a large database show that it is challenging to assess the biomagnification of methylmercury because there is a lack of information on measurements at different trophic levels through the food web.

### 344

**Coping with mercury in a warmer ocean: tissue partitioning, speciation, and ecophysiological implications in seabass (*Dicentrarchus labrax*)**

A. Maulvault, IPMA, I.P. / Division of Aquaculture and Seafood Upgrading; P. Anacleto, Portuguese Institute for the Sea and Atmosphere / Division of Aquaculture and Upgrading; A. Lopes, Faculdade de Engenharia - Universidade do Porto / LEPAE Laboratório de Engenharia de Processos Ambiente Biotecnologia e Energia; T. Repolho, R. Rosa, Faculdade de Ciências da Universidade de Lisboa / MARE Marine and Environmental Sciences Centre; P. Pousão, IPMA Portuguese Institute for the Sea and Atmosphere; M. Diniz, Centre of Fine Chemistry and Biotechnology (UNL) Lisboa; A.M. Marques, Portuguese Institute for the Sea and Atmosphere / Division of Aquaculture and Upgrading  
Anthropogenic activities have led to great environmental challenges: remarkable chemical contamination and dramatic climate change. Both factors strongly affect marine ecosystems and are expected to worsen in the future, threatening consumers' health and marine species' welfare and survival. It is unknown how marine organisms will cope with the exposure to chemical contaminants under climate change. Among chemical contaminants, methylmercury (MeHg) is of special interest, because it is highly neurotoxic, bioaccumulable and biomagnifiable throughout the aquatic food chain, and its presence in seafood is still not regulated. Thus, this contaminant is also of particular interest from the public health point of view, as the consumption of seafood is one of the main sources of human exposure to MeHg. The present work aimed to investigate, for the first time, the effect of global warming on tissue partitioning and speciation of Hg, using seabass (*Dicentrarchus labrax*) as model organism, and assess the organism ecophysiological consequences. Data clearly showed that temperature strongly influences Hg bioaccumulation, speciation and tissue partitioning. Moreover, synergistic effects of ocean warming and Hg exposure revealed widespread impairments in the enzymatic machinery, and that mercury uptake, mostly in the form of MeHg, was positively correlated with the metabolic rates. Considering the deleterious impacts of climate change and chemical contamination, the present work suggests great biological challenges to marine populations in the NE Atlantic coastal ecosystems in the future, as well as an increased risk of human exposure to MeHg through the consumption of seafood.

### 345

**Declining Mercury in Landlocked Char in High Arctic Lakes: Response to global emissions or impacts of climate change?**

D.C. Muir, Environment Canada / Aquatic Contaminants Research Division; G. Koeck, Institute for Interdisciplinary Mountain Research; X. Wang, Environment Canada; K. Hudelson, University of North Texas / graduate student; P.E. Drevnick, Inrs-Ete, Université Du Québec / INRS-ETE

As the only top predators in most high latitude Arctic lakes, landlocked char are good indicators of changes in inputs of mercury (Hg) and bioaccumulation of methyl Hg. Landlocked Arctic char collected have been annually for the past 10 or more years from 5 small lakes (2) near the community of Resolute Bay on Cornwallis Island (Amituk, Char, North, Small, and Resolute) at 75 deg N and from Lake Hazen in Quttinirpaaq National Park on Ellesmere Island (82 deg N). Sampling was carried out in late July or early August using gill nets (net size 32 mm). Collection numbers have typically ranged from 7 to 25 adult fish (>200 g) per lake. Temporal trend analyses and multiple linear regression modelling was conducted with length-adjusted Hg concentrations and climate variables. Statistically significant declines in length adjusted mercury concentrations in char muscle were found from Amituk, Char, North, and Resolute lakes. Annual percent declines ranged from 5.5% (Lake Hazen; 2005-14) to 19% (Char Lake; 2005-12). Small Lake, the smallest and shallowest lake, was the only one with an increase in

concentrations in more recent years, however, the increase (2.3%) was not statistically significant. Prior to the mid-2000s Hg concentrations in char from these lakes had appeared to be steady or increasing. Results of the multiple linear analysis for each lake showed that prediction equations shared the common factor Mean Summer Temperature (MST; June & July). In each prediction equation, MST was negative, indicating that higher summer temperatures lead to decreased Hg in char. For Resolute Lake which has 16 years of data, the prediction equation was:  $[Hg] = -0.74 + 0.0013 * (\text{Prev. Fall ppt}) - 0.049 * \text{MST}$  ( $r^2 = 0.63$ ;  $P < 0.002$ ). Precipitation and annual snow were important factors in Resolute and Char Lakes, perhaps indicating that Hg deposited in the watershed is washing in due because of the snow and rainfall. The summer temperature term was negative in each model, indicating that higher summer temperatures will result in lower Hg concentration in char. Evans et al. (ES&T 2013) also found this term was consistently negative for Hg in lake trout. Methyl Hg elimination rates in salmonids are highly and positively correlated to water temperature ( $r = 0.77$ ,  $p < 0.0001$ ) [12]. Thus elimination of Methyl Hg during warm summers could account for the negative relationship between Hg concentration in char and MST.

### 346

**NICOLE Mercury Working Group: Risk-based Management of Mercury-Impacted Industrial Sites**

O. Phipps, ERM / Contaminated Site Management; R. Jacquet, Solvay SA / European Rehabilitation Management Group  
The Network for Industrially Contaminated Land in Europe (NICOLE) Mercury Working Group ([www.nicole.org](http://www.nicole.org)) will publish in early 2015 a guidance booklet to share case studies and best practice related to the characterisation and risk-based management of industrial sites impacted by Mercury (Hg). NICOLE prepared the guidance booklet in response to recent regulatory developments to share up-to-date research, case studies and best practice for the characterisation and risk-based management of industrial sites impacted by Mercury. The booklet draws upon over 50 published references, including Governmental guidelines and research papers, together with technical papers presented at the Mercury Technical Workshop organised by NICOLE in Brussels (December 2012) and the ImaHg publication produced by the SNOWMAN Network. In addition, case studies are included in the booklet prepared by industrial operators and service providers. An overview of recent legislative developments and a summary of Hg chemistry and fate & transport are provided, followed by the presentation of best practice for the risk-based management of Hg-impacted industrial sites, including characterisation, risk assessment, remediation and long-term risk management. The booklet concludes with Best Practice recommendations, initially for site characterisation and risk assessment and then for remediation and long-term site management. The presentation will share recent case studies and experience (good and bad) in the characterisation and risk-based remediation/management of Hg-impacted industrial sites. Particular focus will be given to the cost-benefit assessment of waste disposal facilities, in-situ and ex-situ stabilisation techniques and soil sorting and washing approaches. Key uncertainties and pitfalls to be aware of during site characterisation and remediation works will also be shared. The presentation will also highlight the key Health & Safety considerations and mitigation measures during the characterisation and remediation of Hg-impacted sites.

## Towards a reliable environmental impact assessment of personal care products

### 347

**Exposure to environmental contaminants: Personal Care Products bioaccumulation in human placental tissue**

J. Valle-Sistac, IDAEA-CSIC / Environmental Chemistry; D. Molins-Delgado, Environmental Chemistry; M. Diaz, L. Ibañez, Hospital Sant Joan de Déu / Endocrinology; S. Diaz-Cruz, IDAEA-CSIC / Environmental Chemistry; D. Barcelo, IIQAB-CSIC / Institute for Environmental Assessment and Water Research

Last decade, ingredients in personal care products (PCPs) have been described as chemicals of increasing environmental concern because of their toxicity, persistence, bioaccumulation, and ubiquity in the environment. PCPs are produced in extremely large quantities, thousands of tons per year. Parabens (PB) and UV filters (UV-F) are chemicals widely used as preservatives and sun blocking agents, respectively by personal care products, pharmaceutical and food industries. Many studies show the tendency of UV-F to bioaccumulate in living organisms due to their lipophilicity and stability versus biotic degradation [1, 2]. The ubiquity of these compounds in the environment and even human fluids [3-5] makes necessary further studies to fill the current knowledge gap. This study aims to provide evidence of the bioaccumulation of the environmental contaminants UV-F and PB in humans. The work describes the development, validation and application of an analytical method for multiclass determination of selected UV-F and PB based on high-performance liquid chromatography-quadrupole-linear ion trap-tandem mass spectrometry (HPLC-QqLIT-MS/MS) in women placental tissue. Target compounds were selected by their endocrine disruption activity and frequency of detection in the environment, i.e. benzophenone-1 (BP1), benzophenone-2 (BP2), benzophenone-3 (BP3), benzophenone-4 (BP4), 4-hydroxybenzophenone (4HB), methylparaben (MPB), ethylparaben (EPB), propylparaben (PPB), butylparaben

(BPB), and benzylparaben (BePB). LODs ranged from 0.001 to 0.067 ng/g fw and LOQs ranged from 0.020 to 0.225 ng/g fw. Recovery rates for spiked samples ranged from 51 to 144%. This method was satisfactory applied for the determination of PCPs in placental tissue samples, being determined for the first time BP4 and BePB in this biological matrix. **References** 1. ### 348

#### **Flooding effect on the distribution of personal care products in detrital aquifers. Case study: Guadalete River basin (SW, Spain)**

*e. corada*, N. Torres-Fuentes, University of Cadiz / Physical Chemistry; M.G. Pintado-Herrera, University of Cadiz; L. Candela, Polytechnic University of Catalonia; M. Paniw, University of Cadiz; E. Gonzalez-Mazo, University of Cadiz / Physical Chemistry; P. Lara-Martin, University of Cadiz  
Presence and distribution of personal care products (PCPs) and other emerging contaminants in aquifers are controlled by changes in their inputs. In this sense, storm events are of major importance in areas subjected to water scarcity, especially if combined sewer systems are used. The present study is focused in the region of Guadalete River basin (SW, Spain), where reclaimed water and sludge from local WWTPs are occasionally used for irrigation of golf courses and fertilization of crops, respectively. Combined sewer overflows (CSOs) also occur in this zone when sporadic heavy rainfall events exceed the capacity of the sewage treatment facilities, as well as severe pollution episodes in specific parts of the basin due to uncontrolled sewage spills. The sampling was carried out in three different campaigns at dry (March 2007) and rainy (April and December 2010) seasons along Guadalete river and 30 wells over its alluvial aquifers and the nearby Jerez de la Frontera aquifer. Results showed minimum concentrations for synthetic surfactants in surface waters during the first sampling: Linear alkylbenzene sulfonates (LAS), the most worldwide used surfactants, showed highest values ( $15$  to  $2770 \mu\text{g L}^{-1}$ ), followed by alkyl ether sulfates (AES, widely used in personal care products such as shampoos and lotions) ( $5$  to  $70 \mu\text{g L}^{-1}$ ) and the more hydrophobic alcohol ethoxylates (AEOs, used in household and industrial detergents) (from  $5$  to  $50 \mu\text{g L}^{-1}$ ). Regarding groundwater, the trends in terms of surfactant concentrations were similar to that previously observed for surface water samples. Therefore, the lowest values were measured during dry weather conditions ( $< 37.4 \mu\text{g L}^{-1}$ ), whereas the contamination of groundwater became more intense in December 2010 as the heavy rain caused the river to overflow and land was covered with water during several days before the sampling took place. Regarding other PCPs, 7 out of 40 were detected in surface waters: the most abundant fragrances, OTNE and galaxolide (up to  $6540$  and  $2748 \text{ ng L}^{-1}$ , respectively), followed by tonalide (up to  $259 \text{ ng L}^{-1}$ ). Triclosan (an antimicrobial) and UV filters (EHMC and benzophenone 3) were present at lower concentrations ( $< 150 \text{ ng L}^{-1}$ ). With respect to groundwater, most of them were detected only in Jerez de la Frontera aquifer, where a synthetic fragrance, OTNE, was predominant over the rest of target compounds (up to  $1285 \text{ ng L}^{-1}$ ), followed by benzophenone 3 and EHMC (both sunscreen products) ( $< 500 \text{ ng L}^{-1}$ ).

### 349

#### **Constructed wetlands: a barrier against discharge of personal care products in water environment**

P. Verlicchi, University of Ferrara / of Engineering; E. Zambello, University of Ferrara / Engineering  
In recent years, the issue of personal care products (PCPs) in wastewater has become a major concern as these substances can provide adverse effects to both human health and environment. Common wastewater treatments are not designed to deal with these compounds and data of their removal efficiencies are still scarce. Constructed wetlands (CWs) are very commonly used for treating domestic wastewaters all over the world. This study is an overview of the occurrence of a wide spectrum of PCPs in the influent and effluent of different types of CWs, including free water surface systems, as well as horizontal and vertical subsurface flow beds. CWs acting as primary, secondary or tertiary steps as well as CWs in hybrid systems were analysed and the corresponding removal efficiencies discussed. This study is based on about 40 peer reviewed papers referring to investigations carried out in Europe (64 %), America (28 %) and Asia (8 %). Included PCPs belong to the following classes: antioxidants, antiseptics, deodorants, flame retardants, insect repellents, plasticizers, sun screen products, fragrances and surfactants. PCP removal mechanisms (sorption, biodegradation, photodegradation and volatilization) were investigated as well as the influence on the removal efficiencies of the main CW design parameters (i.e. bed depth, filling material, presence of vegetation), operational (hydraulic load and retention time, feeding mode, redox conditions) and environmental conditions (temperature, rainfall). In secondary systems the highest average removal values were found for the hydrocinnamic acid (99 %) and methyl dihydrojasmonate (MDHJ, 95 %), in polishing ones for triclosan and some fragrances ( $> 70$  %). A release was observed

for a group of surfactants for which the formation, due to the degradation of others, is faster than their removal. An analysis of the effluent concentrations could provide, together with eco-toxicological data, an estimation of the impact that these compounds could have on the environment. CWs might represent a reliable and feasible treatment which is able to control and reduce the spread of PCPs in the aquatic environment (with limited operational costs) thanks to the different and simultaneous removal mechanisms occurring within these systems and their buffer capacity. These systems could be adequate for the treatment of wastewater in small communities that are not collected to the sewage network.

### 350

#### **QSAR Modeling and further priority setting of Personal Care Products**

S. Cassani, University of Insubria / DiSTA; F. Marzetta, University of Insubria / QSAR Res Unit Environ Chem Ecotox Department of Theoretical and Applied Sciences DiSTA; P. Gramatica, University of Insubria / DiSTA  
Nowadays, Personal Care Products (PCPs) and their ingredients are widely and daily used all over the world, often to improve human life and quality of products, and therefore to give benefits in everyday life. During the last years, PCPs became chemicals of recognized increasing environmental concern, mainly because they are detected in quantifiable amounts in water compartments and thus may harm aquatic life; some of these products contain endocrine disrupting compounds, and many of their other adverse effects are unknown. Additionally, data on persistence and toxicity are lacking and the overall environmental behavior needs to be investigated. PCPs show highly heterogeneous chemical structures and different properties. Due to this high variety and to the big number of end-points that should be studied, it is very important to have tools able to quickly highlight the most dangerous compounds, focusing the experiments only on the prioritized chemicals. The determination of all the requested properties is a long and difficult task. In silico tools, like Quantitative Structure-Relationship (QSAR) models, can predict missing data for the unknown activities and properties necessary to prioritize existing or not yet synthesized chemicals. In this study, we have modeled with QSAR different properties of PCPs, useful for their environmental characterization and to evaluate their impact on biota and potential PBT (persistence, bioaccumulation, toxicity) behavior. More than 500 chemicals, such as flavor and fragrance agents, hair dyes ingredients, phthalates and sunscreen agents have been modeled and screened for some environmental physico-chemical properties (e.g. Koc, vapor pressure and water solubility), acute toxicity on *Pimephales promelas* and cumulative PBT behavior. New local QSARs for PCPs have been developed and the models show good parameters regarding internal and external validation. The proposed screening has been performed by these new specific QSARs, by global models already included in the QSARINS software and by different web tools. The predictions were combined by Principal Component Analysis (PCA), to screen PCPs for their environmental properties. The results are a valid help for the understanding of the behavior of hundreds of PCPs, assessing their environmental impact, and for the reduction of experimental tests. A priority list containing the potentially most hazardous PCPs ingredients is proposed.

### 351

#### **Screening Level Environmental Risk Assessment (ERA) of Cosmetic Ingredients in the USA**

I. Davies, Personal Care Products Council / Science  
The Personal Care Products Council's (PCPC) environmental program recently began the development of a new ERA framework for cosmetic ingredients in North America. To begin with, around 7000 ingredients were identified as being in use across all cosmetic formulations. These ingredients were subsequently divided into a number of broad chemical categories. This initial exercise allowed the PCPC to assign screening level assessment strategies to each group of ingredients. One of these groups, discrete organic ingredients (both neutral and charged) was chosen to undergo a series of aquatic screening level assessments. As this group is widely used and disposed of chiefly *via* a "down the drain" exposure scenario, prioritizing discrete organic materials for aquatic screening was justified. Within this assessment, a network of *in silico* models was developed to estimate the potential removal of cosmetic ingredients from wastewater treatment. The models used were based the work of Salvito *et al.* (2002). Concurrently, acute aquatic toxicity was conservatively predicted by ECOSAR models from within the USEPA's EPISuite toolbox. Overall tonnages of cosmetic usage were estimated using a "market forensics" approach (DeLeo *et al.*, 2011) and industry survey data. From these combined approaches, an MST (maximum sustainable tonnage) value was derived for each cosmetic ingredient. This represents the total concentration of an ingredient which can be present in the environment without causing an adverse ecological effect. This value was then compared to total usage (of an individual ingredient) so that a risk ratio (similar to a traditional PEC: PNEC) could be calculated and assessed on an ingredient by ingredient basis. Other screening methods were developed for the initial evaluation of other ingredient types, such as polymers. Once a screening level assessment has been conducted ("tier I" of the framework) certain ingredients will then enter a second tier of assessment ("tier II"). In addition, a number of other prioritization schemes were developed, such as use of VCRP (Voluntary Cosmetic Reporting Program) data.

#### **Are natural substances toxic to the aquatic environment?**

U. Klaschka, University of Applied Sciences

Natural substances enjoy great public acceptance in personal care products, as well as in medicine. Many of them are complex mixtures of compounds belonging to various chemical substance classes, and some constituents are known for their potent physiological effects. As the discharge of personal care products is mainly via WWTP into the aquatic environment, the question is whether they exert negative effects on aquatic organisms. Hazard assessment via classification and labelling is a straightforward first approach to answer this question. It is also a precious step in the prioritization process for risk assessment. Natural substances appearing in the "inventory ..... of ingredients employed in cosmetic products" (INCI list) were compared with the entries in the C&L inventory, which is the official European database of classification and labelling information on notified and registered substances received from manufacturers and importers according to the CLP-Regulation EC 1907/2006. Out of around 1400 natural substances in the INCI list, 655 appear in the C&L inventory with 369 natural substances being classified as hazardous substances. 185 substances are classified due to their negative effects on the aquatic environment with 184 for long lasting effects. (H400 is based on data for acute toxicity only, whereas H410, H411, H412 and H413 are based on data on acute and chronic toxicity, on degradability or on the potential for bioaccumulation.) Even if production volumes are not known, the number of notifiers might be used as an indication in the prioritization process. Answers to the following questions are addressed: Which of the relevant natural substances of the INCI list are labelled and classified as dangerous to the environment? Which are relevant chemical constituents and which are their functions in personal care products? Many natural substances used in personal care products are naturally toxic and demand a prudent handling and sensible regulations.

## Leaving the comfort zone. The challenge of measuring nanoparticles in complex matrices

353

### Single Particle ICP-MS (SP-ICP-MS) For the Detection of Metal-Based Nanoparticles in Environmental Matrices

C. Stephan,

The use of nanoparticles in consumer products is showing a tremendous increase over time. The National Institute of Standards and Technologies reported that nanotechnology-based consumer products are currently entering the market at a rate of 3 to 4 per week, and it is estimated that \$2.6 trillion in manufactured goods will contain nanotechnology in 2014[1]. In spite of their beneficial properties, possible risks for humans and the environment need to be thoroughly investigated, and multiple key characteristics must be assessed. Detailed information about the quantity, shape, size, size distribution, structure, composition, surface charge and functionality need to be studied and addressed in order to perform an appropriate and reliable risk assessment. This work presents Single Particle Inductively Coupled Plasma Mass Spectrometry (SP-ICP-MS) as a tool in assessing the fate of engineered nanoparticles in environmental sample types, from tracking transformation/dissolution in surface water to bioaccumulation in *L. variegatus*, a species of aquatic worm [2,3,4]. The technique allows for the differentiation between ionic and particulate signals, measurement of particle sizes and size distribution, and assists in monitoring agglomeration. ### TRACKING NANOMATERIALS THROUGH THE LAUNDRY WASH CYCLE: RELEASE, DISSOLUTION AND COMPLEXATION

D.M. Mitrano, EMPA Technology & Society Lab / Environmental Risk and Management; B. Nowack, EMPA

In the context of assessing the potential risks of nanomaterials, a lifecycle approach (covering production, use and disposal of the nanomaterial or nano-product) represents a wholistic view of their potential impacts. Considering nanomaterial life cycles are determined by application within a product, relevant exposure scenarios and particle aging/transformations are strongly dependent on the life-cycle of nano-enhanced products themselves. For example, nanomaterials embedded in textiles would transform after exposure to oxidants and detergents during washing. Building on previous results which demonstrated the quantity and general size fractions of various silver additives released from textiles, we further characterized specific nanoparticle properties in the laundry wash cycle. Using a number of different liquid and powdered commercial detergents, washing studies were performed with nanoparticles suspended in wash solution or released from laboratory prepared textiles with known nanoparticulate additives to better understand particle release, (change to) particle size distribution, dissolution, re-precipitation (i.e. "new" particle formation) and complexation of manufactured nanomaterials to particulate matter in the washing solutions, such as zeolite. Au

NPs were used as a « tracer » through the system, since it is less reactive or prone to dissolution, to ensure analytical characterization techniques did not distort particle size or number concentrations throughout the tests. TEM and EDX analysis were performed to observe morphological and chemical changes to the particles after washing. Single particle ICP-MS (spICP-MS) was used to build a size distribution of particles in solution and detect complexation with larger floc material in the washing solution. When various conventional and nano materials were washed under standardized washing conditions, similar particle forms were detected regardless of the starting material. In contrast, varying the washing solution chemistry was found to dictate the extent and rate of dissolution, in addition to various surface chemistry changes detected depending on the concentration of bleaching agent. These studies help to further the understanding of nanomaterials through the product life cycle and give a better indication of how nanomaterials will be aged and transformed over time during regular nano-enhanced product use, not just in laboratory studies.

355

### Environmental leaching of nanoparticles from a consumer product and their detection by single particle ICPMS

F. Von der Kammer, Vienna University / Department of Environmental Geosciences; J. Navratilova, A. Gondikas, University of Vienna / Environmental Geosciences; T. Hofmann, University of Vienna / Department of Environmental Geosciences

The increased use of products containing nanoparticles will inevitably lead to their release into environment. Currently, the most commonly used nanoparticles in consumer products are metal oxide nanoparticles. Single particle ICPMS (spICPMS) has already showed a great potential for tracing silver nanoparticles in the aquatic environment, and it is the most promising technique for routine analysis of metallic nanoparticles in environmentally relevant concentration levels (ng/L). The biggest challenge in spICPMS analysis is to achieve the lowest particle size detection limit which is directly related to the detection limit, what puts high demands on the ICPMS instrumentation. In our study the triple quadrupole ICP-MS in single particle mode is employed to trace potential release of iron oxide nanoparticles from a consumer product into the simulated aquatic environment.

356

### Detection of engineered cerium oxide nanoparticles in soil extracts

A. Praetorius, University of Vienna / Department of Environmental Geosciences; S. Wagner, University of Vienna / Department of Environmental Geoscience; W. Fabienke, M. Velimirovic, University of Vienna / Department of Environmental Geosciences; E. Neubauer, University of Vienna / Environmental Geosciences; R. Kaegi; F. Von der Kammer, Vienna University / Department of Environmental Geosciences; T. Hofmann, University of Vienna / Department of Environmental Geosciences

Engineered cerium oxide nanoparticles (CeO<sub>2</sub> NPs) are expected to be released to the environment during their application as e.g. diesel fuel additives or automotive catalytic converters. There is a clear need to quantify CeO<sub>2</sub> NPs in environmental matrices in order to assess their potential risks, but the detection of engineered CeO<sub>2</sub> NPs in complex natural media is very challenging due to the low expected CeO<sub>2</sub> NP concentrations and the comparatively high background of Ce-containing minerals of similar size range. We here present a new analytical method, based on single particle (sp) ICP-MS analysis for identification and quantification of engineered CeO<sub>2</sub> NPs. We expect pulse signals of natural Ce-containing particles to be low and to not represent the true size of the particle detected by the sp-ICP-MS. In contrast, engineered CeO<sub>2</sub> NPs will appear as a spike which is significantly higher than the background signal and can be used to determine the mass and number concentration as well as the particle size of the CeO<sub>2</sub> NPs. Our hypothesis was tested with a set of experiments under increasingly more complex (and realistic) conditions. More specifically the following combinations of engineered CeO<sub>2</sub> NPs (Sigma Aldrich, CeO<sub>2</sub>

### Detection and quantification of nanoparticles in aqueous matrices by means of field flow fractionation and mass spectrometry

P.S. Bauerlein, KWR / Analytical and Environmental Chemistry; P. Herrero, Universitat Rovira i Virgili; E. Emke, KWR Watercycle Research Institute; E. Pocurull, R. Marcé, Universitat Rovira i Virgili; P. de Voogt, University of Amsterdam / IBED

Because of their chemical and electrical properties fullerenes have been widely applied in organic photovoltaic cells. In such commercial products especially modified fullerenes are used due to their increased solubility and better electronic properties compared to "normal" C<sub>60</sub>. The fate of these manufactured nanoparticles has been increasingly studied for their potential risks to the environment and human health. Detection and characterisation of the molecules is already possible. However, analysis of fullerene clusters in complex aqueous matrices is still not straightforward. Aim of the present work is to develop and optimise a method that allows the detection, size determination and quantification of fullerenes (and their clusters) in aqueous (complex) matrices by means of Orbitrap MS coupled to an FFF. For size determination a MALS detector is used. The FFF was coupled directly to the APPI interface and toluene was introduced into the APPI device via the auxiliary gas inlet. Toluene is necessary for ionization enhancement of

fullerenes. The flow rate was kept low (0.1 mL/min) using a slot pump. To separate the fullerene clusters in the FFF, several eluents were tested. A solution of 0.05% (v/v) % NH<sub>4</sub>OH was identified as a good eluent for the separation of three different fullerenes (C<sub>60</sub>, [6,6]-phenyl-C<sub>61</sub> butyric acid methyl ester ([60]PCBM) and [6,6]-(bis)phenyl-C<sub>61</sub> butyric acid methyl ester ([60]bisPCBM)). The size distribution received with this eluent coincides with literature values, the FFF theory and a calibration curve. This developed method for fullerenes was used to analyse different water types spiked with fullerenes. Different size distributions for fullerenes in MilliQ, drinking water, influent and effluent were found. It is obvious that the water matrix does effect the size of the clusters significantly.

#### Investigating nanoparticle transformation in situ in the environment through the use of nIDDs

E. Lombi, University of South Australia / Centre for Environmental Risk Assessment and Remediation; M. Khaksar, University of South Australia; R. Sekine, E. Donner, University of South Australia / Centre for Environmental Risk Assessment and Remediation; D.F. Jolley, University of Wollongong; K. Vasilev, University of South Australia / Mawson Institute; S. Kirk, US EPA  
Over the past two decades, extremely rapid progress in nanomaterial research and development has been met by equally rapid commercialisation of new products and technologies. As a result, manufactured nanoparticles (sub-100 nm scale) are increasingly released, both directly and indirectly, to the environment. Unfortunately, our understanding of the fate of manufactured nanomaterials in the environment is extremely deficient. In particular, the transformation of nanoparticles under natural conditions is a very challenging area of research due to the environmental low concentrations that can be expected at present time. In this study we report on the development and testing of a device, nano in situ deployment device (nIDD), in which plasma polymerization is used to immobilize Ag-NPs on a substrate which allows us to analyse nanoparticles upon exposure and retrieval in/from different complex environmental compartments. Plasma polymerization was used to immobilize the Ag-NPs on a solid substrate. Plasma polymerization is a technique which allows surfaces to be modified with a thin functional polymer layer. These functional films can be applied on any type of substrate material. In this study, nanoparticles were immobilised on plasma polymerised Kapton tape supported by a polycarbonate frame with an internal window, of variable size (1-12cm). The nIDDs were exposed to a range of environmental conditions including a freshwater lake and in a marina, freshwater and saltwater sediments, a sewer system in Adelaide and to the atmosphere in a number of cities in Australia, Asia, Europe and the US. Upon retrieval, the chemical speciation of Ag on the exposed devices was determined by X-ray Absorption Near Edge Structure (XANES). In technological and environmental compartments the chemical and physical conditions play a dominant role in determining Ag speciation. In most cases, complexation of Ag by reduced sulfur groups is the key transformation mechanism but variability exists within various compartments. This study demonstrates that nIDDs can be also used to explore NP transformation in highly dynamic and spatially heterogeneous environments.

### Adverse outcome pathway concept in research and risk assessment

359

#### Quantitative AOP Linking Aromatase Inhibition to Impaired Reproduction: A Case Study in Predictive Ecotoxicology

D.L. Villeneuve, U.S. EPA / Midcontinent Ecology Division; G.T. Ankley, U.S. EPA / National Health and Environmental Effects Research Laboratory; R.B. Conolly, U.S. EPA / Integrated Systems Toxicology Division; W. Cheng, US EPA; D.H. Miller, Midcontinent Ecology Division; M.L. Mayo; E.J. Perkins, US Army Engineer Research and Development Center / Environmental Laboratory; E.C. Randolph, U.S. EPA / Midcontinent Ecology Division; K.H. Watanabe, Oregon Health & Science University / Environmental and Biomolecular Systems  
The adverse outcome pathway (AOP) framework is intended to help support greater use of mechanistic toxicology data as a basis for risk assessment and/or regulatory decision-making. While there have been clear advances in the ability to rapidly generate mechanistically-oriented data for large libraries of chemicals using in vitro high throughput assays, questions remain about whether the AOP framework can be used to help translate those data into quantitative predictions of the probability or severity of an adverse outcome. This study couples together a series of computational models to yield a quantitative AOP (Q-AOP) construct capable of taking the in vitro relative potency of an aromatase inhibitor as an input and predicting potential effects on fish reproduction, as well as simulating the dose-response time-course behaviors at several key events. As a case study in predictive ecotoxicology, US EPA Toxcast results were used to select eight chemicals that were active in mammalian cell-based and cell-free bioassays designed to detect aromatase inhibition. At test concentrations ranging up to 130 µM, seven of the eight chemicals selected also inhibited fathead minnow ovarian aromatase activity in vitro. Simulations based on the Q-AOP construct predicted that continuous exposure to 2, 10, or 50 µg fadrozole-equivalents/L would lead to 20% to >99% reductions in population size over a 10 year period. However, two independent mechanistically-based models linking aromatase inhibition to

predicted plasma vitellogenin concentrations yielded markedly different dose-response time-course behaviors and subsequent population trajectories. These results suggest that model uncertainty could be reduced considerably through additional iterations of model testing and refinement. Nonetheless, the case study supports the feasibility of using computational representations of generalized biological response motifs in the form of a Q-AOP as a basis for translating mechanistic data generated via high throughput screening into meaningful predictions of ecotoxicologically-relevant outcomes. *The contents of this presentation neither constitute nor necessarily reflect US EPA policy.*

#### Chemoinformatics approaches for defining Molecular Initiating Events within an Adverse Outcome Pathway for Chronic Toxicity

S.J. Enoch; M.D. Nelms, F.P. Steinmetz, C.L. Mellor, A. Richarz, Liverpool John Moores University; J. Madden, Celsis Invitro Technologies; M. Cronin, Liverpool John Moores University

The Adverse Outcome Pathway (AOP) approach centres on identifying and understanding the key, testable, steps in a biological pathway that when perturbed leads to a toxicological response. It is envisaged that the identification of key events will allow for the development of intelligent testing strategies consisting of *in silico*, *in vitro* and *in chemico* methods. One of the most challenging endpoints for the AOP paradigm is chronic repeated dose toxicity, following exposure of humans or environmental species to a toxicant. Within the AOP approach, chemoinformatics methods enable knowledge concerning the Molecular Initiating Event (MIE) to be encoded as *in silico* profilers. These profilers enable chemicals to either be prioritised for further, non-animal, testing or grouped into categories allowing data-gaps to be filled via read across; this offers a potential route for non-animal safety assessment in a number of industries. This presentation will outline the development of two profilers for organ-toxicity where the MIE is either 1) the transport either, protons across the mitochondrial membrane, or electrons directly from complex I to complex IV in the respiratory chain or 2) the inhibition of the nuclear receptor family of proteins. Where MIEs are conserved across species this also presents an opportunity to predict toxicological effects in species for which empirical data are unlikely to be available. This work describes the development of *in silico* profilers, based on knowledge of the MIE that can be used to predict organ-level toxicity. Whilst the focus of this study relates to human health, the potential for extrapolation across species, using knowledge of the MIE, is also discussed.

#### Development of an adverse outcome pathway from bile salt export pump inhibition to cholestatic injury

M. Vinken, Vrije universiteit Brussel / Toxicology; B. Landesmann, European Commission DG Joint Research Centre; S. Vinken, Algemeen Stedelijk Ziekenhuis Aalst / Department of Endocrinology; H. Jaeschke, University of Kansas Medical Center / Department of Pharmacology Toxicology and Therapeutics; C. Willett, the Humane Society of the United States / Animal Research Issues; M. Whelan, European Commission DG Joint Research Centre / European Union Reference Laboratory for Alternatives to Animal Testing EURL ECVAM; V. Rogiers, Vrije universiteit Brussel / In Vitro Toxicology and DermatoCosmetology  
Adverse outcome pathways (AOPs) have been recently introduced in human risk assessment as pragmatic tools with multiple applications. As such, AOPs intend to provide a clear-cut mechanistic representation of pertinent toxicological effects. AOPs are typically composed of a molecular initiating event, a series of intermediate steps and key events, and an adverse outcome. In this study, an AOP framework is proposed for cholestasis triggered by drug-mediated inhibition of the bile salt export pump transporter protein. For this purpose, an in-depth survey of relevant scientific literature was carried out in order to identify intermediate steps and key events. The latter include bile accumulation, the induction of oxidative stress and inflammation, and the activation of specific nuclear receptors. Collectively, these mechanisms drive both a deteriorative cellular response, which underlies directly caused cholestatic injury, and an adaptive cellular response, which is aimed at counteracting cholestatic insults. AOP development was performed according to Organisation for Economic Co-operation and Development (OECD) guidance, including critical consideration of the Bradford Hill criteria for weight of evidence assessment and the OECD key questions for evaluating AOP confidence. The postulated AOP is expected to serve as the basis for the development of new *in vitro* tests and the characterization of novel biomarkers of drug-induced cholestasis.

The current approach to assessing adverse effects of chemicals in the environment is largely based on a battery of *in-vivo* study methods and a limited number of accepted *in-silico* approaches. For most substances the pool of data from which to predict ecosystem effects is limited and often only short term data are available. The EC Scientific Committee Consultation paper 'Addressing the New Challenges for Risk Assessment' (2012) highlights some of the main areas for improvement of current risk assessment approaches. The report also outlines the potential advantages and challenges of conducting effects assessments using data from lower hierarchical (biological) levels of organization, such as molecular, biochemical and histological responses, to infer impacts at the individual level. The adverse outcome pathway (AOP) framework provides a conceptual basis through which linkages can be explicitly assessed across biological levels of organization. There are substantial international efforts to develop and catalogue AOPs and develop implementation guidance for risk assessment. 'Omics approaches offer potential for use in environmental risk assessment when applied as part of a systems toxicology or integrative approach, and considered in the context of the AOP framework. For example, 'omics have the potential to provide mechanistic information about the effects of chemicals and to increase confidence in species extrapolation. These techniques have the real potential to i) provide insights as to the toxic mechanisms for both defining and, importantly, defined pathways via which adverse risks arise and to ii) help with targeted risk assessment. They also have longer term possibilities to (iii) be combined with mechanistic effect models that may (begin to) account for some of the complexity of populations, communities and ecosystems. A recent workshop drawing together experts from the academic, industry and regulatory authority communities discussed the role and highlighted the key challenges of employing 'omics' techniques as part of the AOP framework to support environmental risk assessment of chemicals.

### 363

#### **How do non-specific mechanisms of toxicity fit into the AOP framework? The example of narcosis.**

D. Knapen, University of Antwerp / Zebrafishlab Dept Veterinary Sciences; E. Stinckens, Zebrafishlab Veterinary Physiology and Biochemistry Department of Veterinary Sciences; S. Nørgaard Schmidt, Technical University of Denmark / Dept Environmental Engineering; W. Maho, University of Antwerp / Toxicological Centre Dept Pharmaceutical Sciences; P. Mayer, Technical University of Denmark / Department of Environmental Engineering; A. Covaci, University of Antwerp, Toxicological Center / Toxicological Centre; L. Vergauwen, University of Antwerp / Zebrafishlab Dept Veterinary Sciences

Adverse Outcome Pathway (AOP) development is currently being formalized around a set of internationally harmonized principles. While these principles can often be applied in a relatively straightforward manner in cases in which the sequence of key events (KEs) is fairly specific, defining and describing appropriate re-usable KEs can be particularly challenging when relatively non-specific toxicological mechanisms are involved. A well-known example of such a non-specific mechanism is membrane disruption through narcosis, which is commonly accepted to result from accumulation of lipophilic chemicals in membranes disrupting membrane integrity and function. It has been difficult to delineate a complete AOP for narcosis, resulting in insufficient understanding of the exact mechanisms involved to e.g. support robust read across groupings based on mechanism of action. We summarized the two main pathways that have been described for narcosis in a hypothesized AOP. The first outlines a generalized pathway leading to a loss of equilibrium and mortality at the organismal level through changes in cellular respiration and metabolic rate. The second focused on disruption of epithelium of primary and secondary gill lamellae resulting in pathologic alterations, ultimately causing hypoxia and respiratory failure. We applied a passive dosing method to expose zebrafish embryos up to 5 days to a linear dilution series of phenanthrene. We observed reduced survival (LC<sub>50</sub>: 310.0 µg/l), and reduced growth with increasing accumulated dose. We observed that the distance travelled was significantly reduced in all phenanthrene exposure concentrations. We found that while exposed larvae were able to reach high swim speeds (> 10 mm/s), they travelled less distance at these high speeds. We also found that impaired inflation of the posterior swim bladder chamber was the most important sublethal morphological effect after phenanthrene exposure. One could expect that the reduced swimming activity is caused by the failure to inflate the swim bladder. However, the effect of impaired swim bladder inflation on swimming activity was small relative to the narcosis effect. Currently, we are defining underlying key events leading to these adverse outcomes. We are currently

in the process of determining the distribution of narcotic compounds across different membrane types (cell membrane versus mitochondrial membrane), and of evaluating *in vitro* tools for the assessment of narcotic effects.

### 364

#### **Cause and effect: drug plasma concentrations drive the multi-level effects of synthetic glucocorticoids in fish**

L. Margiotta-Casaluci, Brunel University / Institute for the Environment; B. Huerta Buitrago, Catalan Institute for Water Research (ICRA) / Department of Water Quality; S. Kugathas, Brunel University / Institute for the Environment; S. Rodriguez-Mozaz, Institute for Water Research (ICRA) / Water Quality; D. Barcelo, IQAB-CSIC / Institute for Environmental Assessment and Water Research; S.F. Owen, AstraZeneca / Safety Health Environment; M. Rand-Weaver, Brunel University / College of Health and Life Sciences; J.P. Sumpter, Brunel University / Institute for the Environment

Synthetic glucocorticoids (GCs) have important clinical utility both as anti-inflammatory and immunosuppressive agents. These compounds act by modulating the glucocorticoid receptors (GR), but can also interact with other molecular targets (off-targets), including the androgen receptor (AR). Recent studies reported GR activity in wastewater effluents and surface waters, but this activity could not be explained by the chemical analysis of known glucocorticoids. Considering the key role of GR in physiological processes, understanding the consequences of the disruption of GR signalling in non-target species is a priority. Despite the likely source, GR activity in the environment has not been linked to any known pharmaceutical. In this context, the characterization of the pharmacological and toxicological effects of model GCs in fish could provide an important knowledge-platform to predict the potential effects of GR activity detected in the environment. Here we provide an integrated assessment of the multi-scale effects of beclomethasone dipropionate (BDP) in the teleost fathead minnow (*Pimehales promelas*) anchored to drug plasma concentrations. The endpoint selection was driven by the Read-Across approach and by the cross-species extrapolation of clinical and pre-clinical data. The expression of a set of five genes was linked to relevant endpoints at higher level of biological organization. In particular, the gene expression of GR, AR, phosphoenolpyruvate carboxykinase (PEPCK), interleukin-6 (IL6) and tumor necrosis factor alpha (TNF-α) was linked to the expression of secondary sexual characteristics, levels of plasma glucose, and effects on white blood cells population. The latter set of endpoints corresponds to typical adverse or therapeutic effects occurring in humans: e.g. skin androgenisation, hyperglycemia, and immunosuppression. The effects were characterized by performing two independent 21-day exposure experiments in flow-through conditions during which adult fish were exposed respectively to 10, 100 and 1000 ng/L (Experiment 1) and 10 and 1000 ng/L (Experiment 2). The two experiments were designed in order to achieve the same drug peak blood concentration (C<sub>max</sub>) but different drug-concentration-time profiles (Area Under the Curve, AUCs), which reflect the actual body exposure to the drug. We will discuss the results of these studies and the implications for both Environmental Risk Assessment of GCs and Adverse Outcome Pathway concept.

#### **Midpoint or single score for decision making? (II)**

### 365

#### **A Normalization Approach for Simplified Ecodesign Tools in the Food Sector**

U. Schenker, Nestle Research Center; N. Espinoza-Orias, Nestec Ltd. / School of Chemical Engineering and Analytical Science

Nestlé, the world's leading Nutrition, Health, and Wellness company has, in the past six years, used simplified eco-design tools to evaluate the environmental impacts of over 15'000 packaging design alternatives. Today, a new eco-design tool called EcodEX has been developed and implemented which extends the assessment process to also evaluate food products. Users of the tools are typically packaging or food scientists with limited background in LCA and environmental sciences. All assessments cover between five and eight environmental impact indicators, typically at midpoint level. Decision making is a challenge for the tool users, because it is difficult for them to judge which indicators "matter most" for any given project. Several approaches have been tested to overcome this: using "intuitively" understandable equivalency units for LCA indicators (such as "number of showers" for liters of water, or "km driven by car" for kg CO<sub>2</sub>eq), and providing qualitative rules of thumb (such as: GHG emissions matter for products with dairy ingredients, water use matters for products with use of irrigation in agriculture). Neither approach was fully satisfactory. A new normalization approach has been recently implemented which is inspired by guidance on nutrition Recommended Daily Intakes (RDI). The approach normalizes the existing environmental indicators with the average daily impacts of one person in Europe. The resulting number, which is a percentage, is easy understandable by packaging & food scientists, as it is closely related to the Recommended Daily Intake in nutrition. This approach easily allows the identification of those indicators that matter most for any given product system. For instance GHG emissions were shown to play an important role in dairy products (related to enteric fermentation in cattle), as was water consumption for coffee-related products (given that irrigation is frequently used in green coffee cultivation). While the different normalized indicator scores are not summed together, the fact that they are displayed next to

each other implies that equal weighting factors are used for each of the indicators, without aggregating to a single score. The proposed approach is much more transparent than single score indicators because it can still easily be seen which design alternative performs better with regards to the different indicators.

366

**The PROSUITE (aggregation) methodology for sustainability assessment: lessons learnt from the biorefinery case study**

S. De Meester, Ghent University / Department of Sustainable Organic Chemistry and Technology; M.K. Patel, University of Geneva / UNIGE; J. Dewulf, EC JRC - IES / Sustainability Assessment unit

In the FP7 project PROSUITE, Prospective Sustainability Assessment of Technologies, an integrated method was developed that quantifies impact on the three dimensions of sustainability: People, Planet, Profit including both micro and macro scale effects. The final PROSUITE framework consists of a selection of 40 midpoint indicators of relevant social, economic and environmental aspects and groups this into 5 endpoints, namely: impact on social well being, prosperity, exhaustible resources, natural environment and human health. Background data has very different origins; e.g. ecoinvent, input output tables, ILO statistics, etc. Aggregation, required to reduce complexity and allow decision making is thus a big challenge in such an assessment method. Ideally, the different midpoints could be linked by a scientifically sound cause-effect chain, however, whereas this endpoint modelling is already relatively uncertain in quantification of impact on natural environment this becomes much more complex when trying to include other dimensions and scales. To end up with an integrated assessment a combination was used between endpoint modelling and different options taken from multi-criteria analysis such as the weighted sum and outranking methods (Condorcet). The aim of this work is to give feedback on the experience within the biorefinery case study and to summarize in a concrete example how PROSUITE can answer the question if bioenergy is more sustainable than traditional energy production. The link is made between the final result, the used data sources, used units, the models between midpoints and endpoints and subsequently the aggregation to a single sustainability index. Finally conclusions are formulated on how such a complex assessment methodology should be interpreted and communicated.

367

**What if we would use endpoint results for estimating midpoint weighting factors?**

T. Ponsioen, PRe Consultants / Consultancy; M. Goedkoop, PRe Consultants  
There is often a preference for communicating life cycle assessment results at midpoint level, because endpoint methods are generally considered as highly uncertain. However, the importance of the impact on the different midpoint categories is difficult to determine without considering the information in endpoint methods. While the uncertainty of endpoint results is high, their scientific approach could provide a more solid basis for midpoint weighting factors than value judgment. This paper shows how to estimate midpoint weighting factors based on the endpoint single score results of the same impact assessment method framework and present the results. The ReCiPe method was chosen because it contains a large set of midpoint and endpoint categories. Water scarcity categories were added from a compatible method. The calculated midpoint weighting factors based on endpoint scores show a similar importance of climate change compared to the stakeholder weighting. All other factors are radically different. While midpoint weighing schemes based on panels usually have a range of factors lower than a factor 15, we now see ratios of more than 1000. There are two ways to look at this: the endpoint factors are so uncertain that they must be wrong or the way a panel assesses midpoint weighting is flawed. The problem in midpoint panel procedures are well understood in social science. There are a number of issues that are often overlooked when panels are used: a) there are too many issues at midpoint, b) the way the questionnaire is formatted creates biases, c) people have different experiences (observed, perceived or predicted), and d) people relate to what they understand (environmental issues are difficult to understand). It must be noted that stakeholder weighting is used at endpoint, but this involves fewer issues and sensitivity analysis shows the results are robust. Using midpoints as environmental impact indicators are useful for benchmarking and monitoring. However, determining the relevant impact categories is challenging when working with midpoints. When stakeholders are asked how to assign weighting factors on midpoint categories, the results will deviate extremely from those obtained with endpoint methods. Stakeholder weighting at midpoint is per definition unreliable and should be avoided. Weighting factors based on endpoints will provide decision makers with much more realistic information on which categories are important for the studied product.

368

**LCA for decision support**

F. Dinkel, T. Kägi, Carbotech AG

Weighting the different LCIA indicators to form a single score indicator is a particularly necessary step for different purposes e.g. to evaluate the relevant impact categories considered in a LCA or in a comparison of different options, in order to base a decision not only on one or few indicators but to take all different indicators into account. This is required when the various indicators do not lead to the same conclusions. On the other hand it is well known that weighting is based on value choices and not on natural science. That is why according to ISO weighting

shall not be used for comparative assertions disclosed to the public. So what should be done if a recommendation has to be given to customers e.g. from authorities? What will be the consequences if decisions are strictly based on ISO? The big advantage of the different midpoints is that the LCA practitioner gets an insight into the different impacts and can also take the local situation into account for the conclusions. So he has to substantiate the conclusions. This is why, the relevance of the different indicators is crucial and single score methods based on consensus and not only on personal opinions are not only helpful but necessary. As the analysis of the weighting methods of the last thirty years has shown, the weighting corresponds to the actual knowledge, political topicality and social awareness. In order to reach a sound decision, different single score methods should be used to conduct sensitivity analysis, which allows assessing the consequences on the LCIA results due to different value-choices of the weighting methods. Single score indicators do not tell the truth but can be very helpful when it comes to decision support and to communicate an outcome. However it is crucial not to use only one single method for the conclusions and that the values behind as well as the coverage is known and adequate to the goal and scope of the study. So we suggest completing the requirement in the norm as follows "More than one single score method shall be used for comparative assertions disclosed to the public and the weighting has to be discussed."

**Mixture toxicity assessment of biocides -from theory to practice: state of play and analyses for 30 products**

A. Kehler, Federal Environment Agency / IV Biocides; A. Coors, ECT Oekotoxikologie GmbH; F. Sacher, DVGW-Technologiezentrum Wasser; B. Schwarz-Schulz, Federal Environment Agency (Umweltbundesamt, UBA)  
Biocidal products are typically mixtures of one or more active substances as well as further ingredients. For the authorisation of biocidal products an extensive environmental risk assessment (ERA) is required in accordance with the biocidal products regulation (BPR, 528/2012), i.e. not only every active substance in the product has to be subject of an environmental risk assessment, but also substances of concern, e.g., substances leading to classification of the product or having PBT, endocrine or CMR properties, have to be evaluated separately. In addition the combined toxicity of these ingredients needs to be taken into account according to the legal text. From 2011 until 2013 a proposal for the (environmental) risk assessment of the mixture toxicity of biocidal products was developed under the lead of Germany which was agreed between member states and industry at technical level and is already published at ECHA's website as transitional guidance. This proposal includes several screening steps, i.e. estimation of the potential exposure of environment, screen for synergistic effects and identification of relevant substances as well as a tiered mixture toxicity assessment scheme. Thereby, an initial assessment is already possible with a very limited set of data, using an adequately precautionary approach. In case no indications for a reason for concern are detected, no further testing or data evaluation is required. If there are potential reasons for concern, additional data can be supplied in order to allow a more detailed assessment. In an ongoing research project 30 biocidal products from 3 different product types were analysed in detail for their composition regarding active substances and substances of concern as well as further ingredients which might be relevant for risk assessment according to mixture toxicity predictions and GHS legislation. The biocidal products belonged to the product type wood preservatives (PT 08), rodenticides (PT 14), and insecticides, acaricides and products to control other arthropods (PT 18). In the presentation the results of the analyses will be presented in context of the transitional guidance document for the mixture toxicity assessment of biocidal products especially regarding the definition of relevant substances, i.e. product components that should be included in a mixture assessment.

372

**Estimating the environmental risk of the societal stock of additives in plastics by a chemical footprint approach**

T.V. Rydberg, J. Lexén, IVL Swedish Environmental Research Institute; L. Dahlgren; A.P. Cousins, M. Rahmberg, IVL Swedish Environmental Research Institute; H. Andersson, IVL Swedish Environmental Research Institute Ltd / Department of Chemical and Biological Engineering; J.E. Grönholdt Palm, Department of Studies in Environmental Science; U. Sahlin, Linnaeus University, School of Natural Sciences

Environmental risk posed by additives in products in the technosphere in general and in consumer products in particular, is an important issue that has been, so far, investigated to a relatively limited extent. Previous estimates of the national stock and emissions are available on national scale [1,2,3] but the challenge has remained to understand how important or significant these stocks and emissions are from a risk perspective. The research presented here approaches the challenge by assigning risk characterisation scores to the additives and comparing the outcome with corresponding risk characterisation for biocides. We used the previous estimates on stock and emissions of plastic additives. Data for use of biocides were extracted from the Swedish Chemicals Agency. The risk characterisation was carried out by applying USEtox characterisation factors (CF). The amount of each substance, has been multiplied with its corresponding CF from USEtox. These substance specific risk scores were then added to the overall risk score. It is clear that there are many uncertainties in the calculations. For example the emission calculations in the overall society example seem unreasonably high, in the order of 2 % annually of the total stock. In other work applying an advanced emission model to a limited sample of products, the emission rate is in the order of 0.02 % annually. This indicates that the overall society-wide emissions could be in the order of 500 tons rather than 47000 tons. For the risk scores, the uncertainty is even bigger, as the uncertainty of the CFs themselves come into play, as well as the incomplete availability of CFs. The total risk score for the National total use of biocides is 9.3E+09 CTU. This is to be compared with the risk scores as calculated for the additives, which is 1.3E+12 CTU for the total stock of additives and 3E+10 CTU for the emissions, or possible a factor 100 lower if assuming a similar overestimation as for emissions. The results are very sensitive to the identified uncertainties, and also to lack of CFs for possibly important substances, both among the additives and the biocides.

### 373

#### **Environmental risk assessment of chemical mixtures: is a specific mixture assessment factor (MAF) the right way forward to improve current regulatory approaches?**

T. Backhaus, University of Gothenburg / Department of Biological and Environmental Sciences; M. Gustavsson, Department of Biological and Environmental Sciences; A. Hartmanns, University of Gothenburg / Department of Biological and Environmental Sciences; M. Faust, Faust & Backhaus Environmental Consulting; M. Klar, H. Sundberg, S. Gabring, G. Ericson, S. Flodström, Swedish Chemicals Agency

Current regulatory frameworks risk-assess chemicals one at a time. It has been repeatedly pointed out that this approach is not sufficiently protective, as humans as well as environmental organisms are *de facto* exposed to complex chemical mixtures. It has been previously discussed to account for the increased toxicity of such cocktails during regulatory risk assessment by implementing a specific additional Mixture Assessment Factor (MAF) of “n”, the number of components in the mixture. It can be proven that such a MAF is sufficiently protective under the assumptions that (i) the mixture behaves according to concentration addition, and (ii) that none of the components is present at a concentration that poses an individual risk. However, such a MAF might become overly conservative in situations in which only a few compounds dominate the expected toxicity of a mixture and it (obviously) requires to provide an estimate of the actual number of components in the mixture. These assumptions and limitations pose the question whether and in which situations a default MAF of “n” might be a suitable approach to account for mixture toxicities in regulatory risk assessment, or whether there are alternative approaches available – which will be discussed in the presentation. In order to identify the appropriate size of a MAF for environmentally realistic mixtures, we selected specific mixture scenarios from the open literature and used them as basis for simulation studies. The impact of specific toxic unit distributions, modes and mechanisms of action of the mixture components, (eco)toxicological endpoints and exposure scenarios will be discussed.

### 374

#### **Mixture Toxicity Prediction via a Quantitative Toxicogenomic-based Approach**

N. Gou, Northeastern University / Civil and Environmental Engineering; A. Gu, Department of Civil & Env Engineering / Department of Civil Env Engineering Biotechnology Initiative Program

The mixture toxicity has been a major concern and longstanding research topic in water toxicity assessment. Recent years, toxicogenomic approaches provide tools to improve our understanding and predictability of the mixture toxicity. However, current evidence to support the published mixture assessments from toxicogenomic studies is as yet mainly observational and needs further improvement. Few exposure situations were considered, and quantitative prediction of the combined effects is lacking. In this study, we demonstrated the application of a toxicogenomic-based approach for investigating the combined effects of various binary mixtures with a range from environmental relevant concentration to the benchmark level. Five binary mixtures were investigated at various concentrations with a fixed ratio (w/w). Cellular level responses (indicated by our quantitative omic- index TELI) evoked by most of the binary mixtures exposure exhibited clear dose-response patterns as single chemicals did. The TELI values were studied using the 4-parameter logistic regression model for further analysis. To quantitatively analyze the combined effects of mixtures, two additive models were applied – concentration addition (CA) and independent action (IA). Parallel dose-response

curves were found among As, Cr and the mixture, which indicate similar mode of action (MOA), and the experimental observed mixture toxicity fit well to both CA and IA model predication ( $r^2 > 0.8$ ). For mixture of NDMA - atrazine, mitomycin – erythromycin, experimental observed toxicity fit better with IA model which may indicate dissimilar MOA. Significantly higher experimental toxicity than both model predications was found by the mixture of H<sub>2</sub>O<sub>2</sub>-sucralose indicating possible synergistic effect. And significantly lower experimental toxicity than both model predications was found by mitomycin C-sucralose indicating possible antagonistic effect. Furthermore, for the last two mixtures, the combined effects seem to be dose-dependent. Our results not only illustrated a rapid, sensitive, and informative approach for mixture toxicity studies, but also for the first time demonstrated the possibility to explicitly predict the combined effects at the molecular level (when additive effect is present. Although most of the mixture exhibited additive effect in our results, further investigation is required for better understanding of the factors that influence the combined effects.

### 375

#### **Azoles from Different Regulatory Frameworks: Combined Assessment with Regard to Wastewater Effluents**

A. Coors, ECT Oekotoxicologie GmbH; F. Sacher, DVGW-Technologiezentrum Wasser; P. Schwartz, Federal Environment Agency Germany; C. Polleichtner, Ecotoxicological Laboratory; U. Kühnen, Federal Environment Agency Germany; W. Drost, Federal Environment Agency (UBA) / Chemicals; D. Gildemeister, Umweltbundesamt Federal Agency of Environment / IV Pharmaceuticals

While the environmental risk assessment of human pharmaceuticals, biocides, plant protection products, cosmetics, and industrial chemicals is regulated in different legal frameworks in the European Union, these substances may be released together to surface waters via wastewater treatment plants. Hence, the consideration of the potential combined toxicity of these substances and the resulting environmental risks may need to be evaluated across different regulatory frameworks. Azoles were selected suitable example for a combined environmental risk assessment across regulatory boundaries based on the concept of concentration addition as they share the fungicidal mode-of-action and are used as pharmaceuticals, as plant protection products, as biocides, and in products regulated under REACH. The present study investigated the individual and combined effects of three azoles in the absence and the presence of diluted wastewater effluent to evaluate if conclusions drawn from testing artificial mixtures in the laboratory can be transferred to real-world mixtures. The observed toxicity of equipotent mixtures prepared in test medium deviated from the predicted toxicity by less than factor 5. Although there was a trend rather of overestimation of combined toxicity than underestimation, these results generally support the applicability of the concept of concentration addition for mixtures of azoles and also for sublethal endpoints. Results for the azole mixture tested with diluted wastewater effluent as background are pending, but will be ready for presentation at the Barcelona meeting.

#### **Transfer of emerging pollutants from Spanish biosolids used as agricultural soil amendments. Results of CECAREA project**

A. de la Torre, Environmental; I. Navarro, P. Sanz, CIEMAT; M. Porcel, F. Pro, G. Carbonel, INIA; M. Martínez, CIEMAT

The use of the organic fraction of sewage sludge and municipal solid waste compost (MSW) as agricultural amendment, offering benefits and acceptable risks to both soil and plants is one of the best outtings environmentally sustainable waste. Nevertheless, it is important to emphasize that contaminants like heavy metals, pathogenic microorganisms and much of the organic pollution ends up in wastewater and in the MSW compost. The pathogens can be removed by various treatments, but there are some organic compounds that do not break down easily during wastewater treatment and / or MSW composting, and tend to accumulate in biosolids. Consequently, if they are used for agricultural purposes, could originate problems due to toxicity, bioaccumulation and transfer through the food chain. Responding to this concern, scientific community has made important efforts to characterize waste, by detecting some emerging pollutants (halogenated flame retardants and perfluorinated chemicals) in this kind of biosolids. Nonetheless, there is still a lack of knowledge regarding their fate, transfer or potential bioaccumulation after soil amendment. For this reason, Spanish Ministry of Economy and Competitiveness funded the “CECAREA” project to evaluate environmental consequences of utilizing biosolids as agricultural soil amendments and determine the fate, potential for transfer and accumulation and risks related to polybrominated diphenyl ethers (PBDEs), decabromodiphenyl ethane (DBDPE), decloranes and perfluorinated compounds (PFCs). This work aims to include and summarize the different experiments performed under the frame of CECAREA project from 2011 to 2013. Results provide evidence of transfer of PBDEs, DP and PFCs from biosolid amended soils to terrestrial ecosystems. Risk characterization ratios (RCR) for the chemicals considered were below 1, which means that risk is adequately controlled. The present work has been funded by the Spanish project CTM2010-19779-C02-01/02.

### The sorption mechanism of sulfonamide antibiotics on humin and its subfractions extracted from peat soil

X. Guo, Peking University / College of urban and environmental science; X. Wang, Peking University; S. Tao, Peking University / College of Environmental Sciences; B. XING, Department of Plant, Soil and Insect Sciences / University of Massachusetts

Humin (HM) is known as the strongly associated organo-mineral composite formed by natural organic matter in soils. Until now, the role of humic acid and fulvic acid as sorbents for organic contaminants has been extensively studied. In contrast, the research concerning on the sorption of the HM fraction is far from enough, even though it typically represents more than 50% of the organic carbon in soil. The sulfonamide antibiotics given to livestock are poorly metabolized and absorbed, thus a large fraction is released into the soil environment, causing the proliferation of antimicrobial-resistant pathogens and further affecting humans. Their sorption to soil organic matters (SOMs) is a critical process controlling their transport, bioavailability, and reactivity in soil. Therefore, to probe sorption mechanism between sulfonamide antibiotics and humin components is of great importance. In this study, two kinds of high-use sulfonamide antimicrobial, sulfamethazine (SMT) and sulfamethoxazole (SMX) were chosen as subject compounds. Four procedures were used to remove ash, carbohydrate, lipid and lignin component from original humin sample to investigate the impact of each component on sorption more clearly and confidently. After e-ashing treatment, both surface and bulk polarity of humin samples decreased, leading to the increase of their sorption for both SMT and SMX. The abundant polar groups on the surface were removed with mineral components, thus the more hydrophobic organic groups that were previous masked by minerals became available to sorbates. Those hydrophobic organic moieties could interact with sorbates via van der Waals force, and also form pi-pi bond with the benzene ring in the molecule of SMT and SMX, thus enhancing the sorption intensity. Similarly, the removal of lipid and lignin components enhanced the sorption for both SMT and SMX as well. However the mechanisms of sorption increment were different from the de-ashing process. These organic components may block high affinity sorption sites in the interior part of HM. The condensed organo-mineral complex components inside HM became available to the sorbates after the removal of lipid and lignin components. The sorption nonlinearity for SMT and SMX also enhanced after each treatment. Those components in humin removed by chemical procedure were comparatively homogeneous, while leaving those highly heterogeneous components in the residue material, resulting in high sorption nonlinearity.

### 378

#### Supporting microbial activities by using electrodes as electron acceptors: strategies to biomineralize 14C herbicides in soils

J. Rodrigo, Helmholtz centre for environmental research - UFZ / Soil Department; A. Dominguez, Universidad de Alcalá; U. Dörfner, R. Schroll, Helmholtz Zentrum München / Institute of Soil Ecology; A. Esteve-Núñez, University of Alcalá Bioelectrochemical systems (BES) show tremendous potential for utilization in environmental application. Sedimentary Microbial Fuel Cells (smFC), one of this BES, use electrodes to supply the electron acceptors required for contaminant biodegradation in contaminated soils, where the organic pollutants play the fuel role for microbial electrogenic communities. We propose to name this kind of bioelectrochemical devices as Microbial Remediating Cell (MRC). Polycyclic aromatic hydrocarbons as dibenzothiophene (DBT), and chloroaromatic compounds as the herbicides diuron and atrazine were shown to be efficiently biodegraded under electrogenic conditions in our laboratory, showing rates 10-times faster by using electrogenic approaches in contrast with the natural biodegradation. Here, we will review the results of our recent investigation on the use of MRC for in situ bioremediation of 14C herbicides. Radiolabelled compounds allow us to control the pollutant fate and establish a strict mass balance of 14C. For monitoring these processes, we have designed a special set up, adapting the MRC to a closed laboratory system, being possible to maintain total control of the overall behavior of the pollutant and to use chronovoltammetry and chronoamperometry for measuring electrons released from the pollutant microbial oxidation to the anode. The effective bioremediation task was confirmed by measuring the 14C radioactivity, followed by soil extraction and HPLC-radio detector analysis to identify 14C-metabolites. At last, the residual radioactivity bound to the soil is determined by combustion processes, leaving defined all terms for the mass balance of 14C. The results support the concept of electrogenesis-stimulated bioremediation, being intensely increased the mineralization of 14C IPU under electrogenic conditions (MERCs with anode at 0.6 V vs NHE) with the parallel change in the metabolite-pattern. Concretely, the intrinsic soil capability to mineralize IPU under flooded conditions was enhanced by ca. 40-fold, reaching high mineralization rates even at the initial stage of the experiments.

### 379

#### Phytotreatment of polychlorinated biphenyls contaminated soil by *Chromolaena odorata* (L) King and Robinson

R.O. ANYASI, University of South Africa / Environmental Sciences; H.I. Atagana, University of South Africa / GRADUATE STUDIES

In this study, phytoextraction ability of a weed on Aroclor 1254 was studied under greenhouse conditions. *Chromolaena odorata* plants were transplanted into soil

containing 100, 200, and 500 ppm of Aroclor in 1L pots. The experiments were watered daily at 70 % moisture field capacity. Parameters such as fully expanded leaves per plant, shoot length, leaf chlorophyll content as well as root length at harvest were measured. PCB was not phytotoxic to *C. odorata* growth but plants in the 500 ppm treatment only showed diminished growth at the sixth week. Percentage increases in height of plant were 45.9, 39.4 and 40.0 for 100, 200 and 500 ppm treatments respectively. Such decreases were observed in the leaf numbers, root length and leaf chlorophyll concentration. The control sample showed 48.3 % increase in plant height which was not significant from the treated samples, an indication that *C. odorata* could survive such PCB concentration and could be used to remediate contaminated soil. Mean total PCB absorbed by *C. odorata* plant was between 6.40 and 64.60 ppm per kilogram of soil, leading to percentage PCB absorption of 0.03 and 17.03 % per kilogram of contaminated soil. PCBs were found mostly in the root tissues of the plants, and the Bioaccumulation factor were between 0.006-0.38. Total PCB absorbed by the plant increases as the concentration of the compound is increased. With these high BAF ensured, *C. odorata* could serve as a promising candidate plant in phytoextraction of PCB from a PCB-contaminated soil. **Keyword:** Phytoremediation, Bioremediation, Soil restoration, Polychlorinated biphenyls (PCB), Biological treatment, Aroclor.

### 380

#### Climate change effects on PAH photodegradation in Mediterranean soils

M. Marques, Rovira i Virgili University / Chemical Engineering; M. Mari, Rovira i Virgili University / Chemical Engineering; J. Sierra, Universitat Rovira i Virgili / Soil Science Unit; M. Schuhmacher, Rovira i Virgili University / Chemical Engineering; J.L. Domingo, Universitat Rovira i Virgili / Laboratory of Toxicology and Environmental Health; M. Nadal, University Rovira i Virgili / Laboratory of Toxicology and Environmental Health

The potential of climate change to alter the environmental distribution and biological effects of chemical toxicants, such as persistent organic pollutants (POPs) and other semi-volatile organic compounds, have been studied during the last years. Polycyclic aromatic hydrocarbons (PAHs) are a family of widespread environmental pollutants, whose chemical structure is based on two or more fused benzene rings. PAHs are released from natural and anthropogenic combustion processes. Environmental fate and transport of PAHs is highly influenced by temperature and solar radiation. Thus, PAHs are likely to be impacted by changes in temperature and radiation related to climate change. This study was aimed at estimating the loss rate of PAHs by means of photodegradation in two typical Mediterranean soils, after comparing two climate scenarios. Soil samples were taken from the A horizon of two common Mediterranean soils located in remote areas. Arenosol soil samples corresponded to Haplic Arenosol, an acidic and coarse-textured soil with granitic origin. In turn, Regosol soil samples belonged to Calcic Regosol, which is formed of sedimentary materials and fine-textured soil. Five grams of cleaned soil were deployed in uncovered glass Petri dishes. Every sample was spiked with 125 µL of a stock solution containing 16 US EPA priority PAHs at a concentration of 100 µg/mL and exposed to different climate conditions in a climate chamber. In order to assess any potential changes in PAH concentrations over time, soil samples were daily removed from the climate chamber the following days: 1, 2, 3, 4, 5, 6, 7, 14 and 28. Dark controls were also performed to assess slow sorption processes. The results showed that PAHs behaved differently according to their molecular weight, temperature, radiation and soil texture. A decreasing trend of PAH concentrations in both soils in samples exposed to daylight was observed, being the loss rate higher in the climate change scenario. Low molecular weight PAHs are more influenced by volatilization and sorption, while photodegradation is more evident for medium and high molecular weight PAHs. Photocatalysis may enhance photodegradation processes in the fine-textured soil, possibly due to the presence of iron, silicon, manganese oxides as well as humic acids. Future studies will be focused on the potential formation of metabolites in the PAH photodegradation process, since some of them could be even more toxic than their parental compounds

### 381

#### Decomposition of Perfluorinated Alkyl Acids in Enzyme-catalyzed Oxidative Humification Reactions

Q. Huang, Q. Luo, University of Georgia / Department of Crop and Soil Sciences Perfluorinated alkyl acids (PFAAs) have drawn increasing concern due to their global distribution, extreme persistency and environmental toxicity. The unique molecular structure of PFAAs make them extremely resistant to degradation, and thus it still remains a significant challenge to remediate soil or waters contaminated by PFAAs with environmentally friendly approaches. We have conducted a series of experiments to examine the degradation of PFAAs in enzyme-catalyzed oxidative humification reactions (ECOHR) in both aqueous phase and soil slurries. The experiments with aqueous solutions were conducted using laccase as a model humification enzyme, 1-hydroxybenzotriazole (HBT) as a model mediator, and perfluorooctanoic acid (PFOA) and perfluorooctane sulfonate (PFOS) as model target chemicals. We have also conducted experiments in soil slurries with laccase as the enzyme and soybean mill added to supplement natural mediators. The results of our experiments demonstrated that PFAAs can be decomposed in ECOHR under environmentally relevant conditions in both aqueous phase and soil slurries. The findings suggest that ECOHR may provide a novel scheme for in situ remediation of sites contaminated by PFAAs.

## Towards realistic and landscape based prospective ecological risk assessments: mapping variability and diversity

### Landscape based ecological risk assessment, available methods and future outlook (science and fiction)

F. Streissl, EFSA / Pesticides Unit; M. Arena, EFSA - European Food Safety Authority / Pesticides; D. Auteri, Auteri / Pesticides Unit; M. Egsmose, EFSA; A. Ippolito, EFSA - European Food Safety Authority / Institute for Environment and Sustainability IES; R. Sharp, EFSA - European Food Safety Authority / Pesticides Unit; C. Szentes, Pesticides Unit; J.V. Tarazona, European Food Safety Authority / Pesticides Unit

The presentation gives an overview on the advantages (and challenges) of moving from field based to landscape based risk assessments and spatial mapping of risk for pesticides. The potential use in risk assessment and risk management is highlighted. Important points for a spatially explicit risk assessment and risk mapping for the different regions in Europe are for example: the definition of specific protection goals for the landscape level and associated trigger values and risk assessment schemes. Furthermore, detailed maps (geo-referenced data) with a high resolution which include all important landscape elements and maps of distribution of species. Some of the data and tools are already available but others still need to be developed. Examples from recent EFSA opinions and guidance show how landscape based pesticide risk assessments could be developed in future.

### Harmonizing the Harmonized Test Guidelines: Fish Developmental Biology Terminology and Animal Testing Implications

S.E. Belanger, The Procter & Gamble Company / Environmental Stewardship and Sustainability Organization; T. Braunbeck, University of Heidelberg / Centre for Organismal Studies; M.R. Embry, ILSI Health & Environmental Sciences Institute (HE); B. Farr, ILSI Health and Environmental Sciences Institute (HESI); M. Halder, European Commission Joint Research Centre / DG Joint Research Centre IHCP EURL ECVAM; M. Lampi, ExxonMobil Biomedical Sciences, Inc.; J.M. Rawlings, The Procter & Gamble Company / Environmental Stewardship and Sustainability

A detailed review of current OECD fish test guidelines covering acute and chronic toxicity, bioaccumulation and endocrine disruption endpoints was conducted to assess variations in life stage terminology and life history descriptions. The goal of the review was to develop recommendations for harmonization and improvements to facilitate transparency in terminology. This will assist how guidelines are intended to be used in an integrated fish testing framework as previously discussed in OECD. Harmonization of terminology and appreciation for life history descriptions impact interpretations of fish tests in regards to animal welfare (what stages are or are not protected, how to decide when protection occurs, etc.) and can

also assist in emerging discussions regarding adverse outcome pathways. Approximately 3 dozen life stage terms (embryo, eleutheroembryo, larva, fingerling, etc.) were catalogued along with the context in which they were used. Terms were compared against standard definitions of life stages as given in the fish developmental biology, systematics, and ontogeny literature. Terms were grouped into a dozen well-defined life stage indicators and their frequency of use was mapped. Egg and embryo (equivalent terms) constituted roughly 25% of all life stage indicators. Sac-fry and sac-fry stage, a more ambiguous stage, constituted 10% of the terms used. Proposed alterations of terminology in some contexts were identified in order to facilitate cross-talk between various tests. In addition, research needs to provide quantification of some life stages (e.g., in terms of hours post-fertilization or days post-hatch) were developed. This latter aspect is possible due to the relatively standardized nature of tests in terms of species, test temperatures, and general water quality which influence developmental rates. The research needs include: (1) clear delineation of toxicologically relevant developmental stages should be known for all frequently tested species (today this is limited to only a few); (2) harmonization of endpoints relevant for each stage and test such that tests can continue to inform each other; (3) agreement on life stages and reduction in the mixing of technically informative terms (such as embryo, eleutheroembryo and larva) and lay terms (such as sub-adult and fingerling). This may require further research to define their meaning across systematically (i.e., taxonomy) diverse test species and life histories.

389

### When can a chronic fish test be waived? -A data analysis of species sensitivity

W. Drost, Federal Environment Agency (UBA) / Chemicals; M. May, Fraunhofer ITEM / Chemical Risk Assessment; S. Germer, German Federal Environment Agency; T. Juffernholz, German Federal Environment Agency (UBA) / Biological and Chemical Safety; F. Kassner, Federal Environment Agency UBA; S. Hahn, Fraunhofer ITEM / Chemical Risk Assessment

Based on the animal welfare concept and to avoid animal experiments (Art. 13, Art. 25), the REACH Regulation provides several options for waiving the chronic fish toxicity test. For the decision on the need of ecotoxicological tests on animals ECHA guideline R7b and R10 are applied. In particular guideline R7b provides guidance for the assessment of ecotoxicological endpoints and includes an integrated testing strategy (ITS). It is the aim of the ITS to avoid unnecessary vertebrate tests while being sufficiently protective. Based on a data analysis it was the aim to investigate the currently proposed hazard evaluation according to the ITS on the basis of already existing toxicity tests. The dataset used for analysis is based on data from the OECD eChemPortal and from the Information System Chemical Safety database (ICS) of the German Federal Environmental Agency. Based on the finding that the sensitivity in chronic testing is associated with sensitivity in acute testing a classification scheme for acute sensitivity comparison is proposed to contribute to the ITS. The data analysis suggests to adapt the current ITS as implemented in the corresponding guidance documents by reducing the sensitivity factor from 10 to 5. The physicochemical properties water solubility and the octanol-water partitioning have a supporting character if fish were 2x to 5x more sensitive than Daphnia in the acute tests but do not seem to be good indicators for the requirement of long term or vertebrate tests in general.

390

### Ecotoxicological Threshold of Concern (eco-TTC): Development of an approach to assist in environmental hazard assessment

M.R. Embry, ILSI Health & Environmental Sciences Institute (HE); S.E. Belanger, The Procter & Gamble Company / Central Product Safety Dept; H. Sanderson, Aarhus University / Environmental Science; D. De Zwart, RIVM / Centre for Sustainability Environment and Health; B. Farr, ILSI Health and Environmental Sciences Institute (HESI); M. Halder, European Commission Joint Research Centre / DG Joint Research Centre IHCP EURL ECVAM; R.M. Sternberg, U.S. EPA / Environmental Fate and Effects Division; P.W. Wilson, Sanofi U.S., Inc. / Health Safety and Environment

The Threshold of Toxicological Concern (TTC) concept is well established for assessing human safety of indirect food additives and has been reapplied for a variety of endpoints including carcinogenicity, teratogenicity, and reproductive toxicity. These can be useful for screening-level risk assessments, including the potential for rapid decision-making, fully utilizing existing knowledge, reasonable conservatism for chemicals used in lower volumes and reduction or elimination of unnecessary animal tests. TTC has found particular favor in the assessment of chemicals used in cosmetics and personal care products as well as other chemicals traditionally used in low volumes. Use of the TTC in environmental safety (termed an eco-TTC) is just beginning, with several recent manuscripts exploring the concept in various applications. Key questions focus on hazard extrapolation of diverse taxa across trophic levels, importance of mode of action, and whether safe concentrations for ecosystems estimated from acute or chronic toxicity data are equally useful and in what contexts. This platform will provide an overview of the theoretical basis for developing an eco-TTC with an initial exploration for chemical assessment and boundary conditions for use. An international collaboration under the ILSI Health and Environmental Sciences Institute has been established to address challenges related to developing and applying useful eco-TTC concepts. \*

#### High Accuracy QSARs for REACH - The need to boost the implementation of Good Modelling Practice

F. Sahigara, CEHTRA SAS; P. Bichere, KREATIS; P. Thomas, CEHTRA SAS  
Good Laboratory Practice (GLP) was implemented by the OECD Member countries to promote the development of quality test data following an internationally harmonised protocol. In recent years, the development of Quantitative Structure Activity Relationships (QSAR) as an alternative to animal testing has grown exponentially. This has been encouraged by ECHA (European Chemicals Agency) who included guidance on use of alternative techniques including *in-silico* methods for the realisation of REACH chemical safety reports, provided the model's validity was demonstrated using the recommended five OECD principles. Despite growing acceptance of QSARs, the majority of existing models are only fit for screening purposes as the information on the data quality used in the original database is often unavailable and the applicability domain is often poorly defined. Nevertheless, advances have been made to improve the transparency in reporting QSARs by the introduction of QSAR reporting formats (QMRF and QPRF) submitted to the regulatory authorities for registration purposes under REACH. As good as these improvements are, they do not meet the same strict standards that are imposed on experimental testing in the laboratory. If *in-silico* models have a future in the replacement of standardised experimental studies, Good Modelling Practice (GMoP) should be implemented and followed by modellers in the same way as GLP to help convince the scientific community of their reliability. This platform presentation will primarily review the state of the science in developing and validating QSARs. The speaker will introduce the concept of High Accuracy QSARs (HA-QSARs), a series of QSAR models of high precision developed to reliably predict several REACH endpoints emphasizing the modelling aspects which make these HA-QSARs advantageous over existing models – *data traceability* and referencing for the training set; *data refinement* via strict data validation using study specific rules and expert judgement; *model development using mechanistically relevant descriptors and an unambiguous modelling algorithm*; *inclusion of all validation techniques* necessary to fill in the QMRF and QPRF and *addressing the uncertainty in prediction* values via confidence intervals and applicability domain assessment. The iSafeRat@HA-QSAR cascade approach (to predict physicochemical and ecotoxicological endpoints) as a high quality validation tool will be presented as a case study.

### 392

#### The utility of QSARs in predicting acute fish toxicity of pesticide metabolites: A retrospective validation approach

n. burden, NC3Rs; S.K. Maynard, Syngenta / Environmental Safety; L. Weltje, BASF SE / Agricultural Centre; J.R. Wheeler, Dow Agrosciences  
Under the EC Regulation 1107/2009 there is a requirement for registrants to establish whether pesticide metabolites are potentially harmful to the environment, and as such fish acute toxicity assessments may be carried out. The number of metabolites can be considerable; therefore this area of testing may use many vertebrates. A recent EFSA aquatic guidance document outlines opportunities to apply non-testing methods such as Quantitative Structure Activity Relationship (QSAR) models. Provision of a scientific evidence base to support the use of QSARs in the prediction of the acute fish toxicity of pesticide metabolites, and subsequent regulatory acceptance, could reduce the numbers of animals used. This work examines the potential for QSARs to be used for pesticide metabolites through a retrospective validation approach. Ecotoxicity data for 679 metabolites contained within the Pesticide Properties Database (PPDB) were extracted and filtered to restrict the dataset to metabolites with experimental fish LC<sub>50</sub> values. QSAR calculations were performed for 190 metabolites using the US EPA's ECOSAR software. In many instances ECOSAR generated more than one predicted LC<sub>50</sub> value, plus a baseline toxicity value. The most conservative of these values was selected for comparison to experimental LC<sub>50</sub> values. The relationship between the predicted and experimental values was assessed. Preliminary analysis revealed a significant correlation between predicted and experimental fish LC50 values ( $r=0.60$ ,  $p<0.001$ , Spearman correlation). For the majority of the metabolites the predicted values were equal to or lower than their associated experimental values. For the remaining values the mean ratio of experimental:predicted LC<sub>50</sub> was 0.24 (SEM 0.03), i.e. QSAR predicted values were on average only 4.1 times higher than those derived experimentally. Considering normal experimental variability, and the risk assessment procedure, these estimates may have regulatory utility. This initial conservative analysis indicates that there is value in further refining the QSAR approach to improve the prediction of acute fish toxicity of pesticide metabolites. Refinements to this analysis will be undertaken before this method can be considered for incorporation into regulatory guidance.

#### A new tool to explore reasons of adverse effects, within a read across perspective

E. Benfenati; M.I. Petoumenou, Istituto di Ricerche Farmacologiche Mario Negri; A. Roncaglioni, Istituto di Ricerche Farmacologiche Mario Negri; F. Como, Istituto di Ricerche Farmacologiche Mario Negri / Department of Environmental Health;

A. Manganaro, Kode srl; A.M. Franchi, Politecnico di Milano; G. Gini, Politecnico di Milano - D.E.I. / DEI

We present here a new program for read across, which displays the similar chemicals and the rules for the common effect of these similar chemicals. The new software is called ToxRead and is freely downloadable at the site: <http://www.toxgate.eu>. It includes a database of chemicals, and for each endpoint it provides the chemicals similar to the target compounds and their experimental value. Collections of rules associated to high/low potency are also present. Chemicals are introduced with the SMILES format. The user can select the number of similar chemicals to be studied. The current version includes modules for a couple of endpoints which are publicly available. One endpoint is genotoxicity (Ames test) and the second one is a model for bioconcentration factor (BCF). Several other endpoints are in the pipeline, and will be presented at the conference. The software shows at the center the target chemical. It is linked to N similar chemicals, represented by circles. In the case of BCF the user can see the plot of the similar compounds and their logBCF and logP values plotted. Rules associated to a certain logBCF value are shown. Typically these are related to certain polar fragments, but other reasons for a particular expected logBCF value are also shown, such as  $\log P < 3$ . The user can see the chemicals similar to the target which contain a certain rule. The similar chemical, its structure, logP, BCF and other available experimental data are also shown. The tool presented in this work has been designed to facilitate the application and visualization of read-across method. Its main advantage is the visual representation of the major evidences available to address a read across with similar compounds facilitating the application of this approach in a regulatory setting. The implementation of a similar approach to address acute fish toxicity and other endpoints is currently ongoing.

#### Hyalella azteca population level endpoints for assessment of toxicological stress

G.L. Ferreira, M.N. Flynn, LEAL Laboratory of Ecotoxicology and Environmental Microbiology School of Technology; G.d. Umbuzeiro, FACULTY OF TECHNOLOGY -UNICAMP / LEAL

The integration of population-level endpoints in the evaluation of toxicological effects of contaminants is considered of greater ecological relevance than the exclusive use of individual-level endpoints. Certain chemicals can affect demographic parameters at concentrations much lower than that indicated by traditional dose-response curve, resulting in population decline and extinction of populations. An offspring generated from ten *Hyalella azteca* couples, a cohort, was followed in baoratory conditions from birth to death of all individuals. From this cohort, life table was constructed and vital parameters obtained. The cohort monitored started with 77 individuals, declining until reaching zero individual, over seven months. The sex ratio was almost even, about 1.08, favorable to males. Reproductive potential of 26.89, generation time of 6.63 and intrinsic rate of increase (rm) of 0.49 were obtained. An alternative endpoint, instantaneous rate of increase (ri) is suggested as an alternative endpoint, easier to work since it is obtained from a partial life table. Toxicol subtle sublethal effects can be discerned through the use as referral of such parameters.

#### The development and application of crustacean biomarkers to monitor reproductive endocrine disruption.

S. Short, G. Yang, Y. Guler, A. Green Etxabe, University of Portsmouth; P. Kille, Cardiff University; A.T. Ford, University of Portsmouth / Biological Sciences  
Despite the well documented cases of endocrine disruption in vertebrates and some molluscan groups, it is currently unknown whether reproductive endocrine disruption represents a threat to crustacean populations. The study of intersexuality provides an opportunity to investigate sexual differentiation and dysfunction. Crustacean intersexuality is associated with contamination and includes forms linked to increased sex-ratio distorting parasites at polluted sites. Despite the importance of crustaceans for monitoring vulnerable aquatic habitats, little is known about the molecular basis intersexuality or any associated sexual dysfunction. To increase the relevance of crustaceans to environmental toxicologists, this study comprehensively analysed gene expression in amphipods presenting parasite and non-parasite associated intersexuality. We suggest existing vertebrate biomarkers of feminisation should not be applied to crustaceans, as orthologous genes are not induced in feminised amphipods. Furthermore, in contrast to vertebrates, where feminisation and intersexuality is often associated with deleterious de-masculinisation, we find males maintain masculinity even when unambiguously feminised. This reveals a considerable regulatory separation of the gene pathways responsible for male and female characteristics and demonstrates that evidence of feminisation (even if detected with appropriate biomarkers) is not a proxy for de-masculinisation in crustaceans. This study has also produced a comprehensive spectrum of potential molecular biomarkers that are currently being applied to specimens collected from clean and industrially impacted locations. This

will represent the first application of appropriate transcriptomic biomarkers to monitor feminisation and de-masculinisation in field populations of crustaceans.

#### **Reproductive and physiological effects of neuro-active pharmaceuticals at low environmental levels in *Daphnia magna***

C. Rivetti, IDAEA CSIC Barcelona / Environmental Chemistry; B. Campos, IDAEA-CSIC / Environmental Toxicology; C. Barata, CSIC / Environmental Chemistry

Assessing the risks of emerging contaminants such as pharmaceuticals in the environment requires an understanding of their exposure regime and their effects at environmental relevant concentrations across species. *Daphnia magna* represents an excellent invertebrate model species to study the mode of action of emerging pollutants, allowing the assessment of effects at different biological levels e.g. molecular, physiological and phenotypic. The present study aims to test the hypothesis that different families of neuro-active pharmaceuticals at low environmentally relevant concentrations may lead to similar phenotypic answers in *D. magna* but through different metabolic signaling pathways. For this aim, life-history studies were complemented with feeding, respiration and survival-starvation assays of exposed females and measurements of energy budget and gene expression. The selected pharmaceuticals were carbamazepine (CBZ), diazepam (DZP) and propranolol (PR), three widely prescribed compounds, already detected at considerable levels in the environment (ng to µg/L). Obtained results indicated that exposure to the studied compounds increased the offspring production but at different concentrations. Enhanced offspring production was food dependent, only occurring at limiting food conditions. Joint effects of tested ternary mixtures were additive and follow the concentration addition model, which may indicate that the studied compounds act on reproduction by similar MoA. Respirometry assays showed that the exposure to CBZ and PR significantly increased oxygen consumption, independently on the presence or absence of food, suggesting an increase in maintenance costs. Survival under starvation revealed a shorter life-span when compared to control. Energy reserves of daphnids were also altered as a consequence of the exposure to these compounds, revealing a shift in the energy allocation of the animals. Analyses of several gene transcripts by qPCR revealed de-regulation in their expression, giving some insights into the molecular mechanisms and MoA of these pharmaceuticals. Overall, this work highlights the use of integrated responses in *D. magna*, combining phenotypic and physiological and molecular endpoints, having great potential to elucidate MoA of emerging pollutants in the aquatic environment. Besides, our results provide consistent evidences on how measured residue levels of these pharmaceuticals in the field are likely to be hazardous to aquatic biota.

397

#### **An inverse U-shaped dose-response for toxicity of pesticide Dipel to *Daphnia magna***

A. de Souza Machado, Leibniz Institute of Freshwater Ecology and Inland Fisheries / Ecophysiology and Aquaculture; C. Zarfl, University of Osnabrueck / Center for Applied Geosciences; W. Kloas, Leibniz Inst. of Freshwater Ecology & Inland Fish.

Dipel is a worldwide used pesticide to control caterpillars in agricultural and urban areas. In most countries, however, there are no water quality criteria for this potential contaminant. Also, negligible toxicity to non-target species has been attributed to Dipel even though there is a lack of dose-response curves and LC50 and EC50 data. Thus, we investigated mortality (for LC50) and immobilisation (for EC50) in neonates and adults of *Daphnia magna* to waterborne Dipel. Biomarkers (global protein, catalase, and chitinase in adults 48h-exposed) and chronic effects (survival and time until the first brood) were also assessed. For concentrations below 10µL Dipel/L toxic levels estimated with TSK method (µL/L) were EC50<sub>24h</sub>=0.20, EC50<sub>48h</sub>=0.17, LC50<sub>24h</sub>=1.17, and LC50<sub>48h</sub>=0.40 for neonates, and EC50<sub>24h</sub>=0.29, EC50<sub>48h</sub>=0.17 for adults. No mortality was observed in adults acutely exposed. Chronic exposure decreased survival (p<0.001) and increased time to first brood (p<0.001) at concentrations as low as 0.10 µL/L. However, all these effects were amended or absent at concentrations higher than 90µL/L. This uncommon inverse U-shaped response curve is similar to the pattern of chronic toxicity of some carcinogenic or endocrine disruptors. Genotoxicity or endocrine toxicity is improbable as main cause of present effects, since daphnids could be acutely immobilised after few minutes of exposure. Biomarkers confirmed disturbances in general health (global protein), oxidative stress (catalase), and growth (chitinase). Such generalized effects suggest existence of a tissue unspecific mechanism of toxicity able to affect the whole organism at once. All biomarkers responded similarly, with increasing and decreasing phases, in which the highest effects occurred around 1-5µL/L and phase changed around 10µL/L. Present results challenge the idea that low toxicity at high concentrations implies low toxicity at lower concentrations. We observed an inverse U-shaped dose-response, with adverse effects at medium and low toxicity was observed at either very high or very low concentrations. Current biomonitoring tools are not efficient to ascribe such effect patterns to causes, and might be the reason why this highly noxious pesticide in our experiments is being used for several decades worldwide and claimed as presenting negligible toxicity. Further studies are needed to clarify Dipel impacts in other organisms and to provide insights on ways to better assess its potential toxicity.

#### **Obesogens beyond Vertebrates: Lipid Perturbation in the crustacean *Daphnia magna***

R. Jordão, Biology; J. Casas, G. Fabrias, IDAEA CSIC Barcelona; B. Campos, IDAEA-CSIC / Environmental Toxicology; B. Pina, IDAEA-CSIC / Environmental Chemistry; M.F. Lemos, Instituto Politécnico de Leiria / Dept Biology; A.M. Soares, Universidade de Aveiro / Department of Biology and CESAM; R. Tauler, IDAEA-CSIC; C. Barata, CSIC / Environmental Chemistry

The increasing concern on emerging contaminants has urged for the need of novel ecotoxicological procedures in Environmental Risk Assessment. Current toxicity assays such as those based on acute and chronic responses may not be sensitive enough to detect emerging effects at low doses. Here we include data on a new assay developed in *Daphnia magna* juveniles to test obesogenic effects of contaminants. The bioassay is based on short term in vivo exposures to the tested chemicals and *in vivo* visualization of lipid reserves using the fluorescent dye Nile red. The test was validated with a model pollutant known to be obesogenic, such as tributyltin (TBT), and other anthropogenic contaminants such as triphenyltin (TPT), bisphenol A (BPA), 4-nonylphenol (NP), di-2-ethylhexyl phthalate (DEPH), piryproxyfen (PP), fenarimol (FEN), methoprene (MET), emamectin benzoate (EM), tebufenozide (TEB), as well as of natural hormones such as methyl farnesoate (MF), 20-Hydroxyecdysone (20E) and ponasterone A (PA.) The results obtained indicated that the Nile red bioassay was able to reproduce lipid reserve dynamics in *D. magna* within and between moulting, reproductive events, juvenile and adult stages, food levels and across the tested compounds. TBT, followed in decreasing order of effects by MF, its insecticide homologous (PP), BPA and 20E increased significantly the formation of lipid droplets measured as Nile red fluorescence. Nonylphenol, fenarimol and emamectin benzoate decreased lipid droplets formation. Lowest effect concentrations in lipid reserves occurred at 0.1-1 µg/L for TBT, PP and EM and at 10-100 µg/L for the rest of substances. Mixture combinations of TBT and 20E with MF or its insecticide agonist PP were synergic, whereas those with FEN or EM were antagonic. These results indicated that there is a great potential for xenobiotics to disrupt the lipid metabolism in *Daphnia* and that such effects are related with the ecdysone, retinoid acid and juvenile receptor signalling pathways. #### **High mutational rates of large-scale duplication and deletion in the environmental toxicology model, *Daphnia pulex***

N. Keith, Indiana University - Bloomington / School of Public and Environmental Affairs; A. Tucker, Southern Arkansas University; C. Jackson, Indiana University Bloomington; W. Sung, Indiana University; J. Lucas Lledo, Leibniz Institute of Freshwater Ecology and Inland Fisheries; D. Schrider, RUTGERS UNIVERSITY; S. Schaack, Reed College; J.L. Dudycha, University of South Carolina / Dept. of Biological Sciences; M.J. Lynch, University of South Florida; J.R. Shaw, Indiana University / The School of Public and Environmental Affairs and The Center for Genomics and Bioinformatics

Knowledge of the rate and spectrum of genomic mutation is critical for understanding an organism's interaction with its environment -including toxic environments; it provides the variation underlying their tolerance, susceptibility, and ability to adapt. Here, we utilize the microcrustacean *Daphnia pulex*, an established ecotoxicological model, to understand the rate and spectrum of genomic mutation. *D. pulex* is a sentinel species, being the primary grazer of algae and main forage of fish in lentic environments, and is an established model in toxicology, evolution, genetics, developmental biology, and ecology. Knowledge of mutational processes in the *D. pulex* genome therefore allows us to understand how *Daphnia* populations, and their corresponding communities, respond to anthropogenic stressors such as pollution and global warming, which have been found to have profound influences on ecosystem health, and are known to influence genomic mutation. Utilizing a mutation-accumulation (MA) experiment, which through relaxing natural selection by the genetic bottlenecking of successive generations allows us to recover nearly all mutations that are not lethal or cause sterility, we find the rates of gene duplication and deletion are over an order of magnitude higher than an other organism, and are driven by large-scale mutations that spontaneously duplicate or delete over 100,000 DNA base pairs, simultaneously changing the copy number of dozens of genes. Furthermore, we find that gene conversion, which occurs during DNA repair of single- and double-strand breaks is rampant in *D. pulex*, and greatly contributes to genome composition.

#### **Multistress in aquatic environments: the big picture (I)**

#### **Sub-lethal effects of acute salinity exposure on stream invertebrates: predation as a case study**

M. Canedo-Arguelles, University of Vic, Spain / BETA Technology Centre

Aquatic Ecology Group; G. Peixoto, FEM Research group University of Barcelona; M. Sala, Universitat de Barcelona / Freshwater Ecology and Management FEM research group; N. Prat, University of Barcelona, FEM Research Group / Ecology; M.D. Faria, CESAM, University of Aveiro / Biology; A.M. Soares, Universidade de Aveiro / Department of Biology and CESAM; C. Barata, CSIC / Environmental Chemistry; B.J. Kefford, University of Canberra / Department of Environmental Science

Salinisation is a growing global threat, recognized as one of the main stressors to freshwater ecosystems. Yet, its effects on the trophic structure of rivers and streams are poorly understood. We conducted a mesocosm experiment to test if elevated conductivities can induce a stress response in the invertebrate predator *Erpobdellidae* reducing its predation efficiency. The experiment was conducted at a flow-through mesocosm of 12 artificial stream channels relying on water pumped from a diversion channel of the Llobregat River (Barcelona, Spain). We used two treatments levels: salt (nominal conductivity = 6 mS cm<sup>-1</sup>) vs. control (nominal conductivity = 0.6 mS cm<sup>-1</sup>), and *Erpobdellidae* presence vs. *Erpobdellidae* absence. Biomarkers were used to test the stress response of *Erpobdellidae* to the salt treatment. Invertebrates were collected from two different substrates in the artificial streams: the stones and the gravel bed. Chlorophyll *a* biomass was estimated as measure of primary production. Results showed that salinity affected significantly ( $P < 0.05$ , Student *t* test) both antioxidant defenses and phase II detoxification metabolism, with reduced catalase activity and increased glutathione *S* transferase activity and induced oxidative stress measured as lipid peroxidation. These results thus indicate that the tested salinity levels could have detrimental effects on *Erpobdellidae* predation efficiency. The presence of predators induced invertebrates to migrate from the stones to the gravel bed, probably looking for refugia. The salt treatment resulted in a reduction of invertebrates' density both in the absence and presence of predators, but only for the communities attached to the stones. Our results suggest that the individuals burrowing in the gravel beds were less exposed to salt toxicity. Chlorophyll *a* (chl *a*) concentrations were highest in the control treatment (no salt and no predators, mean chl *a* = 26.6 mg m<sup>-2</sup>) and lowest in the salt treatment with no predators (mean chl *a* = 7.9 mg m<sup>-2</sup>). The channels in which *Erpobdellidae* were added registered intermediate chl *a* concentrations (mean chl *a* = 17.9 and 14 mg m<sup>-2</sup>, for no salt and salt treatments respectively). This suggests that sub-lethal effects of salinity on *Erpobdellidae* propagated to ecosystem functioning.

#### 401

##### **Does mussel nutritional status act as a confounding factor on biomarkers responses?**

C. González-Fernández, Spanish Institute of Oceanography / Marine ecosystems; M. Albentosa, Instituto Español de Oceanografía / Centro Oceanográfico de Murcia; J. Campillo, Instituto Español de Oceanografía; L. Vinas, Spanish Institute of Oceanography; A. Franco, Instituto Español de Oceanografía; J. Bellas, Centro Oceanográfico de Vigo / IEO (Instituto Español de Oceanografía)

Large scale marine monitoring programs have some difficulties in the assessment of the effect of pollution in the biological responses of the organisms, mainly due to the high temporal and spatial variability of marine ecosystems. One of main differences encountered is the trophic condition which is highly variable when different habitats are monitored. Mussels, such as *Mytilus galloprovincialis*, are extensively used as sentinel species of pollution in marine coastal monitoring programs. From such studies, it has been stated that biological responses caused by pollutants seem to be masked by biological variables as mussel condition. The main objective of this study was to determine the relative importance of two variables: food availability and the presence of toxicants, on some biochemical biomarkers. Three experimental trophic conditions were simulated by regulating daily food ration of mussel for 45 days: low food condition (N1), medium food condition (N2) and high food condition (N3) which promoted negative, maintenance and positive mussel energy balances, respectively. In all cases, mussels were exposed to two nominal fluoranthene (FLU) concentrations (3 and 60 µg L<sup>-1</sup>), for 3 weeks. Results showed that several biomarkers were affected by mussel nutritional status (SOD, CAT, GPx and GST) evidencing the same behavior: nutritional stressed mussel (N1) had the highest enzymatic activity, contrary to N3-mussels which showed the lowest enzymatic activity. Furthermore, FLU exposure also impact biomarker responses. In this case, GR and GPx evidenced an increase at low FLU concentrations. Contrary, GST exhibited the highest value at high FLU concentrations. Two important metabolic processes could be the responsible of this behaviour. On the one hand, nutritive-stressed mussels seems to be more resistant to pollution than well-fed mussels, and on the other hand, it seems that some biomarkers have an "hormetic response" to FLU consisting in a low-concentration biomarker stimulation not observed at higher FLU concentration. The results obtained in this study, highlight the fact that the nutritional status could be more relevant than the effect of pollution in some biomarkers commonly used in monitoring programs. Therefore, it needs to be considered in large scale monitoring programs where both stressors, pollution and great variability of food conditions can be interacting.

#### 402

##### **Sensitivity of Pacific oyster embryos (*Crassostrea gigas*) to combine effects of pollutants and salinity**

P. GAMAIN, EPOC; P. Gonzalez, Géochimie Et Ecotoxicologie des Métaux dans

les systèmes Aquatiques GEMA team UMR CNRS Université Bordeaux; J. Cachot, Université Bordeaux / EPOC; B. Morin, EPOC

The Pacific oyster represents the world's aquaculture production, with 4.6 million tons produced in 2006. France is the fourth world producer of oysters and *Crassostrea gigas* is the principal cultivated species in the Arcachon bay. However in recent years, problems of recruitment, capture and mortality of juvenile or adult oysters occurred. The increased frequency of these events can be indicative of changes in the global quality of the Arcachon bay. Previous studies have highlighted the presence of many plant molecules, with significant concentrations in water, mainly herbicides such as metolachlor and its metabolites, and "anti-fouling" as copper. Due to global warming, the Arcachon bay is facing other environmental problems such as increase of surface water temperatures and/or salinity fluctuations. Previous studies have highlighted that early life stages of marine invertebrates are sensitive to environmental changes. Therefore, in the context of global climate change, vulnerability of D-larval stages of *C. gigas* to salinity and pollutants was investigated. Embryotoxicity bioassay has been used. Male and female oysters of a commercial hatchery were induced to spawn by thermal stimulation. Eggs were fertilized with sperm to obtain embryos. Effects of copper (0.5 µg.L<sup>-1</sup>, 1 µg.L<sup>-1</sup> corresponding to environmental concentrations, 10 and 50 µg.L<sup>-1</sup>) and metolachlor (10 ng.L<sup>-1</sup> corresponding to environmental concentration, 100 and 1000 ng.L<sup>-1</sup>) on the early life stage of Pacific oyster D-larvae were examined at various salinities (18 ; 21 ; 24 ; 27 ; 30 ; 33 ‰). After 24h, developmental abnormalities of D-larvae were analyzed. Significant increases of the percentage of abnormal D-larvae were observed from 0.5 µg.L<sup>-1</sup> of copper and 10 ng.L<sup>-1</sup> of metolachlor in comparison with respective controls. The current study suggests that copper, and metolachlor can induce larval abnormalities in a population of exposed oysters at environmentally relevant concentrations. The low feasibility limit of the embryo-larval test is around 24 ‰ of salinity. With copper, at all concentrations tested, salinity does not impact the percentage of larval abnormalities whereas, with metolachlor, larval abnormalities increase significantly with decreasing salinity.

#### 403

##### **Biotransformation of selected azole fungicides in the aquatic invertebrate *Gammarus pulex* and their effects in mixture on oxidative drug metabolism**

A. Rösch, Eawag / Environmental Chemistry; S. Anliker, Eawag Swiss Federal Institute of Aquatic Science and Technology / Environmental Chemistry; J. Hollender, Eawag / Environmental Chemistry

Xenobiotics, such as pesticides and pharmaceuticals are distributed ubiquitously in the aquatic environment and their co-occurrence is often reported. One class of fungicides are azoles including triazoles and imidazoles. They act by inhibiting the ergosterol biosynthesis in fungi. In non-target organisms it was observed that azoles can enhance the effect of other pesticides by inhibiting the cytochrome P450 monooxygenases, active in detoxification of xenobiotics. Binding between azole and enzyme occurs via the nucleophilic nitrogen in the specific azole moiety. Thus, biotransformation reactions taking place at the active moiety of the fungicide can greatly influence their inhibitory potential. In this study, triazoles (cyproconazole, epoxiconazole, fluconazole, propiconazole, tebuconazole) and imidazoles (ketoconazole, prochloraz) were chosen in order to investigate biotransformation reactions taking place in the aquatic invertebrate *Gammarus pulex*. *G. pulex* were exposed to the fungicides at concentrations of 200 µg L<sup>-1</sup> for 24 hours. To assess the inhibitory potential of selected azoles, a second experiment was performed where *G. pulex* were exposed to a pesticide mixture (prochloraz and azoxystrobin) and to a pharmaceutical mixture (ketoconazole and tramadol). Samples were analyzed with online solid phase extraction coupled to LC-tandem high resolution mass spectrometry. Isotopic pattern and MS/MS spectra were used to identify suspected biotransformation products (BTPs). Most identified biotransformation reactions (hydroxylations, dealkylations, cysteine and sulfate conjugations) took place at the nonazole moiety. Only for the imidazole fungicides changes at the imidazole ring were observed, resulting in a loss of the active moiety. However, the measured BTP concentrations inside the organism were quite low, indicating that formed BTPs are of less importance in terms of enzyme inhibition. For the pesticide mixture a strong inhibitory effect was observed exhibited by less formed BTPs and higher mortality, whereas in the mixture with ketoconazole no significant effect was noted, which is different to investigations in humans. Although the concentrations used in this study were relatively high, it is likely that co-occurrence of azoles with other organic contaminants can lead to increased toxicity of already highly toxic compounds. Therefore, further research is important to understand their different potencies in aquatic organisms.

#### 404

##### **Physiological responses in freshwater bivalves to microcystin-LR and Roundup Flash®**

C. Wiegand, University of Southern Denmark / Department of Biology; M. Götze, University of Southern Denmark; M. Malecot, Université Rennes / UMR Ecobio; B. Guevel, C. Pineau, Proteomics Core Facility Biogenouest / IRSET Inserm U Lakes, ponds and rivers adjacent to farmland face exposition to agrochemicals and fertilizers. Excess plant nutrients are drivers for cyanobacterial blooms, which pose a natural environmental risk due to their capacity to produce toxic metabolites. The cyanobacterial toxin microcystin-LR binds and inactivates protein phosphatase of type 1 and 2A, and may cause death of the organism. Within exposure

concentration and duration limits, microcystins can be detoxified via conjugation to glutathione by glutathione S-transferase (GST). Glyphosate is one of the most used herbicides worldwide, it inhibits the amino acid synthesis in plants through the shikimic acid pathway. Evidence about its harmful effects in non-target organisms is growing, in particular for the commercial formulations. Freshwater mussels are sessile organisms and via their filtration for food exposed to huge quantities of water. Whereas some indigenous species densities decline, invasive ones proliferate in the same pollution scenario. This study presents comparisons of invasive and indigenous mussel species in biotransformation of microcystin-LR and the herbicide Roundup Flash® (containing Glyphosate) and energy allocated to that. Moreover, variations of the total proteome were investigated. The invasive *D. polymorpha* detoxified microcystin-LR up to 50 µg/L<sup>1</sup> via the sGST system but *U. tumidus*' sGST were rather inhibited in the same exposure scenario. Moreover, GST was hampered in both indigenous species (*U. tumidus* and *U. pictorum*) by Roundup Flash®: it slightly decreased the GST activity, and prevented the elevation, thus the detoxification capacity in the mixed exposure. Energetic resources supported the detoxification processes but the species drew from different sources: Whereas *U. tumidus* started by using glycogen, supported by lipids after 7 days of exposure, *U. pictorum* needed the lipids and thus more energy right from the start. Even if closely related, these species may experience different life trait consequences via the energy that is allocated to detoxification and mending, thus lacking for growth and reproduction. Using de novo sequencing, 30 spots were identified by mass spectrometry. Effects for both substances were evidenced at environmental realistic concentrations. Enzymes related to antioxidant and detoxification processes were often down regulated, indicating an impairment of the mussels' capacity to react to environmental stress.

#### Multi-contamination related to variations in thyroid endocrine status of wild European eels (*Anguilla anguilla*) from the Loire estuary (France)

M. Couderc, Université de Nantes; J. Marchand, Maine University / MMS EA; A. ZALOUK-VERGNOUX, Université de Nantes; A. Kamari, Université de Nantes; B. Moreau, University of Maine / MMS EA; I. Blanchet-Letrouve, MMS EA; B. Le Bizec, ONIRIS / LABERCA; C. Mouneyrac, Université Catholique de l'Ouest / MMS EA; I. poirier, MMS EA

In teleosts, thyroid function has been involved in multitude of critical physiological process. Given the complexity of the hypothalamo-pituitary-thyroid (HPT) axis, a large number of genes and proteins can be the potential target of endocrine-disrupting compounds (EDCs). The aim of this study was to evaluate, in yellow and silver European eels (*Anguilla anguilla*), potential effects on thyroid status by analyzing the associations between EDC body burdens and thyroid hormones (THs). In silver individuals, expression of a series of genes involved in the HPT axis was also investigated. In yellow individuals, high FT3/FT4 ratios and low plasma FT4 level were associated with higher concentrations of PCBs and PBDEs, as underlined by significant correlations with many congeners. Fewer positive relationships with alkylphenols (APs) were also noticed. In contrast, silver eels exhibited significantly less correlations between THs and contaminant loads. This result could be related to their lower thyroid activity but also to the remobilization of contaminants supposed to occur during sexual maturation. Concerning mRNA expression, main correlations were noticed, in silver females, for thyroid-stimulating hormone (TSHβ) gene expression which was significantly correlated to numerous PCBs and for hepatic mRNA levels of deiodinase 2 (Deio 2) which showed to be negatively correlated to 2-OHF and 2-OHNa. Thyroid receptor (TRα and TRβ) mRNA levels exhibited some weak negative correlations with few PBDEs in silver females and males. Hepatic vitellogenin (Vtg) mRNA levels were detected in all silver males but at a lower level than silver females. In males, Vtg mRNA levels were associated to increased FT4/TT4 ratio and to 2 PCB congeners but in an opposed way. In silver females, strong positive correlations were found with several congeners of PCBs, PBDEs and PFAS suggesting potential estrogenic effects. Taken together, the observed results indicate that several organic contaminants could disorder TH homeostasis in eel, via the disruption of the peripheral deiodination and/or metabolism of T4 and the induction or inhibition of TSHβ, Deio 2 and Vtg gene transcription.

#### Wildlife ecotoxicology from molecular to population effects (II)

406

#### Blood metals (Cd, Pb, Hg and As) in Griffon vulture (*Gyps fulvus*) and Black vulture (*Aegypius monachus*) from Extremadura (Spain)

F. Soler, M. Pérez López, University of Extremadura / Faculty of Veterinary Medicine; S. Sánchez Cuerda, Los Hornos Wildlife Recovery Center - Junta de Extremadura; I. de la Casa Resino, University of Extremadura / Faculty of Veterinary Medicine

Birds are continuously exposed to environmental pollution and toxic metals have been suspected as an important factor contributing to the decline of their populations. Vultures are on the top of the food web and are distributed over a wide geographical range; thus, they can be potentially convenient species to study the effects of xenobiotics. The present study aims to evaluate the concentration of four toxic metals (Cd, Pb, Hg, As) in blood of 51 Griffon vultures (Gv) and 15 Black

vultures (Bv) sampled in Extremadura (Spain) during the years 2013 and 2014. Metal analysis was performed using ICP-MS technique. The detection limits were 0.25, 0.21, 3.01 and 0.5 µg/L for Cd, Pb, Hg and As, respectively. Recoveries were >92 % and coefficients of variation were lower than 6.5%. Total mean values for both species were 200, 3.32 and 7.06 µg/L for Pb, As and Hg, respectively. Cd were not detected in any analyzed sample. Considering both species, the Gv presented the highest levels of Pb, being the Bv the one with higher levels of Hg and As. Regarding Pb levels, it has been considered that background blood concentration in birds is

407

#### Factors affecting blood lead (Pb) concentration in griffon vultures: a spatially explicit prediction

P. Mateo-Tomás, Instituto de Investigación en Recursos Cinegéticos (IREC) CSIC-UCLM-JCCM; P.R. Camarero, I.S. Sanchez-Barbudo, UCLMCSIC; P.P. Olea, Instituto de Investigación en Recursos Cinegéticos; R. Mateo, U.C.L.M.-C.S.I.C. / Instituto de Investigación en Recursos Cinegéticos Lead (Pb) toxicity poses a significant threat for the conservation of many species. We determined blood Pb exposure in griffon vulture (*Gyps fulvus*) by assessing blood Pb concentration (ng/ml) from 691 individuals captured in 2008-2012 at 27 feeding points in Aragón, NE Spain. We performed (generalized linear and cumulative link) mixed models to identify the main factors influencing blood Pb concentration. This information was further used to produce spatially explicit maps of Pb exposure for the species. Almost half of the sampled vultures (i.e. 44.9 %) were Pb-exposed (i.e. blood Pb concentration >200 ng/ml). The best model correctly predicted blood Pb concentration for 68.6% of the individuals considered for modelling (i.e. 589 vultures with complete information for all the considered variables). Soil pH (highly correlated with soil Pb levels) was the main variable explaining vulture Pb exposure. Poultry supplies to feeding points negatively influenced blood Pb concentration, which was higher in males than in females. Vulture Pb exposure seemed to be higher in winter than in summer, maybe responding to a higher presence of additional lead sources (e.g. big game hunting remains) in autumn and winter. The high prevalence of Pb-exposed griffon vultures in the study area (44.9%) seems to be mostly due to soil Pb bioavailability favouring Pb presence in vultures' main food resources (i.e. livestock and wild animals). This elevated blood Pb background can increase the effects of additional point Pb exposures like Pb ammunition from game carcasses. Managers can take advantage of the maps here produced to identify those areas under higher risk of Pb exposure for vultures (and other scavengers) and take action to limit exposure to potential Pb sources (e.g. big game hunting remains).

408

#### Monitoring the impact of new UK stewardship on SGAR exposure in non-target wildlife

R.F. Shore, Centre for Ecology & Hydrology (NERC); P.A. Henrys, Centre for Ecology and Hydrology; L.A. Walker, Centre for Ecology & Hydrology Residues of second-generation anticoagulant rodenticides (SGARs) have been detected in non-target species around the world, raising concerns over the environmental impacts of these compounds. In Britain, five SGARs have been licensed for use but, until now, the three most acutely toxic compounds (brodifacoum, flocoumafen, difethiolone) have been restricted to indoor use to limit potential secondary poisoning of non-targets; outdoor use has been permitted only for bromadiolone and difenacoum. However, the regulatory position in Britain has recently been revised and authorisations for professional use will change such that all five SGARs can be used in and around buildings. Open area use is also likely to be authorised for some compounds. These changes will require compliance with a stewardship scheme designed to enhance best practice and reduce non-target exposure. These changes in authorisation may alter exposure and risk to non-targets, but the direction of change may depend on the effectiveness of and compliance with stewardship. How can any such changes be measured? The Predatory Bird Monitoring Scheme (PBMS – <http://pbms.ceh.ac.uk>) has monitored liver SGARs in barn owls (*Tyto alba*) for more than 20 years. This large, unique dataset has provided a baseline against which the effects on non-target exposure from changes in authorisation can be judged. We analysed our baseline data to determine the sensitivity with which changes in exposure could be detected. The liver residue data for individual compounds and summed SGARs were not normally distributed, necessitating that we split the data into two normally distributed groups for each compound (< 100 ng/g and > 100 ng/g wet wt). These groups can be considered “background” and “toxicologically significant” respectively. We predict that analysis of 100 birds/yr should enable detection of changes of 20% from baseline for individual compounds within 1-4 years (95% confidence limits) and a change of 50% in summed SGARs within a year. Such changes, together with consideration of the proportion of birds with “background” and “toxicologically significant” residues, can be used as potential target or trigger values to determine the impact of stewardship and if further changes to authorisations are needed, respectively.

#### Does biodiversity impact the transfer of pollutants in ecosystems?

F. Raoul, University of Franche-Comté / CNRS / UMR 6249 Chrono-environnement; S. Ozaki, University of Franche-Comté/CNRS /

ChronoEnvironnement; S. Drouhot, UMR 6249 Chrono-environnement; B. Valot, University of Franche-Comté/CNRS / ChronoEnvironnement; F. Mora, Conservatoire Botanique National de Franche-Comté - Observatoire Régional des Invertébrés; T. Cornier, Centre régional de phytosociologie agréé Conservatoire Botanique National de Bailleul; R. Scheffler, University of Franche-Comté / ChronoEnvironnement

Trophic links nests the transfer of energy and matter as well as the transmission of pollutants and pathogens within food webs. There are studies demonstrating that the number of trophic levels ("vertical" diversity) is a key factor in the bio-magnification of some pollutants along the food chains, but the importance of community diversity within a given trophic level ("horizontal" diversity) on the transfer of contaminants to a higher trophic level is still an open question. The aim of this study is to correlate the trace metals (TM) exposure of the wood mouse (*Apodemus sylvaticus*) to the resource community diversity both in the field and in the diet of the animal. Sampling took place in the surroundings of the former Metaleurop Nord Pb and Zn smelter in northern France. In 500m x 500m sampling squares vegetation was quantified and mapped, invertebrate fauna was sampled using pitfall traps and colored plates and small mammals were trapped using small break-back traps. The stomach contents (SC) of the rodent were extracted and used for quantification of TM by ICP-AES/MS and for molecular identification of food items by using DNA metabarcoding. Primers were chosen to amplify plant, mollusc, arthropod, earthworm, and fungi DNA. Exposure to Cd, Pb and Zn was significantly lower in September than in April. The taxonomic richness of both plant and invertebrate food items in SC was significantly higher in September than in April, contrasting with the pattern observed for their availability in the field. Significant but weak relationships between TM concentrations in SC and food item richness in SC were detected in April for Pb (with both plant and invertebrates richness) and for Cd (with total food item richness). No correlation was detected in September and for Zn. Our results suggest that the link between biodiversity and exposure is TM-specific and not straightforward. Further analyses will focus on resources' life history traits related to TM accumulation capacity.

410

#### **Can long-term exposure to trace metals (Cd, Pb) induce fluctuating asymmetry in wild wood mice (*Apodemus sylvaticus*)?**

N. Tete, University of Franche-Comté / ChronoEnvironnement; F. Muñoz-Muñoz, Universitat Autònoma de Barcelona / Departament de Biologia Animal; C.C. Fritsch, CNRS / UMR ChronoEnvironnement; R. Scheffler, University of Franche-Comté / ChronoEnvironnement; A. Sánchez-Chardi, Autonomous University of Barcelona / Microscopy Facility

Trace metal contamination can have deleterious effects on foetal health by altering gene expression and modulating the target phenotype of an individual. Fluctuating asymmetry (FA), defined as subtle random deviations from perfect bilateral symmetry, has been proposed as a quantitative biomarker to detect stress during the developmental period. In this context, the aim of the present work was to evaluate the effect of long-term TM contamination on developmental stability of a wild population of wood mouse (*Apodemus sylvaticus*). The field work took place in the surroundings of an ancient lead (Pb) and zinc (Zn) smelter. After more than 100 years of activity, this area is drastically polluted, mainly by three TM: cadmium (Cd), Pb, and Zn. Categories of environmental contamination (control, lightly, moderately and highly polluted) were determined depending on Cd concentrations in the soils. In spring 2011, 61 mice were live-trapped along a pollution gradient of contamination. Metal concentrations (Cd, Pb) in soft tissues (liver and kidneys) were measured in each individual by. To estimate size and shape FA, 17 two-dimensional landmarks were digitized on each right and left mandible. Histological alterations attributable to chronic TM exposure were also assessed in the liver and the kidneys of mice. Results indicated an important transfer from the environment to the biota. Concentrations of Cd and Pb in the liver increased along the gradient of contamination ( $F = 18.1$ ,  $df = 3$  and  $57$ ,  $p < 0.001$  for Cd and  $F = 9.4$ ,  $df = 3$  and  $57$ ,  $p < 0.001$  for Pb). Preliminary results indicate a trend for size FA ( $F = 1.8$ ,  $df = 3$  and  $57$ ,  $p = 0.157$ , Fig. 2) but not for shape FA ( $0.263 < p < 0.811$ ) to increase along the gradient of contamination. No correlation could be established between TM concentrations in soils or in target organs and FA shape or size ( $0.162 < p < 0.851$ ). Size FA correlated with the general state of the kidneys in mice (Spearman's rank correlations  $r_s = 0.27$ ,  $p = 0.036$ ) and more specifically with the severity of necrosis in the kidney tissues (Spearman's rank correlations  $r_s = 0.34$ ,  $p = 0.008$ ). Shape FA was also related to the severity of fibrosis in kidneys (Spearman's rank correlations  $r_s = 0.29$ ,  $p = 0.026$ ). These preliminary results show that measures of developmental instability are less sensitive to detect TM pollution impact on wood mice than other biomarkers quantified such as the histopathological evaluation.

411

#### **Imaging of structural and ultrastructural effects of chronic exposure to Pb and Cd in liver of wood mice, *Apodemus sylvaticus*: qualitative and quantitative approaches**

A. Sánchez-Chardi, Autonomous University of Barcelona / Microscopy Facility  
Chronic exposure to non-essential trace metals (TMs) produces toxic effects in target tissues and cells that may be detected by morphological changes at structural and ultrastructural levels. TMs induce toxic effects in liver that may be observed on the entire organ or in its cells such as changes in volume and size, inflammatory and

carcinogenic processes, cell death, cell degeneration, nuclei damage, or mitochondrial impairment among others. In the present study, we compared for the first time the damages of chronic exposure to different environmental levels of lead (Pb) and cadmium (Cd) in wood mice, *Apodemus sylvaticus*, at tissular (hepatic tissue) and cell (hepatocytes) levels using qualitative and quantitative approaches. These morphological quantifications were compared with TM levels in liver as biomarker of effect in wood mice, *Apodemus sylvaticus*, a species often studied as a bioindicator of environmental pollution. During spring 2011, 84 wood mice were live-trapped around the former smelter. TM concentrations (Cd, Pb) in liver were measured in each individual by furnace atomic absorption spectrometry and expressed as mg/kg dry mass. The alterations attributable to metal exposure in hepatic samples were analyzed using both conventional techniques of light microscopy and transmission electron microscopy. The concentrations of Cd and Pb in the liver differed significantly along the gradient of contamination. The qualitative and quantitative approaches at tissular and cellular levels showed increases of frequency, extension of lesions and severity of several hepatic alterations related to chronic exposure to TMs. More specifically, the necrosis and cell degeneration of hepatocytes were correlated with both the concentrations of Cd and Pb in soils. The qualitative and quantitative approaches at cell level in healthy hepatocytes revealed an increase of glycogen accumulation and mitochondrial damage in mice from the polluted sites. These preliminary results point out in the important metabolic effects of TMs exposure in two crucial functions for cell energy as the storage of glycogen as rapid energy source and by cellular respiration in mitochondria. The disturbances in crucial cell functions of liver, the main target organ for many pollutants including TMs, detected in mice exposed to Pb and Cd, indicate relevant toxic effects that may have a deleterious impact on physiological functions of wild individuals exposed to anthropogenic stressors.

#### **Innovations in environmental analytical chemistry: the quest for pollutants using target and non-target approaches (I)**

#### **Development and validation of a LC-MS/MS method for the determination of surfactants in wastewater treatment plant using QuEChERS and solid phase extractions**

A. Bergé, Institut des Sciences Analytiques; B. Giroud, L. Wiest, Institut des Sciences Analytiques UMR TRACES Team; E. Vulliet, CNRS  
Because of their specific physicochemical properties (amphiphilicity, solubility in polar and non-polar liquids, ability to form micelles, etc) surfactants are widely applied in industry and in the household. One of the main pathways of their introduction in the environment is their rejection by treatment plants. As their applications are on a very large scale, it has therefore become necessary to reach a more detailed understanding of their environmental fate. The analysis of complex matrix such as effluents or sludges needs a rigorous sample preparation to obtain repeatable and selective analysis. The usual techniques are liquid-liquid extraction (LLE), solid phase extraction (SPE), or accelerated solvent extraction (ASE). Additionally, innovative techniques such as liquid-liquid extraction assisted by salts (QuEChERS) may be considered. Nowadays, high-performance liquid chromatography (HPLC) is usually coupled with a mass spectrometry detector (MS) (or tandem mass spectrometry detector MS-MS), what allows for detection, identification and quantification of the various compounds in various environmental matrices. This work describes particularly the separation and determination of several classes of surfactants as quaternary ammoniums, betains, alkylphenol ethoxylated, linear alkylbenzene sulphonates, sodium sulphates, and alcohol polyethoxylated using tandem mass spectrometric detection. This work leads to innovative and validated analytical methods to detect and estimate several classes of detergents in wastewaters and solid matrices. This work has confirmed, first and foremost, that surfactants are indeed highly concentrated in urban environment. Although biological process removed a significant proportion of the total pollution, concentrations in final effluents remain significant, up to 100 µg/l. The coupling of a powerful analytical method with the QuEChERS extraction achieved the necessary selectivity and sensitivity to the detection of these compounds at low levels, below the ng/g.

413

#### **Levels and fate of antimycotic pharmaceuticals at sewage treatment plants**

J. Casado Agrelo, Analytical Chemistry; G. Castro, University of Santiago de Compostela; I. Rodríguez, University of Santiago de Compostela / Department of Analytical Chemistry Institute of Food Analysis and Research; M. Ramil, R. Cela, University of Santiago de Compostela

Antimycotics are a broad group of drugs recognized as emerging environmental contaminants. These pharmaceuticals are active against infections caused by fungi and they are suspected of being endocrine disruptors. In this work we present the optimization of improved selectivity extraction and enrichment methods for the analysis of antimycotic drug residues in water and sludge samples using a liquid chromatography quadrupole time-of-flight mass spectrometry system. Analytes extraction and concentration from water samples was performed using a mixed-mode (reversed-phase and cationic exchanger) solid-phase extraction cartridge followed by a sequential elution protocol. As a result, the efficiency of electrospray ionization was similar for calibration standard solutions and sample

extracts, even in case of raw wastewater. Other variables related with the efficiency of the extraction step, such as sample pH and potential losses during sample filtration, were also optimized. Improving the performance of previous sample preparation methods, and attaining limits of quantification low enough to deal with environmental samples. Regarding sludge samples, an effective and selective, modular sample preparation method for the extraction of the pharmaceuticals was proposed. It consisted on a matrix solid-phase dispersion (MSPD) extraction performed in a syringe on-line connected with a cationic exchanger SPE cartridge. In comparison with previously published sample preparation methodologies, the developed approach greatly simplifies sample handling and reduces attenuation of ESI ionization for sample extracts when compared to standard solutions. The obtained absolute recoveries ranged between 75 and 117% in water samples, and between 70 and 118% in the case of sludge samples. Limits of quantification of the method varied between 2 and 15 ng L<sup>-1</sup> in water samples, and between 5 and 8 ng g<sup>-1</sup> in the case of the sludge samples. Fluconazole, ketoconazole, miconazole and clotrimazole were measured in wastewater samples at concentrations up to 200 ng L<sup>-1</sup>, while climbazole, ketoconazole, clotrimazole and miconazole were ubiquitous in urban sludge samples, with maximum average concentrations (above 400 ng g<sup>-1</sup>) corresponding to clotrimazole.

414

#### High-resolution mass spectrometry approaches for tracking down transformation products of diclofenac and structurally related non-steroidal anti-inflammatory drugs (NSAIDs) in wastewater

S. Perez, IDAEA-CSIC / Environmental Chemistry

Over the last five years, liquid chromatography-high resolution mass spectrometry (LC-HRMS) has emerged as a promising technique for qualitative methods. HRMS can provide a great deal of information from the full-scan acquisition allowing the confirmation of the identity of each analyte using accurate mass and isotope cluster of the molecular ion. Of particular value, however, is mass spectral information on fragment ions which can be generated using platform-specific functions. Therefore, this technique can be of great interest for the application of new approaches for the identification of transformation products (TPs) of polar compounds such as non-steroidal anti-inflammatory drugs (NSAIDs) in environmental samples. NSAIDs are a chemically heterogeneous large group of drugs used primarily to treat inflammation and fever. They reach the WWTPs after their use in human medicine. Compared to the data dealing with the fate of NSAIDs in the environment, very little evidence has been published as regards metabolic pathways in complex microbial communities like those encountered in tank of the activated sludge treatment. In a previous work, in the same set-up related in this work, we have tentatively identified nitroso (TP324) and nitro (TP340) derivatives of diclofenac (DCF). The current work intended to investigate still uncovered aspects in the environmental fate in WWTP of the NSAIDs related to DCF such as meclofenamic acid, flufenamic acid, tolfenamic acid, and lumiracoxib identifying their TPs. By applying HR-MS in the analysis of complex samples, the detection and identification of the TPs was greatly facilitated: following the assignment of elemental formulae based on exact mass, relative isotope abundances and isotope spacing, the interpretation of characteristic product ion spectra acquired on the QExactive allowed to identify the most likely sites of structural modifications in the TPs. Biodegradation experiments in batch-reactors loaded with mixed liquor demonstrated that similar degradation profiles were observed for the related compounds of DCF. In the batch reactors, we have reported the discovery of unusual microbial nitro/nitrosation TPs of related NSAIDs of DCF. These results are consistent with our previous hypothesis of DCF transformation through biological reactions to generate these TPs in lab-scale reactors and also with the first evidence of the occurrence of these TPs in WWTPs, reported in other work of our group.

#### Biogenic, non-extractable residues of pesticides

C. Possberg, RWTH Aachen University / Institute for Environmental Research Biology V; B. Schmidt, RWTH Aachen University; M. Telscher, BayerCropScienceEnvironmental Fate / DevelopmentEnvironmental Safety; D. Schaefer, Bayer CropScience / Environmental Safety Environmental Fate; A. Schaeffer, RWTH Aachen University / Institute for Environmental Research After the application of pesticides, residues are formed in plants and soil, which cannot be extracted with organic or in-organic solvents without destruction of the matrix and/or the chemical compound. While quantification of non-extractable residues (NER) is feasible by use of radioactively labelled compounds, direct analysis of the chemical nature of NER is not possible. Because microorganisms use carbon both directly from the contaminants and indirectly, following mineralisation and fixation of CO<sub>2</sub> released from the xenobiotic, parts of the <sup>14</sup>C-labelled carbon atoms may be incorporated into microbial biomass. After cell death, dead biomass is incorporated in SOM (soil organic matter) thus forming biogenic NER (bioNER) which is unlikely to pose any risk to the environment. The formation of bioNER is not yet measured routinely in environmental fate studies of xenobiotics due to a lack of methodology (Kaestner et al, 2014). This investigation focusses on proteinaceous carbon analysis because proteins make up the largest portion of the bacterial cells, namely 50-55% of the microbial mass. The main goal of the experiments was to develop a rapid and reproducible method for quantifying bioNER based on <sup>14</sup>C-analyses. Amino acids are known as microbial markers,

which represent most of the analytically detectable biogenic components of SOM. Quantification of the magnitude and kinetics of the formation of biogenic residues during microbial degradation of the model substance bromoxynil in soil was examined. The <sup>14</sup>C-distribution within the system was analysed in order to establish a mass balance comprising CO<sub>2</sub> formation, solvent-extractable residues, total NER and bio-NER. In soil treated with <sup>14</sup>C-bromoxynil after 57 days of incubation significant amounts (approx. 60% of applied) of NERs are formed. Mineralisation occurred in amounts up to 23% of the applied radioactivity. For further characterisation of the NER fraction after extraction amino acids were separated by two-dimensional TLC and visualised by reaction with ninhydrin. Radioactive marked amino acids which have been formed during incubation were visualised by bioimaging and assigned to the corresponding reference amino acids. In addition the isolated amino acids were analysed by GC-MS and HPLC-fluorescence/-radiodetection. Reference: Kästner M, Nowak KM, Miltner A, Trapp S, Schäffer A (2014). #### Pharmaceuticals in the freshwater invertebrate, *Gammarus pulex*, determined using pulverised liquid extraction, solid phase extraction and liquid chromatography-tandem mass spectrometry

T.H. Miller, Kings College London / Analytical and Environmental Sciences; G. McEneff, Dublin City University; R.J. Brown, wca consulting; S.F. Owen, AstraZeneca / Safety Health Environment; N.R. Bury, Kings College London / Division of Diabetes and Nutritional Sciences; L. Barron, Kings College London / Analytical and Environmental Science

Pharmaceuticals and their metabolites are continually discharged into aquatic environmental compartments via sewage treatment plant effluents leading to a pseudo-persistent exposure of aquatic life. These compounds may have adverse effects on reproduction, development and behaviour in biota.<sup>1</sup> As water concentrations of pharmaceuticals vary temporally, the exposure of biota to contaminated waters will remain in a constant flux thus highlighting the importance to determine internal concentrations for environmental risk assessment (ERA)<sup>2</sup>. However, determination of pharmaceutical and personal care products at trace levels in biota remains analytically challenging. Herein, we present a new analytical method for the confirmatory identification and quantification of 10 pharmaceuticals in the aquatic invertebrate, *Gammarus pulex*. Collected Gammarids were weighed, washed, freeze-dried at -50 °C and homogenised before extraction in 5 mL acetonitrile in a ball-mill extraction vessel. Extracts were then purified and concentrated by solid phase extraction using a Waters Oasis HLB sorbent (200 mg, 6 mL barrel). Extracts were analysed using an optimised reversed-phase liquid chromatography-tandem mass spectrometry method in positive and negative electrospray ionisation modes. Method performance data is also presented herein showing acceptable linearity (R<sup>2</sup> ≥ 0.98; range from 10 ng/g to 10 µg/g dry weight in most cases), reproducibility (RSD ≤ 20 %) and limits of quantification (4-45 ng/g). This method was successfully applied to the trace determination of several pharmaceuticals present in *G. pulex* across multiple river locations in the South London area at ng/g concentrations showing that the method was fit for purpose. Occurrence of xenobiotic residues in surface water from each site is also shown. This study shows that xenobiotic contamination was present in *Gammarus pulex* and can potentially direct future environmental risk assessment (ERA) strategies. #### Assessment of polyfluorinated substances in Antarctic seabird plasma: a new methodology based on on-line solid phase extraction coupled to HPLC-MS/MS using small sample volume

G. Munoz, LPTCEPOC 5805 CNRS / UMR EPOC LPTC; P. Labadie, University of Bordeaux / UMR EPOC Equipe LPTC; P. Pardon, University of Bordeaux / UMR CNRS 5805 EPOC-LPTC; S. Tartu, Ecophysiology; O. Chastel, Centre d'Etudes Biologiques de Chizé CEBC CNRS UPR; H. Budzinski, University of Bordeaux / UMR EPOC Equipe LPTC

Polyfluorinated substances (PFASs) are man-made chemicals that have been in use since the 1950s due to their excellent tensioactive properties. However, several PFASs have been reported to exhibit persistent, bioaccumulative and toxic properties; hence the interest in the analysis of these compounds in all environmental media, including biota. The increasing prevalence of PFASs in the environment, including remote polar areas, has been reported and is of growing concern. Seabirds are top predators, generally long-lived, which are particularly at risk considering the biomagnification properties of some PFASs. Thus, they constitute relevant sentinel organisms to investigate the occurrence and effects of PFASs in both the Arctic and the Antarctic. The aim of this work was to develop a robust, sensitive and rapid analytical procedure to determine 23 legacy and emerging PFASs in Antarctic seabird plasma. The method was based on minimal sample pretreatment along with on-line solid phase extraction (SPE) coupled to liquid chromatography and tandem mass spectrometry (LC-MS/MS), with a small amount of plasma sample (25 µL). 13 mass-labelled internal standards were gravimetrically added at the beginning of the procedure, compensating for potential recovery losses and matrix effects. Sample preparation consisted in protein

precipitation with acetonitrile, followed by centrifugation, filtration of extracts, and dilution with HPLC-grade water. Method optimization was conducted with the use of experimental designs and included study of the protein precipitation solvent, influence of pH, nature of the on-line SPE cartridge, on-line SPE loading flow rate and loading volume. The method was validated by assessing instrumental and method detection limits, linearity range, as well as precision, recovery, accuracy and matrix effects on fortified chicken plasma. Environmentally relevant limits of detection were reported (0.0001–0.13 ng.g<sup>-1</sup>) and 17/23 out of the 23 target analytes, 17 showed excellent accuracies ( $\pm 20\%$ ). The analysis of a human serum certified reference material (NIST SRM 1957) was also included to evaluate method accuracy. The optimized method was subsequently applied to a selection of Antarctic seabird species, 11/23 targeted analytes being detected ( $\Sigma$ PFASs range: 0.4–19.1 ng.g<sup>-1</sup>). The reduced plasma sample size required (25  $\mu$ L) implies that this method could also be applied to the analysis of PFASs in small bird and fish species.

## Challenges in Wastewater Treatment and Reuse and the Agricultural Use of Manures and Biosolids (I)

### Implementation of the Swiss water protection act: results from the first mover with advanced wastewater treatment

C.S. McArdell, Eawag / Department of Environmental Chemistry; M. Boehler, Eawag / Department of Process Engineering; E. Borowska, Silesian University of Technology / Departement of Environmental Biotechnology; M. Bourgin, Eawag Swiss Federal Institute of Aquatic Science and Technology; J. Fleiner, Eawag / Process Engineering; J. Hollender, Eawag / Environmental Chemistry; C. Kienle; R. Teichler, Eawag / Environmental Chemistry; A. Wittmer, Process Engineering Swiss Federal Institute of Aquatic Science and Technology EAWAG; H. Siegrist, Eawag / Process Engineering

In March 2014, the new Swiss water protection act was accepted by the federal and national councils of Switzerland, and its implementation is planned for 2016. It was decided that measures will be taken at the municipal wastewater treatment plants to reduce the load of micropollutants entering the aquatic environment from the plants by about half. To reach this aim, about 100 out of the 700 Swiss wastewater treatment plants (WWTPs) will need to be upgraded with advanced treatment. The technologies proposed are ozonation or treatment with powdered activated carbon. The effectiveness of the measure should be evaluated by measurements of a set of substances which need to be eliminated by 80%. The Neugut plant in Dübendorf is the first WWTP in Switzerland where a full-scale advanced treatment of wastewater with ozone has been installed and is running since March 2014. Eawag supported the installation of the plant scientifically and several investigations are currently running on the plant. The effectiveness of the treatment technology is assessed for chemical and for ecotoxicological quality control, and the production of transformation products formed in ozonation is investigated. Moreover, appropriate control and operation strategies are studied. Within this presentation, background information will be given on the new Swiss water protection act and results of the investigations at WWTP Neugut are shown.

### Preparing for Phase 2 of the Chemical Investigations Programme in England and Wales

V. Jones; M. Gardner, Atkins Ltd; B. Ellor, UKWIR

The treatment and removal of trace substances from wastewater represents a significant challenge. In response to this challenge, a large monitoring programme was set up collaboratively by water companies in the UK - the Chemical Investigations Programme (CIP). Upon completion of CIP in 2013, it became clear that additional investigations were necessary. The CIP Phase 2 (CIP2) will focus on site-specific issues in England and Wales and the development of novel technologies to address these. This paper describes the complex process of scoping the scale and extent of this significant programme, including the establishment of effective communication channels between the project stakeholders, determining the overall objectives of the work, prioritising the substances of concern and designing the sampling. Approximately 600 wastewater treatment works (WwTWs) where sampling will take place were identified. Influent, effluent, sludge and in-river samples will be collected. The analytical suite includes metals, priority substances, sanitary determinands, steroids, and pharmaceuticals. A key output of the scoping phase was the development of bespoke data processing tools, with an emphasis on effective graphical presentation of the results, accessible to the non-specialist. With the scoping now complete, CIP2 sampling is set to commence in 2015. This ambitious programme will aim to help the UK fulfil its obligations with regards to the Water Framework Directive and provide results of global importance on the sources and treatment of trace contaminants in wastewater and rivers.

### Grand Designs for Wastewater Recycling in Antarctica - Challenge of Micro-contaminant Assessment

M. Allinson, The University of Melbourne / School of Chemistry; K. Kadokami, The University of Kitakyushu; D. Nakajima, National Institute for Environmental

Studies; P. Scales, The University of Melbourne; G. Allinson, RMIT University / CAPIM; A. Knight, The University of Melbourne; J. Zhang, Victoria University; M. Packer, Australian Antarctic Division; K. Northcott, Veolia; V.J. Pettigrove, The University of Melbourne / Zoology; S. Gray, Victoria University  
The Australian Antarctic Division (AAD) operates Australia's Davis Station in the Antarctic. In 2005, Davis Station's wastewater treatment plant failed, and since then untreated, macerated effluent has been discharged to the ocean. Although disposal of the station's effluent by this method meets the minimum requirements specified by international agreements, an environmental impact assessment has identified that there is a clear need for enhanced sewage treatment. A new advanced treatment plant that is small enough to fit inside two shipping containers has been designed and built by Victoria University, the University of Melbourne, the Australian Antarctic Division, Veolia Water and AECOM, and supported by the Australian Water Recycling Centre of Excellence, to provide the enhanced sewage treatment. In the plant, secondary treated wastewater will undergo a multi-barrier process involving ozonation, ceramic microfiltration, biologically activated carbon filtration, reverse osmosis, ultraviolet disinfection and chlorination to remove trace organic contaminants and pathogens. This project will collect samples at each of stage in the multi-barrier process, and use integrative bioassay methods (yeast-based recombinant receptor reporter gene bioassay) to assess the performance of each of those barriers in removing organic chemicals of similar receptor binding properties and to assess the quality of the brine concentrate for disposal. To cost-effectively screen the widest possible range of micro-pollutants, the project will use the AIQS (Automated Identification and Quantification System) database GC-MS and LC-TOF-MS screening system (methods that can determine more than 1200 organic chemicals). Once the performance of the system has been verified, the plant will be shipped to Antarctica and installed alongside a new secondary treatment plant. The combination of the two treatment plants will convert the station's effluent into some of the cleanest water in the world which, when discharged to the ocean, is expected to have minimal impact on the local marine environment.

421

### Fate of pharmaceuticals from wastewater treatment plant effluents in ozonation and biofiltration processes

C. Zwiener, Environmental Analytical Chemistry, Center for Applied Geoscience, University of Tuebingen / Geosciences; S. Merel, French School of Public Health / LERES

Many pharmaceutical active compounds are continuously introduced into the aqueous environment mainly from effluents of wastewater treatment plants (WWTP) and sewer overflows and therefore affect water quality and potentially impact ecosystems and human health via drinking water supply. Therefore further treatment processes for WWTP are considered to remove pharmaceuticals and other contaminants from effluents. Ozonation revealed as one of the most promising processes. However, ozonation is also known to produce transformation products which are largely unknown and raise concern regarding their potential impact on ecosystems and human health. In this work we will show the application of target and non-target screening with LC-electrospray ionization-quadrupole-time-of-flight-mass spectrometry (LC-ESI-Q-TOF-MS) combined with computer based data evaluation with statistical data analysis and tools of computational mass spectrometry to elucidate the removal of original contaminants and the occurrence of transformation products during ozonation and biofiltration as post-treatment processes of WWTP effluents. More than 6500 compounds have been detected in the samples like metoprolol, carbamazepine, diclofenac, bezafibrate, tramadol, as well as some metabolites like valsartan acid, carbamazepine epoxide, hydroxy and oxycarbamazepine and the metazolol metabolites aminoantipyrine, formylaminoantipyrine and acetamidoantipyrine. The effects of ozonation and biofiltration on these compounds have been visualized by cluster and similarity analysis. The results show the removal of almost 1100 compounds like bezafibrate, carbamazepine or tramadol, but also the formation of 600 compounds during ozonation and their persistence during biofiltration. Among the formed transformation products are tramadol-N-oxide and the carbamazepine ozonation product BQM (1-(2-benzene-aldehyde)-4-hydro-(1*H*,3*H*)-quinazoline-2-one), which revealed persistent in subsequent biofiltration. This illustrates the necessity for the identification of further transformation products and the consideration of potential toxic effects for a further assessment of such treatment processes.

422

### Preparation of antimicrobial membranes from electrospun fibers containing metal-organic frameworks

R. Rosal, Ingenieria Quimica; J. Quiros, Universidad Alcalá de Henares / Chemical Engineer; K. Boltes, University of Alcalá / Chemical Engineering; S. Aguado, University of Alcalá; R. Guzman de Villoria, IMDEA Materials; J. Vilatela, Instituto IMDEA Materiales

A new class of polylactic acid (PLA) composite fibers containing cobalt-based metal organic frameworks (MOF) is presented. The MOF used was Co-SIM-1, a cobalt-based substituted imidazolate, which provides a controlled release of cobalt to the fiber environment. Composite mats were prepared by electrospinning PLA with a suspension of polyvinylpyrrolidone-stabilized Co-SIM-1. MOF particles formed aggregates of a small number of primary particles that, after electrospun,

became completely embedded inside polymeric fibers. The particle dispersion was better for lower loadings, for which the relative amount of metal released to culture media was also higher. The microorganisms used in this study were *Pseudomonas putida* and *Staphylococcus aureus*. The antimicrobial activity of composite mats was assessed using SEM images, fluorescence microscopy, direct plate reading of fluorescent stains and plate count of colony forming units, among other. SEM images showed that for increasing concentrations of Co-SIM-1, the fibers became less susceptible to bacterial colonization and biofilm formation. Confocal microscopy and quantitative tests for microbial growth assessment confirmed this observation. A device for plate reading on the surface of a whole 59 mm mat was used, which allowed quantifying fluorescent stains on the surface of electrospun mats. Fluorescent stains were used for the simultaneous identification of viable and non-viable cells. The results showed an increase in non-viable cells for 6 wt. % Co-SIM-1 mats of up to 40 % for *P. putida*, with a parallel decrease in viable microorganisms. The effect was higher for *P. putida* than *S. aureus*, an effect that could be associated with the different way of transporting cobalt in gram-negative and gram-positive bacteria. The comparison between the amount of viable cells (FDA staining) and the number of CFU for cultures of *P. putida* and *S. aureus* showed a higher sensitivity of *P. putida* to the inclusion of cobalt in fibers with a reduction in the number of viable cells reaching 40% with respect to neat PLA mats. The results also showed higher relative FDA values with respect to colony counting, which could be interpreted as a result of the existence of viable but non-culturable microorganisms associated to the inclusion of cobalt into fibers. Cobalt-based MOF included in electrospun mats provide antibacterial activity suitable to be used to prepare membranes or other fiber-based materials with antimicrobial functionality.

##### **Inactivation of antibiotic resistant bacteria in urban wastewater by solar advanced oxidation processes**

A. Fiorentino, University of Salerno / Civil Engineering; G. Ferro, Civil Engineering; M. Castro Alferez, M. Polo-López, Plataforma Solar de Almería-CIEMAT; P. Fernández-Ibáñez, Plataforma Solar de Almería-CIEMAT; L. Rizzo, University of Salerno / Civil Engineering  
In the present work solar disinfection and solar driven advanced oxidation processes (AOPs) were evaluated in the inactivation of indigenous antibiotic resistant bacteria (ARB) in real urban wastewater.  $\text{H}_2\text{O}_2$ /Sunlight,  $\text{TiO}_2$ /Sunlight,  $\text{H}_2\text{O}_2$ / $\text{TiO}_2$ /Sunlight and natural photo-Fenton (wastewater pH unchanged) were the AOPs investigated. A multidrug (namely ampicillin, ciprofloxacin and tetracycline) resistant *E. coli* strain isolated from the effluent of the biological process of an urban wastewater treatment plant (UWTP) was the target ARB. The best disinfection efficiency was observed for  $\text{H}_2\text{O}_2$ / $\text{TiO}_2$ /Sunlight process with inactivation of the *E. coli* strain under the detection limit ( $2 \text{ CFU mL}^{-1}$ ) achieved for  $3\text{--}5 \text{ KJ L}^{-1}$  ( $Q_{UV}$ ), depending on  $\text{H}_2\text{O}_2$ / $\text{TiO}_2$  ratio. A good performance was observed with  $\text{H}_2\text{O}_2$ /Sunlight process was observed with inactivation of the *E. coli* achieved for  $8 \text{ KJ L}^{-1}$  ( $Q_{UV}$ ). While with the  $\text{Fe}^{2+}$ : $\text{H}_2\text{O}_2$ , at natural pH, the best performance of inactivation was reached with  $15 \text{ KJ L}^{-1}$ . Photo-Fenton was also effective in the inactivation of the target microorganism (DL achieved for  $\text{Fe}^{2+}$ : $\text{H}_2\text{O}_2$ =5:10 ratio at  $15 \text{ KJ L}^{-1}$ ) and it was comparable to  $\text{H}_2\text{O}_2$ /Sunlight process ( $20 \text{ mg L}^{-1}$  of  $\text{H}_2\text{O}_2$ ,  $Q_{UV}$ = $18 \text{ KJ L}^{-1}$ ), possibly due to dissolved iron precipitation at natural wastewater pH. Antibiotic resistance versus AMP ( $10 \text{ } \mu\text{g}$ ), CIP ( $5 \text{ } \mu\text{g}$ ), cefuroxime (CXM,  $30 \text{ } \mu\text{g}$ ), nitrofurantoin (NI,  $100 \text{ } \mu\text{g}$ ) was tested. All investigated processes did not affect antibiotic resistance of survived colonies. **Keywords:** antibiotic resistance, photo Fenton,  $\text{TiO}_2$  photocatalysis

## **Managing nanomaterials in the environment: lessons learnt to date, state of the art and future perspectives (I)**

#### 424

##### **A decision tree model to determine the difference between engineered and natural nanomaterials**

S. Wagner, University of Vienna / Department of Environmental Geoscience; A. Gondikas, E. Neubauer, University of Vienna / Environmental Geosciences; T. Hofmann, University of Vienna / Department of Environmental Geosciences; F. Von der Kammer, Vienna University / Department of Environmental Geosciences  
There is no doubt that the development of nanotechnology leads to the emission of engineered nanomaterials (ENMs) into the environment. The ongoing discussion on the assessment of this release is mainly concern-driven because NMs exposure may have adverse effects on the ecosystem and biota. In order to quantify this risk, information on the fate and behavior of ENMs is required and it is also critical to determine whether these new materials are significantly different than their natural counterparts. Similar processes have been studied for decades for naturally occurring nanoparticulate ( $1\text{--}100 \text{ nm}$ ) and colloidal ( $1\text{--}1000 \text{ nm}$ ) substances. The knowledge gained from these investigations is nowhere near sufficiently complete to create a detailed model of the behavior and fate of ENMs in the environment, but is a valuable starting point for the risk assessment of these novel materials. Therefore, the comparison of naturally observed processes with those studied for engineered systems may help to identify the "nano-specific" properties of ENMs. From the state-of-the-art knowledge, we developed a decision tree model for determining whether engineered nanomaterials differ from their natural

counterparts in terms of environmental fate. The model is built on three processes that are critical for the fate and behavior of engineered and natural nanomaterials in the aqueous environment: (I) surface modifications, (II) particle colloidal stability and transport, and (III) dissolution. It is based on a literature search focusing on recent publications (after 2010). Literature data indicates clearly that persistent organic coatings and core-shell structures differentiate ENMs from their natural counterparts through their surface transformations. In cases where there is evidence of a distinct behavior, the model provides suggestions for laboratory tests which are required to determine the fate and behavior of the specific ENM. Our approach can be considered as a contribution towards a process oriented risk assessment of nanomaterials which links existing knowledge on fate and behavior of natural colloids and engineered nanomaterials.

#### 425

##### **Repeated exposure - Effects of two nanomaterials on soil microorganisms**

K. Schlich, Fraunhofer IME - Institute for Molecular Biology and Applied Ecology; L. Beule, Fraunhofer IME; K. Hund-Rinke, Fraunhofer IME  
Nanomaterials (NM) enter the environment by different pathways. A repeated exposure of NM via sludge by multiple applications onto soil over years would be a realistic scenario. The aim of our study was to investigate the effects of CuO-NMs (Plasmachem GmbH) and AgNMs on soil microorganisms with the main focus on a repeated exposure scenario. At the single application  $1.67$  and  $5.0 \text{ mg/kg}$  soil for AgNM and  $333$  and  $1000 \text{ mg/kg}$  for CuO-NM were applied at test start. For the repeated exposure we used  $0.56$  and  $1.67 \text{ mg/kg}$  for AgNM and  $111$  and  $333 \text{ mg/kg}$  for CuO-NM. Here, the NMs were applied at day 0/28/56. Three test systems were used to assess the effect on the soil microorganisms: ammonium oxidation (ISO Guideline 15685), enzymatic activity patterns (ISO 22939) and MicroResp approach. Ammonium oxidizing bacteria were sensitive towards AgNM after 28 and 56 days of exposure independent of the application, whereas CuO-NM resulted only at high concentrations in an inhibition. For AgNM we found that, mainly the N-transformation was affected, observing the enzymatic activity patterns. Additionally, the C- and P-transformation was slightly affected at both the highest test concentration with single application and repeated exposure after 56 days. Applying the MicroResp approach, a more intense inhibition of the substrate induced respiration was observed. After 56 days we found that all transformations (C, N, P) were significantly inhibited at both the highest test concentration with single application and repeated exposure. Comparable results were observed for CuO-NM with a higher sensitivity of the N- and P- transformations compared to the C-transformations after 28 days. Currently, a repeated exposure resulting finally in the same test concentrations as a single application does not provide further information. The results of the study reveal that a lower solubility and a concomitantly lower ion release lead to a lower toxicity. The test duration is an important factor and should be extended to observe a slow long-term ion release. Tests for functional diversity reveal that using comparable carbon sources the test systems have a different sensitivity. Due to the measuring principle in both test systems different enzymes (exo-/endoenzymes) are addressed. The two test systems together provide a tool representing an early warning system for possible damages to the soil microorganisms. Acknowledgement - The study was funded by the EU FP 7 MARINA and SUN.

##### **Establishment of AgNPs toxicity profiles and uptake routes in earthworms (E. fetida) combining Standard Toxicity Tests (OECD-207, 222) and coelomocyte biomarkers**

N. Garcia, UPVEHU / Department of Zoology and Animal Cell Biology; M. Gandariasbeitia, E. Urionabarrenetxea, University of the Basque Country UPV-EHU; A. Irizar Loibide, Aarhus University (AU) / Department of Bioscience; M. Soto, University of Basque Country / Zoology and Animal Cell Biology  
Research Centre for Experimental Marine Biology and Biotechnology  
PIEUPVEHU

Silver nanoparticles (AgNPs) are extensively used in consumer products mainly due to their antimicrobial properties. AgNPs enter the terrestrial environment, though the land disposal of sewage sludge (wastewater treatment plant), or incineration and posterior deposition, and could modify the soil community structure and functions. However, little is known about the hazards of nanosilver in soils (either dissolved in pore water or coupled to soil organic matter) and their effects on soil organisms. Earthworms have been widely used for soil health assessment due to their pivotal role in the soil and their quick and measurable responses after exposures to pollutants. Soil health can be assessed measuring these responses (biomarkers) in their immune cells (coelomocytes) and with the aid of standardized toxicity tests. The aims of this work were (a) to determine the toxicity profile of AgNPs combining Standard Toxicity Tests (OECD-207 and 222) with cell-level biomarkers (Neutral Red Uptake -NRU- and Calcein-AM Viability assays), and (b) to determine the uptake routes (dissolved, ingested) of AgNPs for a correct assessment of soil toxicity using *Eisenia fetida* earthworms. Earthworms were exposed to a range of concentrations of PVP-PEI coated AgNPs. Then Earthworm Acute Toxicity test (OECD-207), including a Paper Contact toxicity test and Artificial Soil tests at short (3 d) and medium (14 d) terms, and the Earthworm Reproduction Test (OECD-222) were applied. The viability of coelomocytes was assessed by NRU and Calcein-AM tests. Autometallography and Alcian Blue were used to address Ag distribution and morphological alterations in

the digestive tract and in the epidermis. Paper Contact test revealed a LC50 of 346.5 ppm Ag-NP and Artificial Soil test of 144.2 mg Ag-NP/kg. Histological and histochemical analyses proved that the primary uptake of AgNPs was via soil ingestion. A decrease in the number of viable cells occurred after 3 d of exposure to 50 mg Ag-NP/kg and after 14 d to 5 mg Ag-NP/kg. Reproduction was severely impaired at high Ag-NP doses. In conclusion, the combination of Standard Toxicity Tests and coelomocyte biomarkers was useful to establish AgNPs toxicity thresholds and to determine their uptake route by earthworms. This approach can be used for assessing the potential risks of AgNPs in soils. Acknowledgements: Basque Government (Grant to Cons. Res. Groups; IT810-13), Univ. Basque Country (UFI 11/37) and Spanish MINECO (Nanosilveromics Project).

##### **Plants matter - Barriers, pathways and processes for uptake, translocation, and accumulation of nanomaterials in plants**

F. Schwab, Duke University / Civil Environmental Engineering CEINT; G. Zhai, M. Kern, The University of Iowa / Civil Environmental Engineering; A. Turner, Duke University; J.L. Schnoor, The University of Iowa / Civil Environmental Engineering; M. Wiesner, Duke University  
Uptake, transport and toxicity of engineered nanomaterials (ENMs) into plant cells are complex processes that are currently still not well understood. Parts of this problem are the multifaceted plant anatomy, and analytical challenges to visualize and quantify ENMs in plants. Especially higher plants are the base of many food webs and paramount for human nutrition. To assess the toxicity, the exposure, and eventually, the risk of ENMs for human health and the environment, comprehensive knowledge on the uptake and transport processes of ENMs in plants is needed. Numerous recent studies have documented ENM uptake into plants either by dissolution of the ENMs, or by uptake of particulate matter through the apoplast. Still, the physiological features of plants favoring ENM uptake into the plants remain unknown, making it impossible to identify the most ENM-affected plant species or exposure pathways [1]. We will present a detailed critical review on the uptake, translocation, and accumulation of ENMs in plants, taking into account plant physiology and the physico-chemical properties of all relevant uptake barriers of higher and lower plants. Further, for the first time, based on the knowledge gained from plant uptake studies over the last ten years, an uptake model for ENMs will be proposed and shown to be valid for studies of uptake experiments performed under environmentally relevant conditions. Finally, the most important knowledge gaps will be analyzed. As a whole, the findings of the approximately 200 original studies performed during the last ten years on ENM translocation in plants show that the plant cell wall, long considered as an almost impassable barrier for ENMs, is much more permeable than previously assumed. The lack of observed toxicity may therefore not be caused by a lack of uptake, but by the presence of defense reactions of the plants that effectively cope with ENMs. The next steps towards producing a realistic risk assessment of nanoparticles in plants are to measure ENM uptake rates, the size exclusion limit of the apoplast, and to unravel plant physiological features favoring uptake. [1] Dietz KJ, Herth S. 2011. Plant nanotoxicology. *Trends in Plant Science* 16:582-589. [2] Schwab F, Zhai G, Kern M, Turner A, Schnoor JL, Wiesner, MR. Barriers, Pathways and Processes for Uptake, Translocation, and Accumulation of Nanomaterials in Plants—Critical Review. Submitted to *Nanotoxicology*.

##### **Quantity and quality of natural organic matter trigger the ecotoxicity of titanium dioxide nanoparticles to *Daphnia magna***

F. Seitz, Inst. for Environmental Sciences / Institute for Environmental Sciences; R.R. Rosenfeldt, University of Koblenz-Landau, Institute for Environmental Sciences / Institute for Environmental Sciences; M. Müller, R. Schulz, University of Koblenz-Landau / Institute for Environmental Sciences; M. Bundschuh, Department of Aquatic Sciences and Assessment Swedish University of Agricultural Sciences / Department of Aquatic Sciences and Assessment  
The heavy production and use of engineered nanoparticles likely leads to their unintentional release into aquatic ecosystems. There nanoparticles underlie a distinct fate, which is amongst others determined by the amount and properties of natural organic matter (NOM) ultimately modifying the nanoparticles' ecotoxicological potential. However, little is known about the underlying mechanisms, particularly which NOM properties (=quality) trigger such shifts. Therefore, the present study targeted the question how NOM quantity and quality alter the ecotoxicological potential of titanium dioxide nanoparticles (nTiO<sub>2</sub>) towards the water flea *Daphnia magna*. For this reason two nTiO<sub>2</sub> products (A-100 and P25; ~100 nm), were investigated in combination with four NOMs of different quality at four levels of total organic carbon each (0.00, 0.04, 0.40, 4.00 mg/L). The results showed, that – independent of the applied nTiO<sub>2</sub> product and NOM type – nTiO<sub>2</sub> toxicity decreased by a factor >6 at higher NOM concentrations when compared to an exposure scenario without NOM. Further, besides the quantity also the quality of NOM seems to trigger the reduction in nTiO<sub>2</sub> induced toxicity: Both the aromaticity and hydrophobicity of NOM correlated positively with the EC<sub>50</sub> values of both nTiO<sub>2</sub> products. These data suggest a rather low ecotoxicological risk of nTiO<sub>2</sub> in natural aquatic environments as its ecotoxicity is reduced in the presence of any NOM tested here. However, interactions of nTiO<sub>2</sub> and NOM under various conditions such as further environmental and/or chemical stressors need to be understood to reliably predict the environmental risks of such nanoparticles.

#### 429

##### **The effect of silver nanoparticles on a freshwater alga (*Pseudokirchneriella subcapitata*) under three different test designs**

J. Curry, Heriot Watt University / Life Sciences; J. Kinross, Heriot-Watt University / School of Life Sciences; H. Johnston, Heriot Watt University / Life Sciences; T.F. Fernandes, Heriot-Watt University / School of Life Sciences

*Pseudokirchneriella subcapitata* is a freshwater alga frequently used in standard toxicity tests; a primary producer with high ecological relevancy. Project work done to date has focussed on silver nanoparticle toxicity, due to its frequent occurrence in consumer products. JRCNM03002a (formerly NM300K) was used as a reference; an aqueous dispersion of silver nanoparticles of a modal size of 15 nm, provided by the European Commission Joint Research Centre. Silver nitrate was used to compare the effects of silver ions to their nanoparticulate form. Acute hazard studies allowed the derivation of EC50 values based on growth inhibition (OECD 201 Freshwater Alga and Cyanobacteria, Growth Inhibition Test). These were compared across 3 experimental designs – flasks, 24 well plates, and 96 well plates. Humic acid, pH and medium composition were also investigated. Preliminary results suggest test sensitivity is dependent on media choice, while variability is dependent on experimental approach. Growth inhibition tests have shown higher toxicity in a non-standard medium, compared to standard OECD medium. Growth inhibition decreased with exposure time (up to 72 hours) in all tests, for both ionic and nanoparticulate silver. This may be due to loss of toxicant to the test system, or the onset of tolerance in *P. subcapitata*, and requires further investigation. Standard toxicity tests offer a degree of flexibility in terms of test design, media, or target species. These results highlight the need for consideration of standard test deviations when comparing EC50s between laboratories. Small volumes and high replication may offer a robust approach of screening many toxicants in parallel, but care must be taken when comparing results between different methods. As this work has been carried out with silver nanomaterials, consideration must be made when extrapolating these results to other nanomaterials. Future work includes non-standard methods, including short term photo-inhibition tests and sub-lethal bioassays. Cellular stains employed in mammalian toxicology will be investigated for their applicability to *P. subcapitata*. Such methods may be of practical utility to regulators due to higher replication and ease of sampling, compared to existing standard tests. Funding for this project was provided by the European Commission FP7 project MARINA (Managing the Risks of Nanomaterials), which seeks to develop and validate risk management methods for nanomaterials.\n

##### **Prospective Life Cycle Thinking approaches for the definition and implementation of sustainability strategies in industry and policy making (I)**

#### 430

##### **Product Environmental Footprint pilot phase - will it lead us to a harmonized life cycle based approach usable for comparative assertion?**

V.K. Bach, Technische Universität Berlin; A. Lehmann, Technische Universität Berlin / Department of Environmental Engineering Chair of Sustainable Engineering; M. Finkbeiner, DaimlerChrysler AG / Chair of Sustainable Engineering

The Product Environmental Footprint methodology (PEF) published in 2013 by the European Commission aims at harmonising existing methods, while decreasing the flexibility provided by ISO standards regarding methodological choices. Currently the method is tested for 25 pilots, which develop PEF specific product category rules (PEFCR). These rules will set the basis for comparative assertions, which is one of the goals of the European Commission. A detailed analysis of the pilots was carried out to evaluate the applicability of the PEF methodology as well as to assess, if the developed category rules can serve as future basis for comparative assertions based on benchmarks and performance classes. The analysis revealed several challenges related to the implementation of specific methodological PEF requirements. For example, none of the pilots use the required 2 or 3 digit CPA/NACE codes, but apply 4 to 6 digit codes instead. The CPA/NACE code system, which was originally intended to support comparability, appears to be used as a “folder system” instead of a “classification system”. Moreover, within some pilots the unit of analysis does not specify the “quality” of the product sufficiently, which is relevant for potential future PEF labelling schemes. Ensuring that all products covered in one product category provide the same functionality is essential for comparative assertion. Furthermore, different approaches for defining the representative product are used e.g. based on economic and physical market shares. Thus, depending on the chosen approach, the resulting “representative” environmental impacts can differ. Further challenges and inconsistencies identified refer to defining system boundaries. Also, to guarantee a real comparability of products, all processes influenced by the product need to be adapted according to the different product composition.. In addition fixing of secondary data leads to reproducibility, but not to a fair comparability as “greener” materials cannot be taken into account. The analysis revealed several challenges and inconsistencies within the developed drafts many of them appear to be contra productive for the development of comparability scheme. The evaluation is based on the first drafts of the first wave but the second wave of pilots will be addressed in the presentation as

#### 431

##### **Global Principles and Practices for Hotspots Analysis**

M. Barthel, WRAP / Food Sustainability; C. Harmanan, J.A. Fava, PE INTERNATIONAL, Inc.; P. Strothmann, UNEPSetac Life Cycle Initiative  
A growing number of different analytical disciplines are using a prioritisation method called 'hotspotting' or 'hotspots analysis'. It is being used to filter and distil often large volumes of information to identify and prioritise hotspots for further investigation or action by industry, governments and other stakeholders. Hotspots analysis is increasingly being used to address significant sustainability challenges, like unsustainable levels of resource use and waste; water scarcity and improved river catchment management; product sustainability and the setting of sectoral sustainability strategies; by helping to provide focus in an era of information overload. Currently no common global approach to hotspots analysis exists; nor has there been any effort to bring together or share best practice amongst those product sustainability initiatives currently involved in hotspots analysis. Neither do any accepted principles or guidance exist on how to translate and apply the results of this analysis into meaningful sustainability information for use by industry, governments and other stakeholders. To address these gaps, this research project aims to: Develop a common understanding of and map hotspots analysis approaches currently in use around the world, their application at different scales or levels of detail (e.g. how they can be applied at a national, sector and product category-level); and to share the learning and experiences derived from these existing approaches; Develop, agree and pilot a commonly-agreed methodological framework and global guidance for 'hotspots' analysis based on identified principles and best practices, as a means of accelerating and prioritising international action on key sustainability issues; To develop and agree a guidance document on the consistent and appropriate use of the sustainability information derived from hotspots analysis; Evaluate and, if possible, implement a range of options to bring together the findings from existing hotspots studies to create a shared knowledge base that is able to provide a richer, global picture of sustainability hotspots in the economy and society; and the range of options or solutions available to address them. The presentation will provide an overview of the results of the mapping study that has recently been conducted. It will also provide initial insights into how a methodological framework could look like, drawing on the results of the mapping study.

##### **LCA deployment in legislation - description of policy options for the example of CO2 legislation in automotive industry**

A. Lehmann, Technische Universität Berlin / Department of Environmental Engineering Chair of Sustainable Engineering; M. Finkbeiner, DaimlerChrysler AG / Chair of Sustainable Engineering  
Life Cycle (LC) Thinking is on the political agenda and many industries are actively developing LCA approaches since many years. As, we think that it is in substance "right" to base environmental legislation on LCA, we started to explore and develop policy for integrating Life Cycle Assessment (LCA) into legislation. This research process included identification and prioritization of various policy options, analysis of technical requirements, SWOT-/ RACER analysis and the development of scenarios for policy implementation. It was found that theoretically a broad range of options for implementing LCA into policies exists (e.g. mandatory or voluntary options, process- or performance based options) and that practically some of them are already implemented in European legislation. For four selected policy options, a deeper analysis was conducted; technical requirements (e.g. methodology, models, data) as well as strengths, weaknesses or acceptance from different stakeholder perspectives were described and implementation scenarios were developed. It was found, that some technical requirements are the same for both voluntary and mandatory policies and that sometimes, voluntary policy has strictest requirements. Moreover, it was shown that generally highest relevance regarding CO<sub>2</sub> reduction, but also highest efforts for implementation seem to be related to the mandatory-performance-direct option. Moreover, it was shown, that robustness and credibility can principally be guaranteed by all policy options and that acceptance strongly depends on the perspective of the stakeholder groups. Findings from stakeholder meetings (policy makers and OEMs) conducted in the EU and beyond (in Japan, the US and China) complemented these results. In the first phase of the study promising policy options were identified without having indicated a clear analytical, scientific overall preference for one single policy option. It was shown that technical implementation strongly depends on the implementation level and that solutions for most technical requirements are already available, but that a consensus on proper setting of these requirements is missing. The research process will be continued, including a broader stakeholder dialogue in Europe, the US, Japan and China to communicate and refine the policy options as well as to specify possible implementation pathways for LCA deployment in legislation.

##### **Economic value as a functional unit for environmental labelling**

H.M. van der Werf, INRA, UMR SAS / Environnement et Agronomie; T. SALOU, INRA, UMR SAS / Environnement et Agronomie  
Sustainable development has become a major component of French public action.

A law was passed on environmental labelling of products, to be based on a product's life cycle. To implement this law a trial has been conducted, involving 168 companies. The French parliament produced a report, based on this trial, on the interest of environmental labelling. Regarding food, the report criticizes the functional units (FU) chosen: 100 g, 100 ml, as they do not reflect the functions of food. These FU will favour high-input intensive systems and result in higher impacts for products from low-input and organic systems aiming to produce quality products. This paper is a contribution to the debate on environmental labelling as a strategy to promote sustainability. We present our thoughts and a proposition on the most appropriate FU for environmental labelling of food and other consumer products. In order to illustrate our proposition we present a case study that explores the effect of the choice of FU on the ranking of agricultural products from production systems of contrasting intensification level (i.e. conventional versus organic agriculture). When using the FU live weight, organic animals had larger impact values than conventional animals. Per ha of land, organic animals had smaller impacts than conventional animals. Organic agriculture thus constitutes a less impacting mode of land use. When the FU economic value is used, organic animals have similar or lower values for eutrophication, lower values for climate change and higher or similar values for land occupation. The choice of FU is crucial. The FU economic value is attractive, as it considers product quality through the product's price. The price difference between organic and conventional animals reflects a willingness of consumers to pay more for a product that is perceived to be of better quality. There often is a tradeoff between quantity and quality. A mass-based FU tends to favour products from systems that focus on quantity rather than quality. An economic-value-based FU will be more favourable to systems producing quality products. More generally, an economic-value-based FU is very well suited for environmental labelling of any type of consumer product, it allows the integration of positive rebound effects: consumers that purchase more expensive quality products will have less income available for other consumption. **The views expressed here are those of the authors and should not be attributed to INRA.**

#### 434

##### **GREENING BOOKS Sustainability strategy for the Publishing Sector**

M. Escamilla, LEITAT / Sustainability Unit; C. Hidalgo, G. Ferrer, LeitAT Technological Center / RD Safety Sustainability Division; J. Panyella, El Tinter  
**GREENING BOOKS** is an innovative strategy for the Publishing industry comprising scientific work, online tools and guidelines for industry and stakeholders involvement to tackle the environmental aspects of the sector throughout EcoPublishing. EcoPublishing is an innovative form of publishing, incorporating environmental criteria in the publication's supply chain processes that minimize the negative impact during all its phases. To assure rigorous scientific basis, the first step was to carry out a comprehensive LCA for two types of publications (a book and a magazine) in order to quantify their potential environmental impact and to identify the contribution of each stage involved in the system studied: design, raw materials, offset printing, finishing, packaging, distribution and end-of-use. Based on LCA methodology and results, an online simplified tool *BookDAPer* was developed. It easily calculates the environmental footprint of publications, obtaining indicators such as energy, water and raw materials consumption, waste generated or CO<sub>2</sub>eq emitted during all the life cycle. The environmental information created through the tool automatically elaborates a simplified Ecolabel inspired in Environmental Product Declaration. The new ecolabel can be inserted in the publication providing qualitative information (i.e. paper certificates, environmental certificates of companies involved in printing, designing, etc.) and quantitative information (e.g. indicators and potential environmental savings) to the readers. The tool users do not need to be experts on LCA since the software has the main characteristics of publications, which they perfectly know, as inputs. Moreover, the results of the LCA have also been the basis to elaborate a *Good practices Guideline for ecodesign on the publishing sector* meant to provide a practical appliance to professionals such as designers, printers and publishers to improve their environmental behavior and to communicate the results to readers in an efficient and user-friendly way. The strategy was led by a technological center, a printing house and an eco-innovation company, in close cooperation with industry experts and relevant decision makers, which have allowed obtaining primary data for the LCA inventory and industry consensus when deciding tool functionalities and bDAP content. The pilot experiences conducted by SMEs had been of key importance to monitor and improve this sustainable business strategy.

#### 435

##### **Making a Difference: incorporating embodied impacts into the decision-making processes of key actors in the construction and property industry**

M. Balouktsi, Karlsruhe Institute of Technology (KIT) / Chair of Sustainable Management of Housing and Real Estate; T.P. Lützkendorf, KIT Karlsruhe Institute of Technology / Economics Business Engineering; G. Foliente, CSIRO Land and Water

A major wave of initiatives with respect to implementation of sustainable development principles in the mainstream construction and property sector have led in recent years to the development and application of new design methods and tools, innovative products and technologies, national and international standards, as well

as numerous systems for describing and certifying the sustainability of buildings. Primarily, these efforts were focused on reducing the negative environmental impacts of the operation of buildings. But as the building efficiency increases, embodied impacts associated with the production, maintenance, and eventual end of life of buildings become more significant. This is a good reason for the key actors in the construction and property industry to intensify the discussion on this topic. However, different stakeholders have different decision making situations and objectives, as well as their technical knowledge vary widely. This paper deals with the question of how embodied impacts assessment can be integrated into the decision making of the main actors in order to improve sustainability in the construction industry. The focus is on the indicators "embodied energy" and "embodied greenhouse-gas emissions", and considering that they represent a part of Life Cycle Assessment (LCA), they can provide a first step into the subject of embodied impacts especially for those actors without extensive LCA experience. The analysis presented in the paper is partly built on the preliminary results of the ongoing project IEA Annex 57 "Evaluation of Embodied Energy & Carbon Dioxide Emissions for Building Construction" where the authors actively participate. More specifically, the paper discusses the most important questions and challenges in incorporating embodied energy and greenhouse-gas emissions considerations in decision making per selected actor group. A framework for the best possible use of existing information by these selected actor groups along the different stages of the building project is proposed to assist them in making informed decisions. Finally, the framework is organised in a matrix showing which decision making situations are typically related to each specific role of the selected actor groups, how these are influenced by this new requirement and what are the very specific data that can be fed into the different important decisions taken along the building project life cycle.

## Fate, Effects and Risk Assessment of Metals: Regulatory Perspective

436

### Assessing organism recovery after multiple pulse exposures to the trace metal magnesium, using *Hydra viridissima* (Green hydra)

A. Prouse, Ecotoxicology Research Group School of Applied Sciences; A.C. Hogan, NRA Environmental Consultants / Australian Government Department of the Environment; A.J. Harford, Dept. of the Environment / ERISS Environmental Research Institute of the Supervising Scientist Division; R.A. van Dam, ERISS / Australian Government Department of the Environment; D. Nugegoda, RMIT University / School of Applied Sciences  
Water quality guidelines for trace metals are usually based on results from organisms subject to continuous exposure to the metal. In mine releases however, aquatic organisms are often be subject to pulse exposure to metals. The time taken for organisms to recover from a pulsed toxicant exposure is an important consideration necessary when applying water quality guidelines (WQGs) to intermittent events in the environment. Organisms may appear to have recovered using standard toxicity testing methods but could carry residual toxicant or damage that may make them more sensitive to subsequent pulses. Such cumulative effects may render guidelines under-protective. The current study evaluated recovery of a sensitive freshwater cnidarian, *Hydra viridissima* following single, double and multiple pulse exposure to the trace element magnesium. *H. viridissima* were exposed to 4-h magnesium pulses of 790 and 1100 mg/L separated by 2, 10, 18, 24, 48 and 72-h recovery periods. Twenty four-hour pulses of 570, 910 and 940 mg/L were separated by 24, 48 and 168-h recovery periods. Apparent recovery after a single pulse of 4-h or 24-h was considered to have occurred once the population growth rate of the pulsed treatments returned to that of the controls. Double pulse toxicity tests were conducted using a second 4-h or 24-h Mg pulse to match the first pulse, with inter-pulse periods of 24, 72, 168 and 240 h. All treatments showed similar or reduced sensitivity to the second pulse when compared with sensitivity to the single pulse, indicating full recovery occurred prior to a second pulse-exposure. Five variations of equivalent time-weighted average concentrations were used to compare sensitivity of organisms to various pulse scenarios. The sensitivity of hydra to the multiple pulses was significantly lower than the time-weighted average continuous exposure response in three of the four scenarios tested, indicating that the hydra benefited from inter-pulse recovery periods. The results will be utilised with that of other species to inform the use of a site-specific, duration-based WQG for Mg and provides an example of the use of empirical data in the regulation of toxicant pulses in the environment.

437

### Setting Water Quality Objectives for the Rum Jungle Remediation Project

R. Smith, A. Markham, Hydrobiology Pty Ltd; T. Laurencont, Northern Territory Department of Mines and Energy  
In early 2013 the Northern Territory Government Department of Mines and Energy completed a study of the environmental values downstream of the former Rum Jungle Mine site. The purpose of the study was to describe the receiving environment in terms of its key ecological and geomorphological characteristics, identify environmental values of importance to the stakeholders, particularly traditional Aboriginal owners (traditional owners), and set appropriate water quality objectives for rehabilitation of the mine based on those environmental

values. The study was undertaken by a team of scientific experts with a range of relevant technical skills and a detailed knowledge of the area. The team undertook a careful review of historic data and scientific reports, conducted a field inspection and held consultation meetings with key stakeholders including traditional owner groups. From the information gained from this exercise, the relevant environmental values for each river reach from upstream of the mine area to the coast were identified, and draft water quality objectives developed from trigger values identified for each environmental value. Further stakeholder consultation resulted in the adoption of those water quality objectives for the remediation, pending further investigations to develop locally derived water quality objectives. This project will be described as an example of the application of the proposed water quality management framework that has been developed as part of the current revision of the ANZECC/ARMCANZ (2000) water quality guidelines.

438

### Metal bioavailability: Identifying regulatory monitoring priorities

D. Leverett, A. Peters, Wca Environment Ltd.; R. Clarke, Sepa  
The move towards setting Environmental Quality Standards for metals on the basis of "bioavailable metal" concentrations in Europe presents some challenges for regulators in assessing compliance against these standards. The change from standards which have typically been based on water hardness alone, or are not considered to be affected by water chemistry, means that the compliance situation for these metals may change. It cannot necessarily be assumed that areas where the potential risk due to metals has historically been perceived to be high will continue to be the greatest priority. An important problem which may environmental regulatory authorities throughout Europe are faced with is the lack of available monitoring data for the supporting parameters (principally pH, DOC, and calcium) which are required to perform metal bioavailability assessments. In order to maximise the number of locations for which metal bioavailability estimates could be made all of the available monitoring data obtained over a 20 year period was collated, and average values of the relevant parameters were calculated for each site for all of the data available over the entire period. Metal bioavailability was calculated for the average bioavailability conditions at sites with reported metal exposures using chronic biotic ligand models for copper, manganese, nickel and zinc. Compliance against standards for cadmium and lead were assessed against the standards set under the Water Framework Directive, as a function of hardness and DOC concentrations respectively. The sensitivity of the receiving environment depends upon the local water chemistry, and the effect of water chemistry can differ for the different metals due to their differing interactions with both the biota and the water chemistry conditions. Initial indications are that overall the risk posed by metals in Scottish freshwaters is low, although there are a number of isolated sites where metal exposures are of concern. Sites for which metal exposure information is available, but without sufficient water chemistry information to estimate metal bioavailability were not included in this assessment. The spatial distribution of the potential risks posed by each of the metals to the Scottish surface water environment will be presented, along with estimates of the cumulative risk posed by mixtures of metals in these situations.

439

### Water quality assessment: the use of biotic ligand model-based software applications to address the bioavailability of metals

H. Ruedel, Fraunhofer IME - Institute for Molecular Biology and Applied Ecology / Environmental Monitoring  
In this contribution the use of software applications based on biotic ligand models (BLM) for the evaluation of monitoring data of metals in the context of the European Water Framework Directive will be discussed. BLM-based applications have been developed to allow a user-friendly local evaluation of the bioavailability of metals. Therefore local quality standards (QS; protection goal: pelagic communities) are calculated as a function of water quality parameters. The original complex BLM developed primarily in the context of EU chemicals risk assessment require about 10 water quality parameters. In contrast, the available BLM-based software applications only need up to three parameters (water hardness, dissolved organic carbon concentration (DOC), pH) and the dissolved metal concentration (operationalized as concentration after 0.45 µm-membrane filtration). Two BLM-based software applications, Bio-met (www.bio-met.net) and PNEC.pro (www.pnec-pro.com) are available which allow both the evaluation for three metals (Cu, Ni and Zn). The dependencies of the calculated local QS on the parameters hardness, DOC concentration and pH are described and the results of the evaluation of representative scenarios for both applications compared. Based on the results of this study recommendations regarding the future use of BLM-based software applications for accounting the bioavailability of metals in the evaluation of water quality are derived.

### Fate of tin in aqueous media: implications for the validity of ecotoxicity testing

I.A. Wilson, A. Peters, Wca Environment Ltd.; G. Merrington, Environment Agency; J. Pearce, P. Cusack, K. Nimmo, J. Rickwood, ITRI  
Soluble tin [Sn] salts undergo rapid precipitation in aqueous media which can cause problems when performing ecotoxicity tests on these substances. There is a need to meet regulatory requirements on the environmental risk assessment of Sn and Sn compounds, in particular reliable effects data from standard ecotoxicity testing.

Ecotoxicity tests in which effects are caused by physical factors by precipitated solid particles should not be used for either classification or risk assessment. It is essential to avoid test conditions which could result in the precipitation of material during the test. Experiments were performed with tin (IV) chloride at a range of environmentally relevant concentrations in OECD T-D test media at nominal pH's of 6, 8 and 8.5. The results demonstrated that the time to equilibrium in all tested media was typically at least 14 days. The shortest equilibration times were observed at low spike concentrations and at high pH. The equilibrium concentration is controlled by the pH, the solubility of the possible precipitated solid phases, and the formation of negatively charged sites on the surface of the Sn precipitates may result in further binding of Sn cations. The data produced from the experiments was used to produce predictive Sn precipitation models which were used to predict the behaviour of Sn in old ecotoxicity tests. The majority of historic ecotoxicity tests failed the outline criteria due to the possibility that the test subjects were exposed to precipitating solutions during testing. For these historic tests it is not possible to establish the exposure concentration of tin to the aquatic organisms. How the results of any such testing might be used within a regulatory framework should be discussed with the relevant authorities prior to conducting any further tests.

#### 441

##### **Global assessment of manganese emissions from extraction and processing**

R. Marks, WCA Environment; A. Peters, Wca Environment Ltd.; D. McGough, A global environmental risk assessment has been conducted in order to assess the environmental risks due to manganese emissions from the manganese extraction and processing facilities around the world. Where possible, a quantitative risk assessment has been conducted to determine the potential environmental risk. For some sites the available data does not allow for a quantitative risk assessment, and for these sites a qualitative assessment has been carried out. This study provides a generic risk assessment of manganese production and use sites, in order to identify factors that affect risk to the environment. The principal sites producing or using manganese fall into three broad categories. These are mining sites, refining and smelting sites, and sites producing chemicals and pigments. There are two principal approaches towards waste disposal, these are the treatment of liquid wastes to separate solids for disposal off-site with a consented wastewater discharge, or disposal on-site through the use of evaporation or settlement ponds in order to maintain the waste materials in a suitable manner following site closure. Leaching of manganese due to water infiltration, or windblown dust, from tailings piles are considered to be the most likely routes of emission of manganese to the surrounding environment from manganese mining sites and other manganese processing sites which use similar emission control strategies to maintain waste materials on-site. On-site engineering is likely to be highly influential in the potential for losses of manganese to the surrounding environment from the sites. The principal source of emissions from refining sites and smelters with wastewater discharges is from the treatment of emissions to air. This is typically carried out using wet scrubber air filters to collect the particulate materials. The effluent from this process is typically then treated on-site, with solid waste removed off-site, prior to discharge. Sites of this type may also hold relatively large stockpiles of raw materials on-site, and the interaction of rainfall with these stockpiles may also potentially result in small environmental emissions of manganese. A generic risk assessment for direct emissions to surface waters has been conducted for several indicative tonnage bands. These emission calculations assume that wastewater discharges are treated on-site prior to release into surface water, where a limited degree of dilution may be available.

#### 442

##### **Long-term effects of inorganic and synthetic fungicides on leaf-associated microorganisms and leaf-shredding macroinvertebrates - an artificial stream study**

J.P. Zubrod, Institute for Environmental Sciences University of Koblenz-Landau / Institute for Environmental Sciences; J. Wolfram, University of Koblenz-Landau / Institute for Environmental Sciences; D. Englert, Institute for Environmental Sciences / Institute for Environmental Sciences; R. Bundschuh, Institute for Environmental Sciences University of Koblenz-Landau / Institute for Environmental Sciences; R.R. Rosenfeldt, University of Koblenz-Landau, Institute for Environmental Sciences / Institute for Environmental Sciences; F. Seitz, Inst. for Environmental Sciences / Institute for Environmental Sciences; R. Schulz, University of Koblenz-Landau / Institute for Environmental Sciences; M. Bundschuh, Department of Aquatic Sciences and Assessment Swedish University of Agricultural Sciences / Department of Aquatic Sciences and Assessment In the ecosystem process of leaf litter breakdown, microorganisms (especially fungi) are of fundamental importance as they govern the nutritious quality of leaves (i.e. conditioning) for leaf-shredding macroinvertebrates – the main drivers of leaf mass loss. Although fungicides affect both groups of organisms and are assumed to be continuously present in agricultural streams, their long-term effects in leaf-associated microbial communities as well as shredder populations have barely been studied. Therefore, we assessed structure and functioning of leaf-associated microbial communities and populations of the key shredder *Gammarus fossarum*

over eight weeks in artificial streams that were continuously fed with fungicide-spiked water using three treatments: a fungicide-free control and exposure to the inorganic fungicide copper (Cu, 25 µg/L) or a mixture of five synthetic fungicides (25 µg/L in total). In one stream per treatment leaf bags were deployed to follow the dynamics of microbial colonization and leaf mass loss. In the same streams, sets of leaves were conditioned for 12 days to provide gammarid populations ( $n=7$ ) with fresh food of relatively constant quality on a weekly basis. The amphipods were thus subjected to combined fungicide stress, i.e. fungicide-affected food and waterborne exposure. Both Cu and the mixture of synthetic fungicides did not alter microbial leaf mass loss but reduced leave-associated fungal biomass from day 28 onwards, indicating a reduced food-quality for shredders. Moreover, both fungicide treatments reduced leaf consumption, precopula pair formation and production of juveniles by *Gammarus* populations, while only Cu reduced feces production as well as the abundance of adult gammarids. Further analyses are underway to develop a mechanistic understanding of the observed effects. Nonetheless, our results clearly show that long-term continuous exposure towards environmentally relevant fungicide concentrations affects i) the structure of leaf-associated microbial communities and thus potentially food-quality for shredders as well as ii) structural and functional traits of the key shredder *Gammarus* on the population level, suggesting far-reaching consequences for detritus-based aquatic food webs.

#### 443

##### **Effects of fungicides on decomposer communities and leaf decomposition in streams**

D. Fernández, K. Voss, University Koblenz-Landau / Quantitative Landscape Ecology; J.P. Zubrod, Institute for Environmental Sciences University of Koblenz-Landau / Institute for Environmental Sciences; M. Bundschuh, Department of Aquatic Sciences and Assessment Swedish University of Agricultural Sciences / Department of Aquatic Sciences and Assessment; R.B. Schaefer, University Koblenz Landau / Institute for Environmental Sciences Large amounts of fungicides are applied globally and partly enter freshwater ecosystems. While effects of insecticides and herbicides on organic matter processing, which represents an important ecosystem process, have often been reported in the literature, only a few studies focused on the effects of fungicides. We present results from the first field study on the effects of fungicides on leaf litter decomposition and microbial and leaf-shredding macroinvertebrate communities. Moreover, compounds identified as ecotoxicologically relevant in the field were tested for effects in laboratory microcosms and in a stream mesocosm study, also considering potential interactions between nutrients and fungicides. The field study was conducted in 17 streams in a German vineyard area, where fungicides represent the dominant pest control agent. Fungicides were monitored during 4 rainfall events using passive samplers. Fungicide toxicity ranged from -4 to -2 log sum of toxic units. The structure of microbial and invertebrate communities changed along the gradient of fungicide toxicity. Changes in fungal community structure were also identified under laboratory conditions for fungicide mixtures from the field. Moreover, fungal biomass and richness decreased in the field in association with increasing toxicity. These changes might explain the reduction of the microbial OMD rate of up to 40% in polluted streams. By contrast, neither the invertebrate OMD rate nor the gammarid feeding rate correlated with fungicide toxicity. Our results suggest that fungicide exposure in the field can affect microbial communities and may reduce microbial OMD. However, further studies should test for causality of the observed associations and scrutinise effect mechanisms of fungicides on OMD.

#### 444

##### **Ecological risk assessment based on an ecosystem services approach for pesticides in tropical regions**

A.L. Sanchez, USP / São Carlos Engineering School; L. Mendes, University of São Paulo; E.G. Espindola, University / Hydraulics and Sanitation Ecological risk assessment studies are important to assess environmental changes that have been caused by various anthropogenic activities, such as leaching of contaminated areas, input of domestic and industrial sewage, runoff of agricultural areas and other impacts, which are responsible for physical, chemical and biological alterations. The latest biodiversity conservation studies have shown an interest in the other side of conservation: the goods and services that ecological systems can provide to human societies. These ecosystem services are the result of complex interactions between abiotic and biotic components and the evaluation structures are intended to include the role of human beings in these interactions. In this context, the focus of this research was evaluated the ecological risk assessment for pesticides and incorporating ecosystem services concepts for tropical regions. To attempt it, the risk scenario was architected based on recommended doses of the fungicide Pyrimethanil for agriculture cultures. For this simulation were used a gradients of concentrations, demonstrating multiple applications on crop situations through seed germination tests, elutriated tests coming from the plant tests with aquatic organisms and avoidance tests with soil organisms. The results obtained suggest that the triad analysis (based on chemical, ecotoxicological and ecological measures), indicated that risks were higher in increasing the recommended dose. The ecotoxicological risks showed a toxicity trend with increasing the recommended dose for the different tests and tested organisms and for ecological parameters of the environmental risk analysis were used the changes and loss of the

ecosystem services concepts which are potentially affected by the fungicide. In addition were categorized the ecosystem services as provisioning for germination tests, regulating for elutriated tests and supporting for avoidance tests. This measurement showed more accuracy in the environmental impacts on the structure and functioning of natural ecosystems making it an important tool for risk management programs for the pesticides in the tropical regions. We concluded that the original ecological risk trends and potential projections of the studies for use in diagnostic of environmental impacts were more relevant when included new analyzes factors such as the measurement of the effects of contaminants on the functions and ecosystem services in disturbances areas.

445

#### **How effective are risk mitigation measures to protect surface water? A modelling approach**

L. de Baan, O. Daniel, Agroscope / Institute for Plant Production Sciences IPS  
To reduce unwanted side effects of pesticide use on surface water organisms, different mitigation measures exist. In Switzerland, a set of risk mitigation measures are in place. The aim of the present study was to evaluate the effect of different risk mitigation measures on the acute risk to aquatic organisms. We modelled how different pesticide usage scenarios in wheat affect the potential risk to a set of aquatic organisms. Five scenarios were evaluated: (1) no minimum distance to surface water, (2) minimum distance of 3 meters to surface water, (3) minimum distance of 6 meters to surface waters, (4) Product-specific buffer zones enacted in Switzerland by the end of 2013, (5) "Extenso" label production: only applying herbicides and adhering to a minimum distance of 6 meters. SYNOPSIS was used to model the risk of a set of pesticide usage scenarios in wheat production in Switzerland, using pesticide survey data of totally 420 wheat fields from the Swiss agro-environmental monitoring program. Mandatory minimum distances of spray applications to surface water can largely contribute to minimize the risks of pesticide spray drift for aquatic environments, reducing the risk to about 1% (3m) and 0.5% (6m) respectively. The compliance with such measures is relatively easy to control compared to the compliance with product-specific buffer zones. For products where side-effects on water organisms are expected to be large, an additional, product-specific buffer zone to surface water bodies can reduce concentrations of these problematic products and the related ecotoxic effects by up to 100%. Label wheat production also significantly contributed to reduce risks and avoiding the usage of insecticides and fungicides could nearly bring the modelled risk to zero for water fleas, fish and midges. In summary, all risk mitigation measures showed positive effects and the combination of measures, e.g. scenarios 3 and 4 or scenario 5, is expected to be most effective to mitigate risks to acceptable levels. In this study, we modelled effects of risk mitigation measures for the exemplary case of wheat production. If the results from wheat can be transferred to other cultures, especially to cultures with higher expected risk from spray drift such as orchards or vineyards, needs to be further evaluated.

446

#### **The combined effect of diffuse pollution from agriculture and climate change on aquatic biota.**

V. Silva, Universidade de Aveiro / Department of Environment and Planning and the Centre for Environmental and Marine Studies CESAM; C. Marques, University of Aveiro / Department of Biology; J. Keizer, Department of Environment Centre for Environmental and Marine Studies CESAM University of Aveiro Aveiro Portugal; F. Goncalves, University of Aveiro CESAM / Department of Biology; N. Abrantes, University of Aveiro / CESAMDAO

Agriculture is already recognized as an important source of contaminants to the adjacent freshwater systems, compromising water quality and causing toxicity in aquatic organisms. Climate change poses an additional threat to these ecosystems, namely by increasing the water temperature and the concentration of contaminants, but the combined effects of stressors - diffuse pollution from agriculture and climate change - remains poorly understudied. Therefore, through an experiment in microcosms (a more realistic scenario exposure), it was evaluated the combined effect of chemical contamination of water by copper sulfate, a fungicide commonly detected in water bodies adjacent to vineyard areas, in conjunction with a range of increases in water temperature on the response of freshwater species from different functional groups. Thus, the adverse effects on the growth of primary producers (algae *Raphidocelis subcapitata* and macrophyte *Lemna minor*) and on the survival and feeding behavior of a shredder/decomposer species (*Trichoptera Schizopelex* sp.) were evaluated. The results showed that (i) copper-based fungicides, highly applied to control vine diseases such as downy or powdery mildew, can exert adverse effects on survival, growth and activity of aquatic organisms, reinforcing the problem of toxic effects of pesticides on non-target organisms and the need of more effective environmental management strategies. Furthermore, the results showed that (ii) the expected increases in water temperature by climate change will accelerate the metabolism of organisms at the same time that increases exposure and toxicity of contaminants. Provided the significant ecological roles of tested organisms (namely on the energy and nutrients flows), such results raise serious concerns about the additional impacts/vulnerabilities caused by climate change on water resources already impacted by diffuse pollution from agricultural sources.

**Key-words:** Experience in microcosm, diffuse pollution from agricultural sources, climate change, aquatic biota.

447

#### **Developing ecological scenarios for the prospective risk assessment of pesticides**

A. Rico, Wageningen University / Environmental Risk Assessment; T.C. Brock, Alterra / Environmental Risk Assessment; A. Focks, Alterra Wageningen University and Research Centre / Ecotoxicology Environmental Risk Assessment Team; P.J. van den Brink, Alterra and Wageningen University  
Most specific protection goals that underlie Ecological Risk Assessment (ERA) schemes for pesticides focus on the protection of populations of non-target organisms. Particularly in the case of terrestrial and aquatic non-target invertebrates and plants some pesticide effects may be allowed if population recovery is achieved within a given spatio-temporal frame. An important question for ecotoxicologists and risk evaluators is whether the (combination of) species and spatio-temporal frames currently used in ERA provide a realistic and conservative protection level for the exposed populations and communities under field conditions. We propose to approach this issue by systematically defining ecological scenarios that represent the impacted ecosystems and that can be linked to the already existing exposure scenarios to perform higher-tier evaluations e.g. using ecological models. In this study, we present and discuss a methodological approach for the formulation and implementation of ecological scenarios in the prospective risk assessment of pesticides, that can also be extrapolated to other chemicals. The proposed approach combines (bio)monitoring data, available toxicity data and relevant biological trait information to identify potentially vulnerable taxa. Following this approach, ecological scenarios will include: (1) a series of abiotic parameters (e.g. physico-chemical characteristics, descriptors of (agro)ecosystem management and landscape configuration), (2) a selection of vulnerable populations and their ecological interactions, (3) and a spatio-temporal frame that is relevant for the selected vulnerable populations. We propose the development of generic ecological scenarios for different landscape units (e.g. ponds, streams, ditches) in EU, and envisage three main areas in which ecological scenarios can be effectively used to support and improve ERA: (1) the identification of conflicts of interest between different protection goals, (2) the evaluation and design of laboratory and semi-field toxicity studies, and (3) the evaluation and motivation of the biotic and abiotic components included in eco(toxicological) modelling. In this presentation, we will provide practical examples on how ecological scenarios can aid to these three tasks by describing a case-study for Dutch agricultural ditches.

#### **Reduction strategies of micropollutants from large and small-scale sewage water facilities (I)**

#### **Decision support for stakeholders in a river catchment; how to act on emerging contaminants**

A. Fischer, Faculty of Civil Engineering and Geosciences; A. van Wezel, KWR Watercycle Research Institute / Chemical Water Quality and Health; J. van der Hoek, Water Management  
Emerging substances (ES) in surface water increasingly give concern to the public, regulators and users of this water. Water authorities and utilities struggle to define where and how to combat these substances in the water cycle. Different strategies are available; from preventing the compounds entering the water cycle to end-of-pipe solutions such as removal of the substances at drinking water treatment plants. In case of treatment, several technologies are available, which further complicates the selection of the most effective strategy. The EU Interreg project TAPES (Transnational Action Programme on Emerging Substances) aims to address this issue. Part of the project is to develop a decision support system (DSS) to facilitate local stakeholders with their task to decide on the most effective strategies to control ES within their segment of the water cycle. By interviews with various stakeholders, their main issues were identified: *no overview of ES in water (sources, measures, treatment technology and location of measures)* how to locally define if a water body has problems with ES; what are the effects on human health and the ecosystem With these issues identified, a practical DSS framework has been outlined. A prototype is built based on this framework and will be shown. The final DSS, clustering existing knowledge, is giving the user information on the source, pathway, chemical characteristics and toxicity of individual emerging substances. Next, it provides information on the efficiency of various water treatment technologies in removing the specific substance. Finally, the DSS gives suggestions how to deal with relevant ES with regards to mitigation methods within the categories technical-, managerial- and social solutions The DSS prototype is used in two test cases. The first being a Belgian drinking water company that aims to expand their drinking water treatment with an extra step of advanced drinking water treatment. The second case is a Swiss wastewater treatment plant where the DSS will be used to define what treatment steps are of interest to step specifically remove ES from wastewater effluent. The DSS will help actors in the water cycle for a better informed decision-making, and a more effective and uniform way of managing emerging substances.

449

#### **Screening of micropollutants in wastewaters from on-site sewage treatment facilities and evaluation of current treatment techniques**

In Sweden, approximately 700 000 private households are not connected to public sewage treatment plants (STPs). Conventional centralised STPs are not economically feasible for sanitation of these sparsely populated areas, and therefore more cost-effective on-site sewage treatment facilities (OSSFs) are used. Most of these consist of a sludge separation with subsequent treatment with soil or infiltration beds, while a small percentage of on-site sewage treatment facilities (~2%) are based on small wastewater treatment facilities. The treated wastewater is thereafter drained to surface water or groundwater. In this study, we developed an analytical strategy to identify and prioritize ecological relevant micropollutants in wastewaters from OSSFs. For chemical characterization, both target analysis, using LC-MS/MS, and suspect screening, using an Orbitrap Velos<sup>TM</sup> High Resolution Mass Spectrometer (HRMS) followed by exact mass compound databases, were used. The occurrence of candidate substances identified by the suspect screening approach was later confirmed by analytical standards. With this analytical strategy, approximately 80 micropollutants, belonging to different chemical classes, were successfully identified, such as per- and polyfluoroalkyl substances (PFASs), pesticides, endocrine disrupting chemicals (EDCs), organophosphate flame retardants (OFRs), pharmaceuticals (PhACs) and personal care products (PCPs). Furthermore, the removal of identified micropollutants under small waste water treatment plants and soil bed treatments was assessed and compared to the removal efficiencies observed in large scale STPs. Finally, a prioritization strategy based on removal efficiencies in OSSFs facilities, concentration levels, frequency of detection and toxicity, persistency and bioaccumulation data, which were obtained from *in silico* tools, was applied to identify the most ecologically relevant micropollutants emitted from OSSFs.

##### **Assessment of five different full-scale small wastewater treatment technologies for removing emerging contaminants**

V. Matamoros, Y. Rodríguez, IDAEA CSIC

Nowadays, there is a large part of the population that live in small communities (*Daphnia magna*). The concentration of ECs in the wastewater influents was higher than 10 µg/L for caffeine, paracetamol, methyl dihydrojasmonate and ibuprofen, whereas most of the other compounds were found at concentrations below 1 µg/L. The removal efficiency ranged from negligible removal to more than 90% depending on the compound. The WSP manifested the highest overall average removal efficiency for ECs (86%, on average), followed by the AS (74%), the RBC (68%), the TF (64%) and finally the CW (48%). A principal component analysis showed that the treatment technologies with predominantly aerobic conditions (WSP, AS and RBC) exhibited the highest removal efficiencies. The ecotoxicological risk assessment study revealed that wastewater influents possessed hazard quotients (HQs) of higher than 1, whereas the wastewater effluents had HQs < 1. Hence, it can be said that all evaluated treatment technologies are capable of decreasing toxicity risk (*Daphnia magna*) associated with the studied ECs.

#### 451

##### **Removal of emerging micropollutants from wastewater discharges by powdered and micro-grain activated carbons - Case study of the CarboPlus® process**

R. Mailler, J. Gasperi, LEESU / Leesu; Y. Coquet, SAUR; S. Deshayes, Paris-Est University / Leesu; S. Zedek, LEESU laboratoire eaux environnement et systèmes urbains; A. Bulete, Institut des Sciences Analytiques UMR TRACES Team / Service Central d'Analyse; E. Vulliet, CNRS; V. Eudes, Laboratoire Central de la Préfecture de Police; A. Bressy, Paris-Est University / Leesu; E. Caupos, Université ParisEst LEESU UMRMA UPEC ENPC AgroParisTech UPEMLV / Leesu; R. Moilleron, G. Chebbo, Paris-Est University / Leesu; V. Rocher, SIAAP

The implementation of a tertiary treatment in conventional wastewater treatment plants is more and more considered by managers to reduce the emerging contaminant discharges into the aquatic environment. In this context, a collaboration between the public sanitation service of Paris conurbation (SIAAP) and the Water Environment and Urban Systems laboratory (LEESU) has been initiated to study at large scale a pilot (CarboPlus® - SAUR/STEREAU) based on a high concentration fluidized bed of activated carbon (>100 kg/m<sup>3</sup>) with continuous fresh activated carbon injection. The objectives of this project are to i) characterize the efficiency of the process for emerging pollutants and conventional wastewater quality parameters for powdered (PAC) and micro-grain (µGAC) activated carbons, and ii) characterize the parameters influencing the sorption mechanism (organic matter, operating parameters, activated carbon structure and properties, etc.). In addition to the 14 campaigns already performed in 2013 in PAC configuration, 14 campaigns have been planned in 2014 (8 already performed) to

study the fate of 131 micropollutants, including 61 pharmaceuticals and hormones and 70 other emerging pollutants, in addition to conventional wastewater parameters. This presentation aims at displaying the pilot efficiency in µGAC configuration and comparing it to the PAC configuration. The use of µGAC instead of PAC has several operational and economical advantages, but this new type of carbon was never tested with wastewater. Based on the first 8 campaigns, the results tend to indicate that the pilot is as efficient with µGAC than with PAC. In particular, ketoprofen, paracetamol, ibuprofen, ofloxacin, ciprofloxacin, trimethoprim, roxithromycin, atenolol, propranolol, carbamazepine, oxazepam, lorazepam and estrone have removals higher than 80% in average. In addition, first results on the other emerging micropollutants show high or very high removals for pesticides (60-95%), bisphenol A (60-90%), alkylphenols (60-95%), PFOS (75-95%) and X-ray contrast agents (50-70%). Moreover, the high solid retention time (60-90 days) of the µGAC leads to a biological activity within the reactor, as displayed by NO<sub>2</sub><sup>-</sup> (65-99%) and NH<sub>4</sub><sup>+</sup> (20-70%) removals. However, the results are still partial at this stage of the project, another µGAC dose is currently tested on the pilot and complementary lab-scale tests are still performed to better understand the sorption mechanism.

#### 452

##### **Evaluating advanced biological wastewater treatment in a bioassay-based approach**

J. Völker, Aquatic Ecotoxicology; S. Castronovo, A. Wick, Federal Institute of Hydrology; T. Ternes, Bundesanstalt für Gewässerkunde; A. Joss, Process Engineering Swiss Federal Institute of Aquatic Science and Technology EAWAG; J. Oehlmann, Johann Wolfgang Goethe-Universität Frankfurt / Aquatic Ecotoxicology; M. Wagner, Goethe University Frankfurt / Aquatic Ecotoxicology

During conventional activated sludge treatment of wastewater, micropollutants such as pharmaceuticals and biocides are often not completely removed. This leads to a continuous discharge of a broad spectrum of emerging pollutants in the receiving rivers and results in potentially adverse impacts on aquatic ecosystems. One of the aims of the ERC project *Athene* is to explore the potentials and limits of various biological wastewater treatment processes for the removal of organic micropollutants and detoxification. Therefore, long-term experiments at pilot scale with 15 different set-ups were conducted directly at two medium-sized wastewater treatment plants (WWTP Koblenz, Germany and WWTP Dübendorf, Switzerland). The aim of the present study was to investigate the removal of toxicity by these processes using a broad battery of *in vitro* bioassays. The pilot plant located at the WWTP Koblenz consisted of six 12 L sequence batch reactors fed with effluent of the primary clarifier. Based on previous results from micropollutant analysis, two promising treatments were selected for toxicity testing (anaerobic pre- and post-treatment combined with conventional activated sludge treatment). For the *in vitro* analyses, we conducted four sampling campaigns in summer 2014. To investigate the removal of toxicity, SPE extracts were analysed in *in vitro* bioassays covering a broad range of modes of actions, including endocrine and dioxin-like activity, cytotoxicity and genotoxicity. So far, the results indicated that the implementation of an anaerobic pre-treatment in addition to conventional biological treatment is a promising approach for a significant decrease of wastewater-borne toxicity. For example, an additional removal of estrogenic activity (Yeast Estrogen Screen) and bacterial cytotoxicity (Microtox) was observed. The pending results of further experiments will show whether this results can be confirmed. Sampling strategy, suitability of different *in vitro* endpoints and the results of an ongoing screening campaign will be presented and discussed. Financial support from the European Research Council (ERC) through the EU-project *Athene* is gratefully acknowledged.

##### **Biodegradation kinetics and fate of Benzotriazoles and Hydroxy-benzothiazole in activated sludge and suspended biofilm systems**

A.A. Mazioti, Aegean University / Environment; A.S. Stasinakis, University of the Aegean / Department of Environment; H. Andersen, DTU Technical University of Denmark / Department of Environmental Engineering; Y. Pantazi, University of the Aegean / Department of Environment

Benzotriazoles and benzothiazoles are two groups of compounds used in industries, part of the large family of emerging pollutants. They are found in wastewater at concentrations of some ng L<sup>-1</sup> to some µg L<sup>-1</sup>. They may cause serious damage to aquatic environment and organisms as well as creating problems in water reuse, when not eliminated efficiently. In order to examine and specify the elimination of 1H-benzotriazole (BTR), 5-Chloro-benzotriazole (CBTR), 5,6-dimethyl-1H-benzotriazole (XTR) and 2-hydroxy-benzothiazole (2OHBTH) during biological treatment, various laboratory experiments were conducted under batch and continuous-flow conditions. Batch experiments were conducted in the presence and absence of easily degradable organic substances and biodegradation as well as sorption kinetics were calculated. Continuous flow experiments were conducted under different operational parameters to determine removal rates of target compounds. For this reason, two continuous-flow, lab-scale systems were set in the laboratory; an activated sludge unit consisted of aerobic reactor and settling tank and a Moving Bed Biofilm Reactor (MBBR) system consisted of two reactors in series filled with biocarriers. According to batch experiments, their sorption constants varied from 87 to 220 L Kg<sup>-1</sup>, proving the general hypothesis that the compounds have a weak tendency to sorb onto organic matter. Biodegradation half

lives of target compounds varied from some hours to one or two days. The presence of easily degradable compounds seems to favor biodegradation of micropollutants, increasing their biodegradation constants. Removal rates in continuous flow experiments varied from lower than 50% (CBTR, XTR) to higher than 80% for 2OHBT. To the best of our knowledge, this is the first study comparing the biodegradation ability of activated sludge and biomass attached to biocarriers.

## Alternative approaches for ecotoxicity assessments (II)

### RTgill-W1 cell line assay for predicting fish acute toxicity: evaluation of a round-robin test

K. Schirmer, Eawag / Environmental Toxicology; M. Knöbel, Eawag, Swiss Federal Institute of Aquatic Science and Technology / Environmental Toxicology  
We aim to establish alternatives to toxicity tests with fish for chemical risk assessment and product development. One recent development has been the rainbow trout (*Oncorhynchus mykiss*) gill cell line, RTgill-W1, assay to predict fish acute toxicity. Based on pre-defined selection criteria, 34 organic industrial chemicals were tested and compared to the acute toxicity reported for these same chemicals in the US EPA fathead minnow data base. The toxicity of the majority of test chemicals was within a 10-fold range from the line of unity of the cell line versus the acute fish lethality if true exposure concentrations were taken into account. Moreover, the outcome of the cell line assay compared very well to results obtained in the zebrafish embryo toxicity test, which has meanwhile been accepted as the OECD test guideline 236. These findings provided the impetus to start bringing the RTgill-W1 cell line assay as a potential animal replacement method to the same level of international acceptance. Thus, with the support of CEFIC-LRI and UK NC3Rs, we initiated an international round-robin test to evaluate the transferability of the assay and intra- and inter-laboratory reproducibility. Seven laboratories provided data for this round-robin test either for testing chemicals in the cell line assay and/or confirmation of chemical concentrations in the testing plates at the start and end of the exposure period. These laboratories were, besides Eawag: Givaudan Schweiz AG (Switzerland); IRAS-Utrecht University (The Netherlands); The Procter & Gamble Company (USA); NIVA (Norway); RECETOX (Czech Republic); Vito-ABS team (Belgium). Chemical selection and quantitative analysis as well as the cell line assay followed previously described criteria and protocols. The RTgill-W1 cell line assay procedure was transferred in a straight-forward manner to the participating laboratories. Further improvements to the original SOP were implemented based on the suggestions provided by the participants and, in fact, led to further simplification. Completion of data from this round-robin will provide a solid base to quantify the intra- and inter-laboratory variability and help to further establish this assay as an animal-free alternative to the fish acute toxicity test.

### Effects of plastic and serum protein binding on cytotoxicity of cationic surfactants in vitro

N. Timmer, Utrecht University / Institute for Risk Assessment Sciences; F.A. Groothuis, Institute for Risk Assessment Sciences; E. Opsahl, Utrecht University / Institute for Risk Assessment Sciences; B. Nicol, Unilever RD Colworth / Safety and Environmental Assurance Centre SEAC; N.I. Kramer, Utrecht University / Institute for Risk Assessment Sciences; S.T. droge, Utrecht University / IRAS  
In vitro toxicity assays are envisaged to play a fundamental role in the risk assessment of industrial chemicals. Unfortunately, binding of chemicals to well plate plastic and serum constituents like bovine serum albumin (BSA) may lead to an underestimation of the toxicity. Binding affinities of cationic surfactants to such matrices is poorly understood. Therefore, this study assessed the cytotoxicity of twelve cationic surfactants, varying in carbon chain length (6-18 carbons) and ionic head group, in a basal cytotoxicity assay with the RTgill-W1 cell line. Cells in 48 and 96 well microtitre plates were exposed for 24-48 hours in serum-free exposure medium or medium containing either BSA (4 g/L) or 10% fetal bovine serum (FBS). After exposure, chemical concentrations in exposure medium and cells were measured using LC-MS/MS. Based on the nominal concentration of chemical in BSA/FBS free exposure medium, the cytotoxicity of benzalkonium chlorides increased almost 1000 fold with increasing chain length (and thus with hydrophobicity), but not after the alkyl chain contained more than 10 carbon atoms. Based on measured concentrations in BSA/FBS free exposure medium, however, the longer chained benzalkonium chlorides were significantly more toxic. Effect concentrations measured in BSA/FBS containing medium were up to a 60 fold higher. The findings indicate that the greater the chain length, the stronger the chemical binds to plastic and serum constituents, the lower the available fraction of the chemical is for causing cytotoxicity in cells. Based on cell-associated concentrations, there was little difference in the cytotoxic potency of the test chemicals because it is independent of assay setup. Such dose is more directly related to the chemicals modes of action (narcosis). Thus, using free and cell-associated concentrations allows for a more robust comparison of intrinsic cytotoxic potencies of surfactants in vitro.

### Primary gill cell culture representing organ functionality: Uptake, efflux and

### the first evidence of xenobiotic metabolism

L.C. Stott, Kings College, London / Division of Diabetes and Nutritional Sciences; S. Schnell, Division of Diabetes and Nutritional Sciences; C. Hogstrand, Kings College London / Division of Diabetes and Nutritional Sciences; S.F. Owen, AstraZeneca / Safety Health Environment; N.R. Bury, Kings College London / Division of Diabetes and Nutritional Sciences  
Worldwide, large numbers of fish are used in toxicology testing to determine the environmental effects of compounds that may be released into the aquatic ecosystem. In the UK last year, this number exceeded 42,000 fish. To find alternatives to such tests in line with the replacement, reduction and refinement (3Rs) of animals used in scientific research, surrogate *in vitro* cell models must be validated. As well as serving respiratory and excretory function, the fish gill is also the primary site of xenobiotic transport to and from the water. This study utilised an *in vitro* primary rainbow trout gill cell model, grown on permeable membrane inserts in a two-compartment model, which mimics the intact organ and can withstand apical freshwater application. Thus, environmentally relevant types and concentrations of pharmaceuticals can be added to the apical surface of the gill in the freshwater, like the *in vivo* scenario. This study aimed to describe the transport routes of pharmaceuticals across the *in vitro* gill and furthermore, aimed to show that the gill is metabolically active through cytochrome P450 (CYP P450) activity and is a 'first-pass' organ of waterborne xenobiotic metabolism in fish. Using radiolabeled compounds, the transport assays of 7 pharmaceuticals revealed that propranolol, metoprolol, ranitidine, terbutaline, formoterol and imipramine were transcellularly transported across the gill epithelium, whilst atenolol was not. Furthermore, the transport of propranolol was pH and concentration dependent and could be inhibited with the application of the inhibitors cimetidine, cyclosporine A, MK571 and quinidine, indicating it may also be transported via a carrier-mediated route. Cytochrome P450 assays indicated the presence of CYP1A, which may play a role in the metabolism of xenobiotics at the gill organ level. An appropriate solid phase extraction (SPE) method was optimised to analyse freshwater (the apical compartment) and cell culture medium samples (the basolateral compartment) after xenobiotic exposure at a range of concentrations over 24 hours. High-performance liquid chromatography (HPLC) analysis using a validated method confirmed the xenobiotic metabolic capacity of this primary gill cell culture, as the metabolite of propranolol, 4-hydroxypropranolol, was confirmed in both basal cell medium and apical water samples, indicating presence of metabolite uptake and efflux, respectively.

### Establishment of the first humpback whale cell lines and their application in chemical risk assessment

M. Burkard, Griffith University / Southern Ocean Persistent Organic Pollution Program; D. Whitworth, The University of Queensland / School of Veterinary Science; K. Schirmer, Eawag / Environmental Toxicology; S.M. Bengtson Nash, Griffith University / Southern Ocean Persistent Organic Pollutants Program SOPOP

Humpback whales have a high propensity for the accumulation of persistent organic pollutants (POPs) and therefore exposure to the health risks they pose. Few efforts have focused on the toxicological sensitivity of humpback whales due to the challenges associated with working on wild populations of large whales. Practical tools for deriving species-specific data has been identified as a pressing research need. This paper reports the first successful derivation and characterization of humpback whale cell lines. Primary cells were isolated from the dermal connective tissue of skin biopsies, cultured at 37°C and 5% CO<sub>2</sub> in the standard mammalian medium DMEM/F12 supplemented with 10% fetal bovine serum (FBS). Of nine initial biopsies, two cell lines were established from two different animals and designated HuWa1 and HuWa2. The cells have a stable karyotype with 2n = 44, which is identical to other baleen species. Cells were verified as being fibroblasts based on their spindle-shaped morphology and positive immunoreaction to vimentin. Population doubling time was determined to be ~41 h and cells were successfully cryopreserved and thawed. To date, HuWa1 cells have been propagated 20 times. Cells proliferate at the tested temperatures, 30, 33.5 and 37°C, but show highest rate of proliferation at 37°C. Short-term exposure to para,para'-dichlorodiphenyldichloroethylene (p,p'-DDE), a priority compound accumulating in humpback whales, resulted in a concentration-dependent loss of cell viability. The effective concentration which caused a 50% reduction in HuWa1 cell viability (EC<sub>50</sub> value) was approximately six times greater than the EC<sub>50</sub> value for the same chemical measured with human dermal fibroblasts. HuWa1 exposed to a natural p,p'-DDE-containing chemical mixture extracted from whale blubber showed distinctively higher sensitivity than to p,p'-DDE alone. Thus, we provide the first cytotoxicological data for humpback whales and with establishment of the HuWa cell lines, a novel *in vitro* model for the study of the whales' sensitivity and cellular response to chemicals and other environmental stressors.

### The fish embryo toxicity test as an alternative to the larval growth and survival test: Test sensitivity and alternative endpoints in zebrafish and fathead minnows

M.K. Sellin Jeffries, Texas Christian University / Department of Biology; A. Stultz, Miami University / Department of Zoology; A. Smith, Miami University; D.A. Stephens, K.S. Roush, Texas Christian University / Department of Biology; J.M.

Rawlings, The Procter & Gamble Company / Environmental Stewardship and Sustainability; S.E. Belanger, The Procter & Gamble Company / Central Product Safety Dept; J. Oris, Miami University / Department of Biology

The fish embryo toxicity (FET) test has been proposed as an alternative to the larval growth and survival (LGS) test. The objectives of this study were to evaluate the sensitivity of the FET and LGS test in fathead minnows (*Pimephales promelas*) and zebrafish (*Danio rerio*), and to determine if the inclusion of sublethal metrics as test endpoints could enhance test utility. In both species, LGS and FET tests were conducted using four reference toxicants and two mock effluents. A comparison of median lethal concentrations (LC50) determined via each test revealed significant differences between test types. However, no single test type emerged as the most or least sensitive for all of the chemicals and effluents tested suggesting that no single test type is universally the most or least sensitive. At the conclusion of the tests using mock effluents, developmental abnormalities and the expression of genes related to growth and toxicity were evaluated. Fathead minnows and zebrafish exposed to mock municipal wastewater treatment plant effluent in a FET test experienced an increased incidence of pericardial edema with increasing effluent dose and the median effective concentrations (EC50s) for such edema were less than the LC50 values suggesting that the inclusion of pericardial edema as a FET test endpoint could enhance test sensitivity. Significant alterations in the expression of genes including heat shock protein 70 (*hsp70*) and insulin-like growth factor (*igf*), were also noted. Specifically, fathead minnow and zebrafish exposed to mock effluents in the FET tests experienced significant increases in *hsp70* suggesting that stress-related biomarkers could be useful as an additional FET test endpoint. Exposures to mock effluents reduced the expression of *igf* among fathead minnows in the FET and LGS tests and zebrafish in the FET tests. Given the role of *igf* in development and growth, the observed decreases in its expression may be an indication of abnormal development or hindered growth. Data from the LGS tests supports this contention, as larvae with decreased *igf* expression weighed significantly less than larvae with control levels of *igf*. The results presented here not only show the utility of the fathead minnow FET test as a replacement for the LGS test, but provide evidence that inclusion of additional endpoints could improve the predictive power of the FET test.

## Invertebrate models in environmental toxicology (II)

### 459

#### Effects of heavy metals on the fatty acid profile of *Gibbula umbilicalis*

C. Silva, ESTM GIRM; T.F. Simoes, I. Pimparel, Polytechnic Institute of Leiria / ESTM GIRM; L. Granada, Escola Superior de Turismo e Tecnologia do Mar - Instituto Politécnico de Leiria; S.C. Novais, Polytechnic Institute of Leiria / ESTM and GIRM; M.F. Lemos, Instituto Politécnico de Leiria / Dept Biology

Fatty acids are carbon-rich compounds that are ubiquitous for all organisms and relatively easy to metabolize. Once incorporated in the organism, their biological specificity and the fact that they are transferred from primary producers to higher trophic levels without changing in characteristics, make fatty acids suitable for use as biomarkers. Different fatty acids have been found in mollusk species, and their relative proportion may be influenced by environmental conditions, nutrient habits, food availability and also physiological conditions. Heavy metals are among the most common environmental pollutants with natural or anthropogenic presence that can be easily biomagnified through the food chain. Marine gastropods are known to accumulate high metal concentrations in their tissues. Several characteristics of *Gibbula umbilicalis* make this sea snail a potential suitable species to be used in environmental risk assessment (ERA) studies. This work aimed to assess fatty acid profile changes in the gastropod *G. umbilicalis* exposed to metal contaminants. For that, the organisms were exposed for 168 hours to three different metals: Nickel (Ni), Cadmium (Cd) and Mercury (Hg). The 168h LC<sub>50</sub>s were 4,27 mg of Ni/L, 2,67 mg of Cd/L and 0,41 mg of Hg/L. After the lethality test, a sublethal 168h exposure was performed and the following lipid related endpoints were measured: 1) total lipid content; 2) lipid peroxidation (LPO); 3) fatty acid profile (FAP). No statistical significant differences were found in the total lipid content of any of the metal treatments tested and no increases in the LPO levels were seen, suggesting no oxidative damage on the membrane lipids. Results of the FAP showed that after the different metal exposures there were significant increases in the content of mainly polyunsaturated fatty acids implicit in immune and inflammatory responses and related with higher membrane fluidity. While commonly used lipid related endpoints did not show clear responses to the tested metals, FAP showed indication of membrane disorganization and anti-inflammatory responses by the increase of target polyunsaturated FAs. Therefore, FAP revealed to be a sensitive and more informative parameter and thus constitutes a promising tool to understand mechanisms of toxic action in *Gibbula umbilicalis*.

### 460

#### Freshwater planarians in ecotoxicology. A case study evaluating sub-lethal effects of TBT on *Schmidtea mediterranea*

P.U. Ofoegbu, Biology; C. Gravato, University of Porto / Laboratory of Ecotoxicology; A.S. Cruz, CESAM & University of Aveiro / Biology; S. Mendo, University of Aveiro / Department of Biology CESAM; A.M. Soares, Universidade de Aveiro / Department of Biology and CESAM; J.L. Pestana, CESAM & University of Aveiro / Department of Biology and CESAM

Planarians share with more complex organisms many neurotransmitters as well as their receptors, and show an incredible capacity for tissue regeneration. The freshwater planarian *Schmidtea mediterranea*, one of the best characterized animal models for regeneration studies and developmental biology, is easily kept in the laboratory and it is recognised as a potential useful species for ecotoxicological assays. Moreover, sensitive endpoints associated with behaviour and regeneration can be easily evaluated after exposing planarians to environmental contaminants. In this study we assessed the sensitivity of *S. mediterranea* to a gradient of environmentally relevant concentrations of TBT, after 48 hours of exposure, using a range of endpoints, commonly used in planarians, such as locomotor velocity, head regeneration and DNA damage. Moreover a new feeding assay based on the planarian predatory behaviour was developed. Results show that TBT exposure significantly reduced locomotion and feeding in planarians. In addition, TBT also significantly delayed head regeneration and increased DNA damage in the exposed animals. Planarian's behavioural endpoints were sensitive to TBT exposure showing clear dose-response relationships. This work aims at presenting methodologies that can be easily performed in laboratory assays while advocating the suitability of using freshwater planarians as an alternative for animal testing in ecotoxicological research. **Keywords:** freshwater flatworms; ecotoxicology; behavioural endpoints; regeneration

### 461

#### No effects of steroid androgen exposure during development on *Biomphalaria glabrata* reproductive physiology

A. Baynes, Brunel University / Institute for the Environment; S. Kaur, A. Lockyer, Brunel University; E.J. Routledge, Brunel University / Institute for the Environment; C. Jones, Central Queensland University / Medical and Applied Sciences; L. Noble, University of Aberdeen / School of Biological Sciences; S. Jobling, Institute for the Environment

A large number of environmental contaminants are thought to have endocrine disrupting properties, many of which elicit androgenic or anti-androgenic responses. Gastropod molluscs are proposed as an invertebrate model for toxicology testing of androgenic/anti-androgenic endocrine disrupting compounds, due to some similarities between their reproductive anatomy and that of mammals, together with evidence that endocrine disrupting chemicals can cause biological effects in these animals analogous to those seen in mammals. To test this hypothesis, we used the freshwater pulmonate snail, *Biomphalaria glabrata* for which various genetic tools and a draft genome have recently become available, to investigate the effects of two steroid androgens on the development of *B. glabrata* secondary sexual organs. Here we present the results of exposures to two androgens, 17 $\alpha$ -methyltestosterone and dihydrotestosterone under continuous flow-through conditions throughout embryonic development and up to sexual maturity. Morphological, histopathological and differential gene expression analysis (Suppression Subtractive Hybridization, SSH) revealed no significant differences between exposed and control tissues from snails developmentally exposed to 17 $\alpha$ -methyltestosterone or dihydrotestosterone, suggesting that the snails did not respond to, and were not affected by, exposure to these potent vertebrate androgens. These results are consistent with the recent findings that *B. glabrata* genome does not possess an androgen receptor. The consequence of this finding is significant in the development of appropriate model organisms for toxicology and ecotoxicology and highlights the importance of having supporting molecular programs and mechanistically relevant endpoints for the proposed test species. It also suggesting more fundamental research into mollusc endocrinology is required, as currently there is still a significant lack of information with which to assess the risk of contaminants to molluscs in the aquatic environment.

### 462

#### The invertebrate pond snail *Lymnaea stagnalis*: a promising model in Environmental immunotoxicology?

P. Boisseaux, K. Abbaci, Irstea Lyon; S. Betoulle, Université de Reims; J. Garric, Irstea Lyon

Wildlife is exposed to multistresses (e.g. chemicals and microbiologicals). The immune system has a pivotal role in the health of organisms, particularly to clear pathogens. Many xenobiotics exert immunotoxicological features. The great pond snail *Lymnaea stagnalis* is ecologically relevant in Holarctic regions of the planet. It is an OECD gastropod model in ecotoxicology. This invertebrate possesses an innate-like immune system. Hemocytes are the circulating immunocompetent cells. The hemolymph collection is easy and non-invasive, which allows following markers individually with time-course evolution. First, we aimed at gaining more insights on hemocyte characterization. Flow cytometry evidenced three clusters of hemocytes. Microscopy images reported differences on cytoplasmic size and nucleus lobulation. Ultrastructures revealed intense activity with small granules. Two organelles were depicted: a lysosomal-like structure with spectacular fibril organization and a massive perinuclear accumulation. Cells exerted diverse surfaces smoothness and sailboat-like structures. Second, we assessed the intra/inter-individual variability of hemocyte concentration and viability. Plus, we questioned if the operation of mechanical hemolymph extraction had an impact on the hemocyte renewal stock. The hemolymph collection (up to 24h) had no significant effects on the hemocyte renewal stock, neither on their viability. Hemocyte concentration fluctuated per snail (over time) and between snails. Hemocyte viability was quite stable all the days tested. Snails that died during the

experiments can be individually tracked until so. Indeed, progressive decreases of both markers were clearly observed. They are promising indicators of snail's health. Last, we investigated the effects of a case xenobiotic: Etoposide. This anti-cancer drug is used worldwide. Etoposide induced a sharp drop of hemocytes at therapeutical-like concentrations [immunosuppression], whereas the density was increased at environmental realistic concentrations. Such phenomenon has been reported oftentimes in *L. stagnalis*; underlying mechanisms are not elucidated yet. Hemocyte viability decreased gradually along with increasing drug concentration. Phagocytosis activity remained unaffected. Further studies will look at the relationship between modulation of immunocompetence due to xenobiotics and *Darwinian fitness* endpoints to counterbalance the sensitivity of immunomarkers in the context of ecotoxicology.

#### 463

##### **Relationship between diuron biotransformation assessed by UPLC MS-MS and its embryo- and genotoxic effects in the Japanese oyster**

**D. Behrens**, Laboratory of Ecotoxicology; N. Tapie, ISM/LPTC - UMR5255 CNRS; P. Pardon, University of Bordeaux / UMR CNRS 5805 EPOC-LPTC; H. Budzinski, University of Bordeaux / UMR EPOC Equipe LPTC; J. Rouxel, IFREMER; T. Burgeot, IFREMER / BIOGEOCHIMIE ECOTOXICOLOGIE; F. Akcha, IFREMER / Laboratory of Ecotoxicology  
The oyster *Crassostrea gigas* is France principal shellfish aquaculture species but its production has been declining since the late 2000s due to recurrent summer mortality events. Although these episodes are believed to be multifactorial, recent studies have shown that oyster development is sensitive to pollutants such as herbicides. However, the mechanisms by which herbicides can affect oyster physiology remain unclear, as well as their biological fate once in the organisms. In this study, we compared the embryotoxic and genotoxic effects of the herbicide diuron and its known metabolites: DCPMU, DCPU and 3,4-DCA. A range of environmentally relevant concentrations (0.002-0.5 µg.L<sup>-1</sup>) was tested applying the embryo-larval bioassay for the embryotoxicity study and the comet assay for genotoxicity assessment. Co-exposures of the herbicides (diuron or metabolites at 0.5 µg.L<sup>-1</sup>) with a known antioxidant compound (ascorbic acid at 5-25 µM) were also realised to check ROS involvement in the toxicity. The ability of oyster to biotransform diuron was also investigated at different live stages (sperm, oocyte, trochophore larvae, adult). Microsomal incubations of subcellular fractions with diuron (1.17 and 11.7 mg.L<sup>-1</sup>) were performed and biotransformation products analysed by LC-MS-MS. Diuron significantly impaired embryo-larval development from 0.01 µg.L<sup>-1</sup>. Although in a lower extent, N-demethylated DCPMU and DCPU triggered similar significant alteration. Only the final degradation product 3,4-DCA did not show any embryotoxic effect. The embryotoxicity of diuron, DCPMU and DCPU were significantly reduced in the presence of the antioxidant scavenger, highlighting a role for ROS production in diuron toxicity. That is in accordance with the oxidative DNA damage observed during this study. Preliminary LC-MS/MS analysis showed that the different live stages have the potential to biotransform diuron into DCPMU and DCPU, although in different extent. ROS production could be a side-effect of biotransformation process.

##### **Nuclear receptors in the Pacific oyster, *Crassostrea gigas*, and their expression during early development.**

**S. Vogeler**, University of Exeter / College of Life and Environmental Science; T.S. Galloway, University of Exeter / Biosciences Department; B.P. Lyons; T. Bean, Centre for Environment Fisheries and Aquaculture Science / Environment and Animal Health

Molluscs represent the second largest phylum among the invertebrates and are characteristic features of aquatic and terrestrial habitats world-wide. They are under enormous risk from xenobiotic compounds in the environment through anthropogenic pollution, but little is known of the molecular mechanisms underlying these effects. Nuclear receptors are a superfamily of transcription factors important in key biological, developmental and reproductive processes. Several of these receptors are ligand- activated and through their ability to bind endogenous and exogenous ligands, are potentially vulnerable to xenobiotics. By mining the Pacific oyster (*Crassostrea gigas*) genome we revealed a highly diverse set of nuclear receptors showing 43 homolog members to most of the known *Drosophila* and human receptors. They include members of the NR0-NR5 subfamily, notably lacking any NR6 members. Homologues to known xenobiotic-vulnerable nuclear receptors in other invertebrates and vertebrates have been confirmed (e.g. retinoid and thyroid-like receptors). Conducted gene expression analysis of the *C. gigas* nuclear receptors during early developmental stages using quantitative real-time PCR indicates that many of these nuclear receptors are crucial during organogenesis and shell development. This data provides a deeper insight in nuclear receptor presence and function in mollusc species and suggests that any putative xenobiotic-receptor interaction could lead to serious effects on the oyster development. This will directly aid the development of ecological risk assessments and enhance protection of the environment.

## **Multistress in aquatic environments: the big picture (II)**

#### 465

##### **EcoImpact - Effects of Micropollutants from Wastewater Treatment Plants on Stream Ecosystems: Ecotoxicological and Chemical Evaluations in 24 Swiss Rivers**

**C. Kienle**; S. Birrer, Swiss Centre for Applied Ecotoxicology Eawag-EPFL; F. Deuber, Eawag Swiss Federal Institute of Aquatic Science and Technology; B. Ganser, Ecotox Centre CH; N. Homazava, B. Lüppli, Swiss Centre for Applied Ecotoxicology Eawag-EPFL; J. Mazenauer, Eawag Swiss Federal Institute of Aquatic Science and Technology; M. Reyes; S. Santiago, Soluval Santiago; A. Schifferli, Swiss Centre for Applied Ecotoxicology Eawag/EPFL; H. Singer, Eawag Aquatic Research; B. Spycher, Eawag Swiss Federal Institute of Aquatic Science and Technology; E. Vermeirssen, Eawag / Dept of Environmental Toxicology; C. Stamm, Department of Environmental Chemistry; I. Werner, Swiss Centre for Applied Ecotoxicology / Department of Anatomy Physiology and Cell Biology

Micropollutants are organic and inorganic substances, which occur in very low concentrations in surface waters. Even at these low concentrations, some of them can elicit effects on aquatic organisms. The aim of the project EcoImpact is to evaluate the effects of micropollutants originating from wastewater treatment plant (WWTP) effluents on stream ecosystems. The project combines chemical, microbiological, ecotoxicological and ecological evaluations in order to enable a comprehensive understanding of the river ecosystem processes. This paper focuses on a part of the project: the ecotoxicological and chemical evaluations. Several measurement campaigns were conducted in 2013 and 2014. In 2013 a screening of 485 micropollutants as well as laboratory and field bioassays were performed. At selected sites, feeding activity of amphipods (*Gammarus fossarum*) as well as the reproduction of water fleas (*Ceriodaphnia dubia*) were assessed. Additionally, effects on the photosynthesis and growth of single-celled green algae (*Pseudokirchneriella subcapitata*), estrogenic activity (Yeast Estrogen Screen), and neurotoxic effects (acetylcholinesterase inhibition assay) were evaluated in all samples. The 2014 assessment programme consisted of the chemical evaluation of 60 substances as well as an assessment of estrogenic activity, algal toxicity and neurotoxic effects. With regard to estrogenic activity and photosynthesis inhibition, the impact of the WWTP was obvious. 17β-Estradiol equivalent concentrations (EEQ) as well as diuron equivalent concentrations (DEQ) were mostly higher downstream compared to upstream of the WWTP. Similarly, a decreased amphipod feeding activity was detected at one of four sampling sites. A significantly decreased reproduction of *C. dubia* was detected at one of four sites as well. The applied methods proved to be well suitable for a chemical and ecotoxicological assessment of river water quality. In general, the contamination with estrogenic substances can be considered relatively low. The EEQs never exceeded the effect-based chronic environmental quality standard (Annual Average (AA) EQS) for 17β-estradiol (0.4 ng/L). However, in a majority of the evaluated rivers, the DEQ exceeded the AA-EQS for diuron (20 ng/L), partly already upstream of the WWTP. Future data evaluation will include a comparison with chemical and ecological data to complete the overall picture, and to draw further conclusions on the effects of micropollutants on stream ecosystems.

#### 466

##### **Data opportunities and challenges for assessing multiple stressors across scales in aquatic ecosystems**

**K.A. Dafforn**, University of New South Wales / Evolution and Ecology Research Centre; E.L. Johnston, University of New South Wales / Evolution and Ecology Research Centre; A. Ferguson, NSW Office of Environment and Heritage; C. Humphrey, Environmental Research Institute of the Supervising Scientist; W. Monk, Environment Canada; **S.J. Nichols**, University of Canberra / Institute for Applied Ecology and MDBFutures Collaborative Research Network; S.L. Simpson, CSIRO Land and Water / Centre for Environmental Contaminants Research; M.G. Tulbure, University of New South Wales; D.J. Baird, Environment Canada

Globally, aquatic ecosystems are under threat from a complex array of stressors, which vary in intensity and spatial scale. Monitoring and assessment of both marine and freshwater ecosystems have historically focused on collection of information on habitat quality, in terms of descriptions of physical and chemical conditions, often with associated observations on biological condition. The advent of high-performance computing systems, coupled with new earth observation platforms, has accelerated the adoption of remote sensing tools and geographical information systems (GIS) in ecosystem assessment. Their use in interpretation of scale-dependent ecological phenomena is an emerging area, and here we explore synergies with key areas of stress ecology. We introduce a conceptual framework that outlines a strategy for assessing multiple stressors across ecosystems using emerging sources of "big" data. We define big data as any collection of data sets so large and complex that it becomes difficult to process using traditional data processing applications. We critique a range of available big data types that could support models for multiple stressors and the assessment of their effects.

#### 467

##### **Effects of organic pollutants on oceanic photosynthetic function mediated by *Prochlorococcus***

**M. Fernandez-Pinos**, B. Pina, IDAEA-CSIC / Environmental Chemistry; m. vila-costa; M. Casado, Environmental Chemistry; S. Agustí, IMEDEA-CSIC; J.

Blasco, Inst. Ciencias Marinas de Andalucía / Instituto de Ciencias Marinas de Andalucía; I. Rivera-Duarte, SPAWAR Systems Center Pacific / Scientist; M. Estrada, ICM-CSIC; R.S. Lopes, Universidade de Aveiro / Departamento de Biologia CESAM; C. Sobrino, University of Vigo; J. Dachs, IDAEA-CSIC / Environmental Chemistry

We developed a simple and high-throughput amenable methodology to monitor the photosynthetic capability of *Prochlorococcus* in the field to study the effects of organic pollutants on the oceanic carbon cycle. The cyanobacterium *Prochlorococcus* is a major contributor of oceanic primary production and it is widely distributed in tropical and subtropical oceans. Moreover it is extremely sensitive to environmental stressors such as organic pollutants or UV radiation. Consequently, *Prochlorococcus* constitutes an excellent sentinel organism to evaluate the dependence of the photosynthetic function to environmental variables and anthropogenic impacts at middle latitudes. We selected two genes of *Prochlorococcus* as biomarkers of its photosynthetic capacity: *rbcL* (RuBisCo large subunit gene) and *psbA* (photosystem II D1 protein gene), and the reference gene, *rnpB* (RNA component of the RNaseP gene). *Prochlorococcus* high-light and low-light clades were analyzed separately. During the Malaspina circumnavigation (Dec. 2010 - July 2011) we measured the expression of the three genes in a total of 62 stations, in Atlantic, Indian, and Pacific oceans at three different depths: 3 m, deep chlorophyll maximum (DCM), and DCM+40 m. Concurrently, we analyzed more than 300 biological, physical and chemical variables, including the concentrations of diverse organic pollutants present in seawater. We also performed 13 experiments on board, that consisted in challenging DCM communities with either: 1) PAH mixture (700ng/mL), 2) organochlorine pesticide (OCIP) mixture (500ng/mL) or 3) complex mixture (CM) of organic pollutants from concentrated seawater (x10). We measured the bioavailable organic pollutant concentrations after 0.5 and 24 h of treatment, and the changes in the expression of *Prochlorococcus rbcL* and *psbA* genes at 0.5, 2, 6 and 24 h. We found a higher toxicity of CM compared with the other two mixtures, that only included a few organic pollutants. CM caused a significant downregulation of both analyzed genes after 2 h of exposure. We also observed a decrease of *psbA* expression in communities treated with PAHs after 0.5 and 24 h. In addition, these experiments demonstrated a differential effect of the three tested mixtures along the time. Respect to field measurement, *rbcL* and *psbA* expression resulted to be dependent on the location and correlated with different environmental variables, that included negative correlations with some organic pollutants.

#### 468

##### **Scale-hierarchic approaches to multiple stressors over French running waters**

K. Van Looy, B. Villeneuve, J. Piffady, Irstea Lyon / UR MALY  
We present a scale-hierarchic predictive modelling and risk-based framework for river ecosystem assessment integrating potential intervening stressor processes. It considers ecosystem functions and impairments in physico-chemistry, hydromorphology and ecology. For the risk-based approach, the pesticide model will be shown as illustration. The predictive models are constructed based on stream data for benthic macroinvertebrates, diatoms and fish, combined with stressor variables from the three hierarchic scale-levels of catchment functioning. The models run successfully on data for the three types of stressors, respectively present at catchment, reach and local scale: land use pressure, hydromorphological pressure and physico-chemical pressure. The Arpeges (Risk Analysis of Pesticides for Surface Water management) model takes soil and molecule properties into account to provide a unified model of contamination risk over the French national territory. It provides a robust tool for the French Water Authorities in assessing the status and the risk of failing to meet the environmental objectives. The model translates catchment-scale descriptors, related to main ways of pollution transfer, chemical component properties and pesticide use, into indicators of seasonal acute and chronic pollution magnitudes.

#### 469

##### **Assessing the ecological impacts of trace organics using a weight of evidence framework**

J.M. Daley, University of Michigan / School of Natural Resources and Environment; A. Burton, University of Michigan / School of Natural Resources Environment; J.R. Wolfe, LimnoTech, Inc.; D. Bradley, C. Turner, LimnoTech; D. Macavoy, University of Cincinnati

The complexity of ecosystems often makes it difficult for community impact assessments to detect the ecological effects of anthropogenic activities and to relate these changes to stressor exposure. While many biomonitoring approaches can measure environmental impacts on biological communities they often fail to establish a strong stressor-causality link. A weight of evidence (WOE) approach can be a useful tool in establishing a causal link between a stressor and biotic life impairments by utilizing a combination of physical, chemical and biological characterizations. We apply a WOE approach to assess the potential of trace organic compounds (TORC) risks (including personal care products and pharmaceuticals) at multiple field demonstration sites. Sites were selected following an initial impact assessment of each location (ie. having known aquatic impairments, stressors aside from TORCs, and WWTP inputs). A rigorous sampling method was developed to account for multiple lines of evidence and includes an assessment of the chemical loadings, water quality parameters (ie. NH<sub>3</sub>, DO, metals, suspended solids, pH, total and dissolved organic carbon), habitat quality,

benthic macroinvertebrate and fish community metrics, endocrine disruption and other biochemical and genomic responses using in situ caged fish, and an in situ Toxicity Identification Evaluation (iTIE) approach. This iTIE separates out TORC related toxicity from other potential toxics (ie. ammonia, nonpolar organics, metals). The use of this WOE framework in combination with robust models, provides a powerful tool in establishing a causality link and in assessing whether TORC concentrations from effluent discharges and their receiving waters are likely to cause an adverse effect on aquatic populations and whether the observed impacts on aquatic populations are likely caused by TORCs and/or other stressors.

#### 470

##### **Evaluating relations between stressors and ecological endpoints at the regional scale**

P.C. Van Metre, U. S. Geological Survey / Texas Water Science Center; M.P. Babut, Irstea / Water; M. Liess, UFZ Center for Environmental Research / Department of SystemEcotoxicology  
Relations between environmental stressors in streams—contaminants, nutrients, streamflow, temperature, and habitat—and ecological communities are highly complex. Effects of stressors on biological conditions often are evaluated in local-scale field studies, where processes can be monitored, or in laboratory experiments, where conditions can be manipulated to identify the cause(s) of impairment. However, results of local-scale studies are not necessarily applicable to other locations or able to describe large-scale patterns, and it is often difficult to extrapolate from the laboratory to the field. At the opposite end of the spatial scale from local-scale studies are regional-scale studies that include measurements of stressors and ecological conditions at large numbers of sites across ecologically-similar regions with the goal of empirically modeling stressor-condition relations on a regional basis. Such studies can potentially provide the statistical power necessary to evaluate the effects of multiple stressors on ecological communities, and develop models to predict ecological conditions at unsampled sites. Regional assessment approaches of streams will be illustrated by using results from the U.S. Geological Survey Regional Stream Quality Assessment of 100 sites in the Midwestern United States, an assessment of pesticide effects on macroinvertebrate communities using 663 sites across Germany, and development of a stressor-based ecological model using 1,100 sites across France.

## **Effects and accumulation process of organic pollutants and metals in bacteria, phytoplankton and zooplankton**

#### 471

##### **Accumulation and trophic transfer of POPs in plankton in the Gulf of Lion, Western Mediterranean**

J.A. Tronczynski, IFREMER / RBE; C. Tixier, IFREMER; M. Harmelin-Vivien, F. Carlotti, MIO

The present study focuses on the accumulation and trophic transfer of persistent organic contaminants (PCBs, PBDEs, OCPs and PAHs) at the primary trophic levels (autotrophs and heterotrophs) in the Gulf of Lion (GoL), Western Mediterranean. The concentrations of selected POPs in plankton were generally higher in the eastern part of the GoL i.e. at the stations under direct influence of urban center of Marseille and of the Rhône River. The results show that levels of PCBs and PBDEs in plankton in the GoL are spatially influenced by the distance from contamination source and that marine plankton seems to be able to assimilate rapidly POPs compounds at the stations near contaminants source. The relationship between POP concentrations and size class of plankton and plankton  $\delta^{15}\text{N}$  signatures is compound, seasonally and spatially depended. However, the highest concentrations of POPs were determined in the lowest fraction 0.7 - 63  $\mu\text{m}$  of plankton. This fraction show significantly different  $\delta^{13}\text{C}$  and  $\delta^{15}\text{N}$  signatures from other plankton fractions, indicating high contribution of bacteria / nano and picoplankton to organic carbon pool in these samples. The role of this fraction in contaminants transfer within planktonic communities is yet poorly documented. Furthermore, our results indicate that prey-predator contaminant transfer is difficult to clearly distinguish within planktonic food-webs. The higher zooplankton size classes are composed of organisms with different diets, including herbivores, carnivores and detritivores, prone in addition to adapt their diet to the quantity of available resources. Additionally, in field samples, size class and isotope signatures do not necessarily reflect a prey-predator relationships, and complex ecology and ecosystem interactions within plankton communities. Thus, evidencing and quantifying contaminant biomagnification in plankton may be a difficult task, especially in the coastal environments. The full data and results of this study focused on the trophic transfer of organic contaminants in plankton will be further discussed and presented.

#### 472

##### **Role of the Accumulation in Plankton on the Cycling of Polycyclic Aromatic Hydrocarbons in the Global Tropical Oceans**

B. Gonzalez-Gaya, Institute of Environmental Assessment and Water Research / Environmental Chemistry; M. Fernandez-Pinos, IDAEA-CSIC / Environmental Chemistry; C.J. Galbán, Sustainability Research Centre / Department of Ecology and Biodiversity; B. Jimenez, IQOG-CSIC / Instrumental Analysis Environment; J. Dachs, IDAEA-CSIC / Environmental Chemistry

Polycyclic Aromatic Hydrocarbons (PAHs) are organic pollutants generated during incomplete combustion of fossil fuels and organic matter. They cause carcinogenic and toxic effects in biota, and have been proved to be harmful for ecosystems. Moreover, PAHs are ubiquitous in the environment and show increasing levels in some regions due to growing anthropogenic sources. The global ocean has been pointed to hold a strong degradation capacity for these compounds, but it is still necessary to assess the entry and fate of PAHs in the ocean and how it is coupled to the adsorption, bioaccumulation and biodegradation processes occurring in the surface oceans. Atmospheric deposition is the main vector for the entrance of semivolatile organic compounds to the global oceans through two different inputs; dry deposition and diffusive air-water exchange. Dry deposition fluxes have been measured, and diffusive fluxes have been estimated from air and water concentrations, for all sub- and tropical oceans (35°N- 40°S) during the Malaspina 2010 circumnavigation cruise in the Atlantic, Pacific and Indian oceans. Water and plankton concentrations of these compounds during the same sampling campaign were also measured. Low molecular weight PAHs, are prone to be diffused and degraded in the marine euphotic area, meanwhile high molecular PAHs (the more recalcitrant and toxic) enter into the ocean mainly attached to the aerosol and rapidly adsorb to plankton due to their lipophilicity. Therefore, a complex feedback is established between depositional fluxes and degradation/bioadsorption processes and will be reviewed in this oral platform. Water-plankton equilibria and other physico-chemical processes in the water column (like PAHs "dilution effect" with high plankton biomasses) will be discussed as well. These results are the most extensive data set available for the global ocean and provide evidence of the important physical and biological controls on PAH occurrence and cycling in oceanic regions.

#### 473

##### **Induced tolerance and altered microbial community composition after exposure to low concentrations of PAHs**

F. Lindgren, Shipping and Marine Technology; I. Dahllof, University of Gothenburg / Department of Biological and Environmental Sciences; H. Landquist, Chalmers University of Technology; I. Hasselöf, Chalmers University of Technology / Department of Shipping and Marine Technology  
When biotic communities are exposed to non-lethal concentrations for long periods of time there is a possibility that they develop tolerance to the pollutant. In that case the negative effects might be hidden through adaptation to the polluted conditions, hence the communities appear healthy. Polycyclic aromatic hydrocarbons (PAHs) are worldwide pollutants that lead to lethal effects in high concentrations and sub-lethal effects in low concentrations. The tendency for microbial communities to develop tolerance to PAHs is not well studied. In this study the ability for marine microbes to develop tolerance to PAHs was examined in a 90-day experiment. Treatments with an increase in PAH levels of 1.6 (H) and 0.3 (L) times were compared to control sediment. Day 30, 60 and 90 the microbes were exposed to a new addition of PAHs in a short-term toxicity test to detect possible tolerance. Ability for nitrification and denitrification by the microbial community was used as endpoints. Molecular analysis of the microbial communities was performed to detect possible differences in proportions of nitrifying bacteria compared to total bacterial abundance between treatments and control. We here present novel data showing an induced tolerance in nitrifying microbial communities to PAHs after 60 and 90 days. EC10-values for inhibition of nitrification were significantly higher in L after 60 days and both treatments after 90 days compared to control. Furthermore, the developed tolerance led to less productive communities when unexposed. It was also shown that the induced tolerance produced dissimilar ratios of ammonium oxidizing bacteria vs. total bacterial density between treatments and control, indicating that development of the tolerance had varying pathways in the two treatments. The results from this study have implications on field studies or environmental monitoring programs of long-term oil and PAH contaminated sites. The potential development of tolerance must be taken into account and tested for when evaluating marine microbial health in oil contaminated areas, as tolerant communities can be wrongly mistaken for healthy communities. In addition, changed ratios of nitrifying microbes can alter the capacity for ammonium oxidizing in benthic marine sediments.

#### 474

##### **Bacterial community structure and biogeochemical activity in an aquifer contaminated with pesticides**

a. Mauffret, BRGM / Environmental biogeochemistry and water quality; N. BARAN, M. Charron, C. Joulain, BRGM  
Our objective was to assess the effect of cocktails of pesticides on groundwater microbial abundance, community structure and their nitrate reducing activity. We used two complementary approaches: a 2-year monitoring at a catchment level (Ariege alluvial plain, France) and microcosm with groundwater collected in 2 parts of the aquifer and then spiked with selected herbicides having a high occurrence in this aquifer, atrazine (ATZ), desethylated atrazine (DEA) and ATZ+DEA. Abundance of the universal marker (16S rRNA) and of nitrate-reducing bacteria (*narG* and *napA*) was assessed by quantitative PCR (qPCR). Diversity was assessed using fingerprinting technic, CE-SSCP (Capillary Electrophoresis-Single Strand Conformational Polymorphism). Pesticides in water were analyzed by LC-MS/MS following an on line-solid phase extraction, and samples for anions and cations were analyzed by ion chromatography. Preliminary results of the

microcosm experiment show that biodiversity was higher in water historically contaminated than in pristine-like water and remained higher under laboratory incubations with ATZ, DEA or ATZ+DEA concentrations. Pesticide concentrations in the water historically contaminated often exceeded the legal EU threshold for groundwater and drinking waters (2-year mean:  $0.09 \pm 0.01 \mu\text{g ATZ/L}$ ,  $0.43 \pm 0.06 \mu\text{g DEA/L}$  ( $n = 23$ )). On the other side, during microcosm incubation, biodiversity decreased when spiked-ATZ, -DEA or -ATZ+DEA increased from 1 to  $10 \mu\text{g/L}$ . The undergoing analyses of the two-year monitoring at the catchment level will enable to refine boundaries within this complex relationship between biodiversity and pesticide contamination. ATZ, DEA or ATZ+DEA exhibited similar effect on the microbial community. The nitrate reducing bacterial community strongly decreased during the microcosm experiment. *In situ* samples are expected to clarify the effect of pesticide contamination on bacterial nitrate reducing activity and the possible risk of nitrate accumulation and/or the possible risk of inhibition effect of nitrate on pesticide biodegradation. Biomass was similar in all conditions, suggesting that this is not a sensitive endpoint to assess water quality. This study has the potential to provide sound-based arguments to be considered when improving the current strategy to manage water quality as well as when proposing end point to monitor the microbial community in the biodiversity objective under the European water directive framework.

#### 475

##### **Effects of copper and herbicide mixtures on phytoplankton community from the Charente river estuary**

S. Stachowski-Haberkorn, IFREMER / BIOGEOCHIMIE ECOTOXICOLOGIE; S. Guesdon, C. Béchemin, L. Haugarreau, D. Ménard, J. Rouxel, IFREMER; N. Coquillé, IRSTEA Bordeaux Ifremer Nantes EPOC (LPTC); C. Vérité, G. Charpentier, J. Seugnet, J. Grizon, J. Chabirand, C. Brach-Papa, J. Chiffolleau, D. Auger, E. Rozuel, IFREMER; C. Lambert, CNRS; P. Soudant, Institut Universitaire Européen de la Mer (IUEM) Université de Bretagne Occidentale (UBO); L. Quiniou, B. Beker, Université de Bretagne Occidentale; A. Jadas-Hécart, P. Communal, Université Angers  
This field study was conducted in the Charente river estuary (Marennes-Oléron bay, France). The main goal was to assess the impacts of copper and herbicides on phytoplankton communities. Physical, chemical (nutrients, metals and pesticides) and biological (phytoplankton community) parameters were monitored in the field during three years, from 2011 to 2014. In 2012 and 2013, field sampling was coupled with experimental exposure of phytoplankton communities to copper and to an herbicide cocktail, after transportation to the lab: the effects were assessed using photosynthesis endpoint and cellular densities. This study described the framework of Charente estuary contamination with pesticides: herbicides glyphosate and metolachlor were almost permanently detected at the most upstream station. The most elevated concentrations were noticed during the first part of each year. Samples from spring and early summer also exhibited other herbicides: dimethenamid, acetochlor, bentazon, mesotrion, metamitron. Phytoplankton dynamics in the natural environment was studied as a whole but also on community subsets: micro-, nano-, pico-phytoplankton and cyanobacteria *Synechococcus* sp.. The most influent driver on the whole phytoplankton community abundance was shown to be temperature, related to seasons; however other variables were also significant drivers for the community subsets. The analysis model used highlighted an abnormal low abundance period for *Synechococcus* sp. during spring 2012. At the same time, a massive freshwater discharge that brought pesticides was also noticed: although this event was not identified as responsible for this drop, it might have weakened the communities. The laboratory experiments showed a marked sensitivity of phytoplankton communities that were exposed to copper in 2012: especially, *Synechococcus* sp. were shown to be impacted by copper, at environmental concentrations at the  $\mu\text{g.L}^{-1}$  level. The herbicide cocktail used in 2012 (glyphosate, metolachlor and mesotrion) induced no significant effect on phytoplankton communities, whatever the concentration tested and the season. In 2013, the modified cocktail (glyphosate, S-metolachlor, dimethenamid and metamitron) led to significant but slight effects on photosynthesis with no variation related to stations or seasons. Tests run from spring to autumn during two years did not demonstrate phytoplankton sensitivity towards the tested herbicides at environmental relevant concentrations.

#### 476

##### **Cestode parasitism increases resistance to Arsenic poisoning in brine shrimps**

m.I. sanchez, CSIC / Wetland Ecology; I. Pons, EBD-CSIC / Wetland Ecology; C. Petit, EBD-CSIC; M. Martinez-Haro, IMAR-CMA (Marine and Environmental Research Centre / Department of Life Sciences; M.A. Taggart, Environmental Research Institute / Environmental Research Institute; A.J. Green, EBD-CSIC / Wetland Ecology  
In nature virtually all aquatic organisms are affected by both pollution and parasites, but few studies exist on the interactions between these two factors in aquatic environments (an emerging field of research known as "Environmental Parasitology"). Special interest has been devoted to the effect of both factors as stressors on the health of aquatic organisms. In the present study we performed a series of acute toxicity tests with Arsenic in the brine shrimp *Artemia parthenogenetica* infected by avian cestode parasites and uninfected individuals, and showed for the first time that parasites increase resistance to heavy metal exposition. We also showed that infection characteristics (prevalence of the

flamingo parasites *Flamingolepis liguloides* and that of Grebe parasite *Confluarina podicipina*) affected the degree of resistance to As. An increase of 4°C temperature as expected by climate change scenarios strongly decreased resistance to Arsenic in both groups, with a stronger effect in uninfected individuals. We explain our results on the basis of the effect of parasites on the canthaxantins levels of hosts, which are known to have a potent antioxidant and detoxification effect. Our results highlight the importance of considering the infection level of aquatic organisms in ecotoxicological studies to obtain reliable conclusions.

## Innovations in environmental analytical chemistry: the quest for pollutants using target and non-target approaches (II)

### Profiling of emerging contaminants in drinking water using passive samplers

A.K. Zenker, University of Appl. Sc. Northwestern Switzerland / Institute of Ecopreneurship; T. Hettich, G. Schlotterbeck, University of Applied Sciences Northwestern Switzerland / Institute of Chemistry and Bioanalytics

Anthropogenic pollution is one of the major problems which affect quality of potable water. Potentially a broad spectrum of chemicals is expected to appear, but it is not feasible to analyse all groups of chemicals in a simple targeted method. Water sampling is a limiting factor as it is performed mostly by grabbing water at defined time points providing residue data only for the moment the sample was taken. Many emerging contaminants are therefore not detected in the water sample. In contrast passive integrative samplers collect a broad range of chemicals over one or two months. The aim of this study was to establish a workflow for a non-targeted profiling of emerging contaminants in drinking water in which polar organic chemical integrative sampler (POCIS) were combined with liquid chromatography coupled to high resolution mass spectrometry (LC-HRMS). Beside our routinely identified micropollutants in target screening on a HPLC-ESI-QqQ-MS/MS aliquots of POCIS extracts were also measured in non-target screening on a HPLC-ESI-Q-TOF-MS in positive and negative mode. The separation was done on a Zorbax Eclipse Plus C8 column in gradient. Mass spectra were acquired in scan mode from 100-1000 m/z and with 0 CID voltage. The scan data's were matched against in-house compound library to annotate substances in the extract. For further comparison of different sampling sites the data's were processed with statistical analysis (Agilent Mass Profiler Professional, 12.6). Significant separating features identified from principal component analysis were selected to create a targeted hit list. In the second level the extracts were analysed with the hit list in fragmentation mode by 10, 20 and 40 CID V to obtain structural information. These MS/MS spectra's were matched against focused databases to identify compounds. In addition, it was possible to perform de novo identification by try and error. The complexing agent, Ethylenediaminetetraacetic acid, the halogenated hydrocarbon, Tetrachloroethene, and radiocontrast agents Iopamidol and Ioxitalamic acid, were detected in concentrations higher than 10 ng/L.

478

### Purification, characterization and ecotoxicity of disperse azo dyes

G.d. Umbuzeiro, FACULTY OF TECHNOLOGY -UNICAMP / LEAL; M. Szymczyk, M. Li, Y. Chen, NCSU / College of Textiles; J.A. Vendemiatti, A.F. Albuquerque, University of Campinas; A. Santos, FACULTY OF TECHNOLOGY UNICAMP / LEAL Laboratory of Ecotoxicology and Environmental Microbiology; B.S. Maselli, SCHOOL OF TECHNOLOGY UNICAMP / LEAL Laboratory of Ecotoxicology and Environmental Microbiology; F. Kummrow, Universidade Federal de São Paulo; N.R. Vinuesa, NCSU / College of Textiles; H. Freeman, North Carolina State University

Although tons of disperse azo dyes have been used worldwide, little information regarding their ecotoxicity is available. Because dyes are subject to regulation under the REACH program there is an urgent need for ecotoxicity data. However testing disperse azo dyes is not easy. They are not readily found as pure compounds, they possess low water solubility, and it is not easy to prepare aqueous dye solutions devoid of precipitates or agglomerates. The objective of this work was to purify and chemically characterize four disperse azo dyes and test them in aqueous solution for acute toxicity with the microcrustacea (*Daphnia similis*). Four dyes were selected, CI Disperse Red 13, CI Disperse Blue 291, CI Disperse Blue 373 and CI Disperse Violet 93. Purification of the dyes was performed by flash column chromatography using silica gel. The best conditions for separation were selected after thin layer chromatography (TLC) experiments, using different solvent combinations and the ones that presented the best separation were used for column purifications. Purity was verified by HPLC/DAD (Waters) and melting point (Fisher-Johns apparatus) measurements and structures were confirmed by Nuclear Magnetic Resonance (NMR) spectroscopy using a Bruker 500 MHz instrument and by high resolution tandem mass spectrometry (MS/MS) on an Agilent 6520 quadrupole-time-of-flight (QTOF) equipped with an electrospray ionization (ESI) source. Dyes were dissolved in 0.05% DMSO then diluted in testing water. Acute toxicity testing was performed with *D. similis*. EC50 values were calculated using the Trimmed Spearman-Kärber method. Column purification was successful, with a minimum dye purity level of 97.31% and NMR and MS results were fully consistent with the chemical structure of each dye. CI Disperse Red 13 showed an EC50 of 53.8 µg/L ± 6.5. The other dyes did not cause immobility at the concentrations below water solubility. Tests with other trophic levels are being conducted, using fish embryo

test and algae, to obtain sufficient data to calculate predicted no effect concentrations (PNEC). **Acknowledgement:** The authors thank FULBRIGHT Scholar/CAPEs and FAPESP Thematic Project 2008/10449-7

### Advances in trace detection, quantification, and partitioning property estimation of bioaccumulative pollutants with GCxGC

J.S. Arey, Architecture Civil and Environmental Engineering; S. Samanipour, EPFL; D. Nabi, Masdar Institute / iWater; P. Dimitriou-Christidis, EPFL, Switzerland / LMCE, IEE; J. Gros, LMCE

Evolving formulations of technical products continue to introduce new halogenated chemicals into the environment that remain un-evaluated for their bioaccumulation potential, persistence, and toxicity. These chemicals may be overlooked by existing analytical techniques that must detect and quantify trace analytes despite substantial background signal arising from matrix. Additionally, conventional sample clean-up steps, often employed to decrease signal from matrix, may remove analytes of interest. Comprehensive two-dimensional gas chromatography, or GCxGC, is increasingly recognized as an effective analytical tool for separating complex mixtures of nonpolar pollutants. However the very rich signal data produced by GCxGC is challenging to analyze and remains largely under-exploited. In particular, limited efforts have been made to detect and quantify trace target analytes or conduct suspect screening with GCxGC, in real environmental samples. I will report on several recent advances in our laboratory, including: (i) improved detection, quantification, and tracking of overlooked halogenated pollutants at trace levels in environmental samples by GCxGC coupled to micro-electron capture detector (mECD), including an evaluation of matrix effects; (ii) high selectivity and decreased detection limits for both target and suspect halogenated pollutants by use of GCxGC coupled to high mass accuracy electron-capture negative chemical ionization – time-of-flight mass spectrometry (ENCI-TOFMS), a prototype instrument; and (iii) estimation of environmental partitioning properties of nonpolar analytes, based on their GCxGC retention times, which then enables rapid assessment of nonpolar analyte environmental behavior and bio-partitioning. Application of these techniques successfully elucidates several less-studied halogenated pollutants that occur in the aquatic environment and that warrant prompt investigation.

### LC-HRMS and GCxGC-TOF-MS: two complementary tools for screening of organic pollutants in river water and evaluation of treatment efficiency

L. BARRITAUD, VEOLIA Recherche et Innovation (VERI); C. Tondelier, V. Ingrand, VEOLIA Recherche et Innovation; S. THIBERT, SEDIF

Evaluation of water contamination whether it be river water or drinking water is traditionally performed with targeted analyses that measure a limited number of well known molecules usually regulated. Even if these analysis are compulsory they only give a restricted view of pollutants in water samples. New approaches are necessary to identify emerging compounds and evaluate the global quality of water. With that focus, a screening methodology using two complementary analytical techniques was developed by VERI. Apolar to semi-polar molecules are extracted with the sensitive Stir Bar Sorptive Extraction (SBSE) and analysed by in-line thermal desorption and comprehensive two-dimensional gas chromatography coupled with time of flight mass spectrometry (GCxGC-TOF-MS). Semi-polar to polar compounds are extracted with a large scale Solid Phase Extraction (SPE) protocol and analysed on a liquid chromatography coupled with a LQT-Orbitrap high resolution mass spectrometer (LC-HRMS). Organic pollutants are identified thanks to the commercial NIST database and to homemade databases containing more than 3000 compounds for GCxGC-TOF-MS and 1000 compounds for LC-HRMS. In cooperation with the SEDIF (public committee handling the drinking water production and distribution in the French Ile-de-France area), three river waters and several samples collected along one drinking water treatment plant are analysed with the mentioned screening methodology. According to samples, between 23 and 39 compounds are identified by GCxGC-TOF-MS in river water, this number is much higher with LC-HRMS (between 113 and 151 molecules). The complementarity of techniques is well proven as only 7 molecules are identified by both techniques. Compounds are mainly pharmaceuticals and pesticides but industrial contaminants are also were represented. Their proportion is quite stable in the three rivers. Drinking water treatment steps shows a good efficiency to remove organic compounds as 93% of the detected molecules in the river are strongly decreased by treatment. All categories of compounds are well eliminated, but pharmaceuticals detected by LC-HRMS seem to be particularly well suppressed during the process.

### Accurate Mass Spectrometry as a Tool for Characterization of Complex Lysimeter Leachate Samples

L.H. Hand, Syngenta Limited / Product Metabolism; S.J. Marshall, Syngenta Ltd / Product Safety; M. Saeed, Smithers Viscient; M. Earll, Syngenta Ltd / Product Safety; S. Hadfield, K. Richardson, Syngenta Ltd / Product Metabolism

Lysimeter studies are used to identify and quantify metabolites which have the potential to leach to groundwater. As these are model systems, the apparent metabolic profile of leachate samples is often much more complex than would be expected in true groundwater samples. This is particularly true for S-metolachlor,

which has a complex metabolic pathway, with many opportunities for transient intermediates. Quantification of the radioactivity in the leachate suggests that >100 radioactive components are present at concentrations of >0.1 µg/L. According to SANCO guidance, any of these components which are true metabolites of S-metolachlor must be identified in order to assess them for relevance. However, it is not possible to identify all metabolites within the sample conclusively, as there is insufficient metabolite mass in the sample for the NMR analysis that would be required. Recent advances in accurate mass spectrometry allows innovative screening approaches to characterize the content of complex leachate samples to a higher degree than previously possible. Leachate from a lysimeter study was screened for accurate masses (±5 ppm) corresponding to over 400 “theoretical” metabolite structures (permutations and combinations of the known functionality in metabolites previously identified in regulatory studies and published literature). Radio-HPLC analysis was also performed to allow quantification. “Theoretical” metabolites which were not present at >0.1 µg/L were then removed from the metabolite list. Iterative interrogation of the LC-MS data (along with chemical characterization of the leachate) was also conducted to allow further refinement of the “hypothetical” metabolite list to a shorter “plausible” metabolite list. These refinement steps resulted in a smaller list of 130 “plausible” metabolites representing a comprehensive description of the most likely metabolites present. Each was then assigned to a chemical cluster based on the functional groups present and a Principal Component Analysis model was developed based on molecular descriptors to visualise the entire “chemical space” and validate the assignment of metabolites to clusters. This characterization and PCA validation can assist with the selection of exemplar metabolites, for assessment according to the SANCO relevance guideline, which represent the leachate as a whole.

#### **Suspect screening of REACH's high production volume chemicals in environmental samples**

T.L. ter Laak, KWR; R.M. Sjerps, KWR Watercycle Research Institute / Chemical Water Quality and Health; D. Vughs, T. van Leerdam, KWR Watercycle Research Institute; T. Traas, E. Rorije, National Institute for Public Health and the Environment RIVM; A. van Wezel, KWR Watercycle Research Institute / Chemical Water Quality and Health  
Chemicals' legislation in the European Union aims to control risks to humans and the environment to ensure safe use of chemicals. Currently, the assessment of chemicals is based on the ratio of predicted environmental concentrations (PEC) and predicted no effect concentrations (PNEC). The objective of this study is to test if and how broad screening analyses of environmental samples can be applied to provide additional information on occurrence of chemicals for further evaluation or risk management. Hereto, broad screening data of environmental samples obtained with liquid chromatography coupled to high resolution accurate mass spectrometry were matched with 2402 chemicals with 1846 unique elemental compositions (suspect screening). The selected chemicals had production volumes of 100-1000 tons or were part of priority lists due to their persistence, bioaccumulation or toxicity (PBT) or carcinogenicity, mutagenicity or reproductive toxicity (CMR). The selected samples consisted of nine surface waters (2 large rivers, 3 small rivers, 3 harbours and 1 canal) and effluents of wastewater treatment plants (8 communal effluents, 4 industrial 4 airport effluents) all sampled in spring and summer of 2014. The suspect screening approach resulted in 402 matching elemental compositions in effluents and surface water samples. The matching elemental compositions of surface water samples are qualitatively and quantitatively different from the effluents. As expected, both the number of chemicals (factor 1.5 to 10) and the number of chemicals (factor 2 to 20) was lower in surface waters, compared to the effluents. Furthermore, it was observed that effluent from industry is distinctively different from both airport and communal effluents (Figure 1), and that patterns of small rivers impacted by communal effluents are similar to communal wastewater effluent samples. Only elemental compositions (masses) of chemicals were matched, chemicals could not be identified. Nevertheless, the applied suspect screening can (1) guide further evaluation of chemicals by triggering in depth study of REACH dossiers as delivered by industry as well as (2) providing a selection of chemicals to be identified. Thereby suspect screening can support risk assessment and management of these high production volume chemicals and guide monitoring.

#### **Evaluating the potential of bacterial biodegradation of sulfonamides to improve wastewater processing**

B.A. Kolvenbach, University of Applied Sciences and Arts Northwestern Switzerland / Institute for Ecopreneurship; B. Ricken, University of Applied Sciences Northwestern Switzerland / Institute for Ecopreneurship; P.J. Reis, A.C. Reis, Faculdade de Engenharia da Universidade do Porto / Laboratório de Engenharia de Processos Ambiente Biotecnologia e Energia; C.M. Manaia, CBQF Centro de Biotecnologia e Química Fina; O.C. Nunes, Faculdade de Engenharia - Universidade do Porto / LEPAE Laboratório de Engenharia de Processos Ambiente Biotecnologia e Energia; P.F. Corvini, University of Applied Sciences and Arts Northwestern Switzerland (FH NW)

Antibiotic residues have been detected in wastewater worldwide. Sulfonamides are among the most prescribed antibiotics in human and veterinary medicine. Following intake, they are mainly released without modifications. The presence of antibiotic residues in wastewater has been shown to correlate with the prevalence of antibiotic resistant bacteria. Hence, measures to reduce the load of these chemical and biological micro-pollutants are needed if the reuse of wastewater is envisaged. Up to now, advanced chemical oxidation methods have been shown to efficiently remove antibiotic residues from wastewater. However, biological degradation systems are described as being cost effective. However, with the exception of beta-lactamases, the information on the enzymatic cleavage of antibiotics is scarce. Up to now, only few sulfonamide degrading bacteria have been isolated, most of which were only found recently. *Pseudomonas psychrophila* strain HA-4 (Jiang *et al.* 2014), *Microbacterium* sp. strain BR1 (Ricken *et al.* 2013) and *Achromobacter* sp. strain PR1 (Reis *et al.* 2014) are among them. The present study is focused on these last two phylogenetically distant bacteria (of the phyla of *Actinobacteria* and *Proteobacteria*, respectively). Both strains, isolated from wastewater, are resistant to sulfamethoxazole (SMX), harboring genes encoding sulfonamide resistance (*sulI* gene). They release 3-amino-5-methylisoxazole as a dead-end-metabolite during SMX degradation. Furthermore, besides SMX, both can degrade several other sulfonamides, with the release of 3-amino-5-methylisoxazole as metabolite resultant of sulfamethoxazole breakdown. A comparison of the sulfonamide degradation pathway in these two phylogenetically distant bacteria can give first insights into the evolution of this rare biodegradation process. These bacteria or their enzymes can be valuable bioremediation tools contributing to improve waste water treatment processes in respect to sulfonamide removal. On the other hand, it is also important to determine the role of this degradation mechanism in the spread of antibiotic resistance in order to design strategies that minimize the risk of its dissemination. **References** Jiang B, *et al.* 2014. #### **Tuning Microbial Function to Transform Micropollutants during Managed Aquifer Recharge and Engineered Biofiltration**

J.E. Drewes, Technische Universität München / Chair of Urban Water Systems Engineering  
Attenuation of micropollutants during managed aquifer recharge (MAR) is mainly caused by microbial transformation. Though the underlying mechanisms and selective variables that determine biotransformation are not yet well understood, prior work has revealed that oligotrophic conditions resulted in a more diverse microbial community, which can feature the ability to transform less easily biodegradable micropollutants [1-5]. The aim of this study was to investigate how these factors could be implemented in new treatment strategies for managed aquifer recharge with recycled water to fully utilize the metabolic potential of the microbiome to transform micropollutants. To facilitate the development of these new approaches, we paired removal studies of select micropollutants in controlled laboratory-scale systems and full-scale MAR sites, state-of-the-art chemical measurements (LC-MS/MS) with Illumina MiSeq sequencing of small subunit ribosomal RNA gene transcripts (rRNA). Moderately degradable compounds were studied under two carbon feed conditions: 0.17 mg/L BDOC and 4.16 mg/L BDOC. These results confirm that carbon-starving conditions characterized by low BDOC improves removal efficiency of micropollutants. The metabolic capabilities of microbiome involved in biodegradation were significantly promoted under lower BDOC concentration and higher humic acid content. Cytochrome P450 genes were also more abundant under these primary substrate conditions promoting attenuation of most micropollutants. Full-scale validation studies were performed at a MAR site that had established sequential groundwater recharge systems, that exhibited oxic, oligotrophic conditions. Results are illustrated in Figure 1 revealing a significant increase in performance under these conditions. Findings of this study suggest that very promising opportunities exist to modify design and operation of managed aquifer recharge or engineered biofiltration facilities to select for those microorganisms that can transform even moderately degradable micropollutants more efficiently. #### **Urban Wastewater Management, Combined Sewers, and Antibiotic Resistance Dissemination**

M. Quintela Baluja, Newcastle University / Environmental Engineering; D.W. Graham, Newcastle University / Civil Engineering and Geosciences; J. López Romalde, University of Santiago de Compostela / Department of Microbiology and Parasitology  
Antibiotic resistance (AR) is an evolutionary response in bacteria to antibiotics, which has become a serious worldwide public health concern with antibiotic resistance genes (ARGs) now considered by many as emerging pollutants. Consequently, WHO has appealed for urgent concerted actions by governments, health professionals, industry, and civil society to (i) slow the spread of drug resistance, (ii) mitigate the potential fallout from AR outbreaks, and (iii) preserve

medical advances for future generations. This project evaluated urban sewage management systems and how they affect the dispersion of ARGs to the environment. We specifically monitored a waste treatment plant (WTP) in Northern Spain, which included primary and secondary treatment (conventional activated sludge), and river water above and below the WTP in September 2014. Influent, effluent and intermediate locations in the WTP and also sediment and water column samples were collected and analysed using different culturing media, including: MacConkey agar to quantify total (37 °C) and thermotolerant coliforms (44 °C), and chromogenic agars designed to detect extended-spectrum  $\beta$ -lactamase (chromID ESBL, bioMérieux) and carbapenem (chromID CARBA, (bioMérieux) resistant gram-negative bacteria (total and thermotolerant). Results show that unit operations in the WTP efficiently reduces the total number of bacteria as well as resistant bacteria, especially total coliforms, in final effluents, but showed bacterial increases in the waste sludge. However, thermotolerant bacteria displayed a different pattern, decreasing both through the WTP and also sludge samples. Although the WTP seemed to be reducing ARB in the treatment processes, very high levels of ARB were found downstream WTP. Further examination showed that this was likely because the wastewater inputs to the WTP were in combined sewers, which were overloaded during storms and transiently releasing untreated sewage directly to the river. Our results suggest that part of the solution to reducing ARB and ARG from wastes is modernising the urban wastewater system, specifically reducing combined sewers for sewage carriage. This has particular significance to emerging countries as they build and develop new wastewater collections systems. AR is a global problem that affects developing and developed countries, but other factors such as how the sewage in transported must also be considered in new management systems.

#### **Quantitative analysis of 296 antibiotic resistance and related genes in an urban wastewater treatment plant**

A. Karkman, Department of Food and Environmental Sciences; T.A. Johnson, Michigan State University / Center for Microbial Ecology Department of Civil and Environmental Engineering; K. Pärnänen, C. Lyra, M. Tamminen, University of Helsinki; R.D. Stedtfeld, J.M. Tiedje, Michigan State University / Center for Microbial Ecology Department of Civil and Environmental Engineering; M. Virta, Wastewater treatment plants (WWTPs) receive sewage from various sources, including hospitals and households which are both important sources of antibiotics and their residues, and antibiotic resistant bacteria. Bacteria from various environments are mixed in WWTPs and therefore these facilities are considered to be important hot-spots of antibiotic resistance and spread of resistance genes. In this study we quantified genes related to antibiotic resistance (AR) and horizontal gene transfer (HGT) in inflow, effluent and activated sludge of an urban WWTP over four seasons during one year. The purification process in the plant is based on activated sludge followed by biological post-filtration. In addition the effect of the treated waste water discharge was studied by comparing the sediment near the release pipe with control sediments without direct impact of waste water. The genes were quantified using parallel qPCR array targeting 296 genes (286 ARGs, 9 transposase genes and 16S rRNA gene). Water samples were obtained from Viikinmäki WWTP (Helsinki, Finland) as 24 hour composite samples. Sediment samples were taken from surface sediments. DNA was isolated by using MoBio DNA isolation kits (MoBio Laboratories, Inc., CA, USA). The genes were quantified using highly parallel qPCR array on Applied Biosystems OpenArray platform and normalised with 16S rRNA gene numbers. From the studied 295 AR and HGT related genes 184 were found from the WWTP. The raw inflow water contained the highest number of ARGs, followed by the final effluent and sludge. In the sediments near the release pipe the ARG richness was even lower than in the control sediments. All the different ARG classes and every HGT related gene targeted by the assay were found from the WWTP. The mean ARG richness in the raw inflow was 156 genes (min: 149, max: 165), in the final effluents 70 genes (min: 43, max: 101), in the sludge 55 genes (min: 43, max: 67), in the release site sediment 34 genes (min: 25, max: 42) and in the control sediment 39 genes (min: 24, max: 49). The raw inflow had higher abundance of ARGs compared to both final effluent and sludge ( $p < 0.001$ ). The ARG abundance in the sediments near the release pipe was not significantly different from the control sediments. Our results demonstrate that urban waste water plant is not necessarily a hot spot of the dissemination of antibiotic resistance, even when based solely on biological treatment.

487

#### **Antibiotics and antibiotic resistance genes in hospital and urban wastewaters and their impact on the natural aquatic environment**

S. Rodríguez-Mozaz, Institute for Water Research (ICRA) / Water Quality; S. Chamorro, Catalan Institute for Water Research ICRA; E. Martí, Catalan Institute for Water Research (ICRA); B. Huerta Buitrago, Catalan Institute for Water Research (ICRA) / Department of Water Quality; M. Gros; A. Sanchez-Melsio, Catalan Institute for Water Research ICRA; D. Barcelo, IIQAB-CSIC / Institute for Environmental Assessment and Water Research; C. Borrego, Catalan Institute for Water Research ICRA; J. Balcazar, Catalan Institute for Water Research (ICRA) Antibiotics are widely consumed drugs administered to treat infectious diseases, and large amounts are released into municipal wastewater due to excessive consumption and disposal of unused antibiotics. Overuse and misuse of antibiotics

has led to the emergence of antibiotic-resistant bacteria, compromising the effectiveness of antimicrobial therapy. Aquatic ecosystems are an ideal setting for the acquisition and spread of antibiotic resistance genes (ARGs) due to the continuous release of both antibiotics and antibiotic resistance bacteria into the environment through different routes, such as discharge of wastewater treatment plant (WWTP) effluents. In this work we investigate the pollution level of a broad range of antibiotics ( $\beta$ -lactams, lincosamides, macrolides, quinolones/fluoroquinolones, sulfonamides, tetracyclines, dihydrofolate reductase inhibitors and nitroimidazoles) and ARGs (blaTEM, ermB, qnrS, sulI and tetW), released from hospital and urban wastewaters in Girona (NE Spain), their removal through a wastewater treatment plant (WWTP) and their presence in the receiving river water. Several antibiotics were detected in all water samples collected. Fluoroquinolones were detected at the highest concentration, especially in hospital effluent samples. Although good removal efficiency during WWTP was observed for some antibiotics, most of them were still present in WWTP effluents. Copy numbers of ARGs, such as blaTEM (resistance to  $\beta$ -lactams), qnrS (reduced susceptibility to fluoroquinolones), ermB (resistance to macrolides), sulI (resistance to sulfonamides) and tetW (resistance to tetracyclines), were detected at the highest concentrations in hospital effluent and WWTP influent samples. Although there was a significant reduction in copy numbers of these ARGs in WWTP effluent samples, this reduction was not uniform: Concentrations of ermB and tetW genes decreased during treatment process whereas blaTEM, sulI and qnrS gene copy numbers increased. The incomplete removal of antibiotics and ARGs in WWTP severely affected the receiving river, where both types of emerging pollutants were found at higher concentration in downstream waters than in samples collected upstream from the discharge point. Our findings demonstrate a widespread occurrence of antibiotics and ARGs in urban and hospital wastewater and that inefficient wastewater treatment processes contribute to the spread of these emerging pollutants in the aquatic environment.

488

#### **Exploring plasmid-based dissemination of antibiotic resistance genes in environmental matrices**

C. Merlin, Laboratoire de Chimie Physique et Microbiologie pour l'Environnement; X. Bellanger, H. Guilloteau, CNRS-University of Lorraine / Laboratoire de Chimie Physique et Microbiologie pour l'Environnement

Plasmids are important actors of antibiotic resistance gene dissemination that seriously contribute to reduce the effectiveness of our therapeutic potential. Putting aside the hospital context, considerable efforts are given to identify permissive environments and conditions driving plasmid transfer in microbial communities. Lately, we developed a sensitive molecular approach based on quantitative PCR allowing the detection of the transfer of known plasmids in natural microbial communities maintained in microcosms. Basically, it consists in inoculating microcosms with a donor bacterium and to quantify the relative abundance of both the plasmid and the initial host DNAs over time. Since conjugative transfer is an intercellular mode of DNA replication, the plasmid to donor DNA ratio increases in the community DNA when the plasmid transfers into the indigenous population. This method provides the advantage of considering plasmid transfer in complex communities, culturable or not, and with a sensitivity allowing the detection of rare transfer events under low donor inoculum size. In this work we studied the transfer of the broad host range IncP-1 $\beta$  plasmid pB10 in various environmental matrices, from river sediments, to activated sludge and manure. Under low level of inoculation, the transfer of the conjugative-proficient plasmid pB10 in complex environments appeared relatively rare and was strongly matrix dependent. In some instance the transfer of pB10 in complex communities seemed to be influenced by eukaryotic predation, which alternatively promoted or inhibited plasmid transfer depending on the environmental matrix considered. An attempt to link the microbial community structure to the matrix permissiveness showed that TTGE analysis is not resolute enough to identify key community members supporting pB10 transfer in comparable communities. However, an estimation of the IncP-1 $\alpha/\beta$  plasmids abundance by quantitative PCR demonstrated that pB10 transfer tends to be supported by environmental matrices exhibiting a higher content of IncP-1 $\alpha/\beta$  plasmids. This tend to show that the relative abundance of IncP-1 plasmids in a given microbial community reflects its permissiveness to the transfer of plasmids belonging to the same incompatibility group. Apparently, at community level this phenomenon prevails over transfer limitation due to the superinfection immunity, which combine transfer exclusion and plasmid incompatibility.

#### **Accumulation dynamics and acute toxicity of silver nanoparticles to *Daphnia magna* and *Lumbriculus variegatus*: implications for metal modelling approaches**

K.B. Paul, Heriot-Watt University / SLS; F.R. Khan, Roskilde University / ENSPAC; A. Dybowska, Natural History Museum London / Mineralogy; E. Valsami-Jones, The Natural History Museum; J. R. Lead, University of South Carolina / Center for Environmental NanoScience and Risk; V. Stone, Heriot Watt

University; T.F. Fernandes, Heriot-Watt University / School of Life Sciences Frameworks commonly used in trace metal ecotoxicology (e.g. biotic ligand model (BLM) and tissue residue approach (TRA)) are based on the established link between uptake, accumulation and toxicity, but similar relationships remain unverified for metal-containing NPs. The present study aimed to (i) characterise the bioaccumulation dynamics of PVP-PEG- and citrate-Ag NPs, in comparison to dissolved Ag, in two model invertebrates, *Daphnia magna* and *Lumbriculus variegatus*; and (ii) investigate whether parameters of bioavailability and accumulation predict acute toxicity. In both species, uptake rate constants for Ag NPs were generally 2-10 times less than for dissolved Ag and showed significant rank order concordance with acute toxicity across both species ( $r = -0.857$ ,  $p < 0.001$ , Kendall's tau coefficient). Ag elimination by *L. variegatus* fitted a 1-compartment loss model, whereas elimination in *D. magna* was bi-phasic, comprising fast and slow loss phases. The latter showed consistency with studies that reported daphnids ingesting of NPs, whereas *L. variegatus* biodynamic parameters indicated that uptake and efflux were primarily determined by the bioavailability of dissolved Ag released by the Ag NPs. Our study shows that principles of BLM and TRA frameworks are confounded by the feeding behaviour of *D. magna* where the ingestion of Ag NPs that remain biologically inactive perturbs the relationship between tissue burden and acute toxicity, but such approaches are applicable when accumulation and acute toxicity are linked to ionic concentrations. However, the uptake rate constant, as a parameter of bioavailability that includes all available pathways, could be successful predictor of acute toxicity. **KEYWORDS:** Ag NPs, Biodynamic modeling, nano-BLM, Tissue Residue Approach. **Presentation Preference:** Platform Acknowledgement - The authors thank the Heriot-Watt University NanoSafety group. Funding was provided by the US EPA – UK NERC NanoBEE project.

#### Concentration and form of copper released into aquatic systems from commercial liquid and micronized pressure treated lumber

A.N. Parks, U.S. EPA, Atlantic Ecology Division / Atlantic Ecology Division; M.A. Cashman, US EPA / Atlantic Ecology Division; M.G. Cantwell, Atlantic Ecology Division; D.R. Katz, K.T. Ho, R.M. Burgess, U.S. EPA / Atlantic Ecology Division

The fate and effects of pristine engineered metal nanomaterials (ENMs) in simplified systems have been widely studied; however, little is known about the potential release and impact of metal ENMs from consumer goods, especially lumber which has been treated with micronized copper. Micronized copper treatment solutions contain copper complexes predominately in the 10-700 nm size range, and are used in lumber to prevent microbial degradation and fouling. In this work, the goal was to determine the rate, concentration, and form of copper released from several commercially available pressure-treated lumber samples exposed to an aqueous system at 0, 1, 10, and 30 ppt seawater. Lumber tested included untreated Southern Yellow Pine (SYP) as the control, SYP treated with micronized copper azole (MCA) at 0.96 and 2.4 Kg/m<sup>3</sup>, alkaline copper quaternary (ACQ) at 0.30 and 9.6 Kg/m<sup>3</sup>, and chromated copper arsenate (CCA) at 40 Kg/m<sup>3</sup>. Of the different chemical treatments, only MCA included nano- and micro-sized copper complexes. The experimental system included 2 cm wood cubes cut from the outer surface of the lumber submerged in 250 mL of media (0, 1, 10, and 30 ppt reconstituted seawater) in high density polyethylene bottles, and mixed on a shaker table at 120 rpm for 6 months. Water samples were taken at 8 hours, and on days 1, 2, 7, 14, 28, 133, and 210. Subsamples included unfiltered water, and water filtered through a 0.1 µm polyethersulfone (PES) syringe filter and a 3000 Dalton centrifugal filter, which were analyzed using ICP-AES to determine the total, nano+ionic copper (< 0.1 µm subsample), and presumably ionic-only copper (*Americamysis bahia*) were used to confirm the results of the size-based analyses. Overall these results suggest that the form of copper released from treated lumber is ionic and that little free nanocopper is present. This finding suggests the risk associated with nanocopper treated lumber can be addressed with conventional existing copper ion modeling approaches.

#### Nanosized titanium dioxide mitigates copper toxicity

R.R. Rosenfeldt, University of Koblenz-Landau, Institute for Environmental Sciences / Institute for Environmental Sciences; F. Seitz, Inst. for Environmental Sciences / Institute for Environmental Sciences; J.P. Zubrod, Institute for Environmental Sciences University of Koblenz-Landau / Institute for Environmental Sciences; A. Feckler, Swedish University of Agricultural Sciences (SLU) / Department of Aquatic Sciences and Assessment; S.R. Luederwald, Institute for Environmental Sciences; T. Merkel, University of Koblenz Landau; R. Bundschuh, Institute for Environmental Sciences University of Koblenz-Landau / Institute for Environmental Sciences; R. Schulz, University of Koblenz-Landau / Institute for Environmental Sciences; M. Bundschuh, Department of Aquatic Sciences and Assessment Swedish University of Agricultural Sciences / Department of Aquatic Sciences and Assessment

The increasing use of titanium dioxide nanoparticles (nTiO<sub>2</sub>) as an ingredient in many consumer products (e.g., paints, textiles and sunscreens) inevitably increases the risk of their unintentional release into aquatic environments. Thus, their interaction with other co-occurring stressors (e.g. heavy metals) seems unavoidable. The nanoparticles could adsorb large amounts of metal ions and hence

potentially reduce the concentration of free ions in the water phase, while carrying high loads of them at their surface. The settling nTiO<sub>2</sub> agglomerates – together with the absorbed metal ions – might pose a risk to benthic organisms (e.g. gammarids) in particular. This scenario was assessed by taking advantage of a 2x2 factorial test design, exposing *Gammarus fossarum* to nTiO<sub>2</sub> (0 or 2 mg/L) and copper (Cu; 0 or 40 µg/L) in a 24-d lasting bioassay. The endpoints were mortality, leaf consumption, feces production and assimilation as well as parameters related to physiological fitness. The results showed that nTiO<sub>2</sub> caused no mortality and no reduced leaf consumption, while Cu led to a high mortality of *G. fossarum* (71%). In addition, Cu caused a 25% reduction in leaf consumption as well as a 30% reduction in feces production compared to the control, respectively. The presence of nTiO<sub>2</sub> mitigated the toxic effects of Cu observed in the absence of nTiO<sub>2</sub>. For instance, the mortality was more than 4-fold reduced and the leaf consumption reached levels comparable to the control. However, gammarids exposed towards nTiO<sub>2</sub> displayed a reduced assimilation and a lower weight compared to the control. Therefore, potential long term effects of nTiO<sub>2</sub> should be thoroughly investigated, before considering the application of nTiO<sub>2</sub> as a remediation agent for e.g. waste water or highly contaminated surface waters.

#### Designing safer nanomaterials towards a sustainable nanotechnology: a case study with hydrophobically modified polyacrylic acid nanomaterials

J.A. Tavares, University of Aveiro, Department of Biology & CESAM / Biology; C. Venâncio, Biology; C. Duarte, F. Antunes, University of Coimbra; A.M. Soares, Universidade de Aveiro / Department of Biology and CESAM; I. Lopes, University of Aveiro / CESAM Biology Department

The growing demand for new and better products led to an exponential development of manufactured nanomaterials (MNM) since the 90's decade. The current widespread use of MNM in consumer products is promoting the contact between nanomaterials and the environment, which may lead to adverse effects in the latter. The present work aimed at suggesting the most environmental-friendly hydrophobically modified polyacrylic acid (HMPAA) MNM in order to contribute for the European Union agenda on Nanosafety: safe and sustainable nanomaterials and nanotechnology innovations<sup>2</sup>. Six variations of HMPAA MNMs were obtained by modifying the crosslinked conformation, the insertion position and the length of hydrophobic groups. Each variation of HMPAA suspensions were characterised by using light scattering techniques. Conductivity and pH were also measured. To characterise the ecotoxicity of the six MNMs a battery of lethal and sublethal standardised assays were conducted with species from different taxonomic and functional levels to assess different ranges of sensitivity: (i) *Vibrio fischeri* (Azur, 1998), (ii) *Raphidocelis subcapitata* and *Chlorella vulgaris* (OECD, 2006)<sup>3</sup>, (iii) *Brachyonus calyciflorus* (Microbiotest, 1998), (iv) *Daphnia magna* (OECD, 2008), and (v) *Pelophylax perezi*, (ASTM, 2007). The concentrations causing 50% and 20% of effects (LC50 for mortality and EC50/EC20 for sublethal endpoints) were computed for each monitored endpoint. Computed LC and EC values ranged from 9.64 mgL<sup>-1</sup> up to 2000 mgL<sup>-1</sup> for all tested MNMs and species. In general, the most sensitive species to the tested MNMs was the bacteria *Vibrio fischeri*, while *Pelophylax perezi*, showed to be most tolerant. The HMPAA1 and HMPAA2 proved to be amongst the most toxic tested MNMs. In contrast, HMPAA5 and HMPAA6 where, in general, the least toxic to freshwater biota. For the two tested algae species, HMPAA5 was the less harmful MNM, and HMPAA 6 was the less toxic MNM to *Vibrio. fischeri*, *Brachyounus calyciflorus* and *Raphidocelis subcapitata*. It is suggest that industries should develop HMPAA with hydrophobic groups (short and long) at the surface of the MNM as it seems to reduce their adverse effects to biota while maintaining its functionalization, thus contributing to a more sustainable development and greener nanotechnology.

#### Demonstrating approaches to chemically modify the surface of Ag nanoparticles in order to influence their toxicity and biodistribution

C. Pang, University CaFoscari Venice / Dept of Environmental Sciences Informatics and Statistics; A. Brunelli, Environmental Sciences Informatics and Statistics; W. Tao, Research Center for EcoEnvironmental Sciences Chinese Academy of Sciences / State Key Laboratory of Environmental Chemistry and Ecotoxicology; D. Hristozov, Ca Foscari University of Venice; E. Semenzin, Ca Foscari University of Venice / Department of Environmental Sciences Informatics and Statistics; A. Marcomini, University of Venice / Department of Environmental Sciences Informatics and Statistics; C. Chen, National Center for Nanoscience and Technology of China / CAS Key Laboratory for Biomedical Effects of Nanomaterials Nanosafety; B. Zhao, RCEES, CAS

With the advance in material science and the need to diversify market applications, silver nanoparticles (AgNPs) are modified by different surface coatings. However, how these surface modifications influence the effects of AgNPs on human health is still largely unknown. We have evaluated the uptake, toxicity, and pharmacokinetics of AgNPs coated with citrate, polyethylene glycol, polyvinylpyrrolidone and branched polyethyleneimine (Citrate AgNPs, PEG AgNPs, PVP AgNPs and BPEI AgNPs, respectively). Our results demonstrated that the toxicity of AgNPs depends on the intracellular localization that was highly dependent on the surface charge. BPEI AgNPs ( $\zeta$  potential = +46.5 mV) induced the highest cytotoxicity (EC<sub>50</sub>=10.38 µg/ml) and DNA fragmentation in Hep1c1c7. In addition, it showed the highest damage to the nucleus of liver cells in

the exposed mice, which is associated with the highest cellular uptake and high accumulation in liver tissues. The near neutral PEG AgNPs ( $\zeta$  potential = -16.2 mV) showed the lowest toxicity ( $EC_{50}$  = 63.14  $\mu$ g/ml), a long blood circulation ( $t^{1/2\alpha}$  = 1.04 h,  $t^{1/2\beta}$  = 436.67 h), as well as a high bioaccumulation in spleen (34.33  $\mu$ g/g), which suggest better biocompatibility compared to the other chemically modified AgNP. Moreover, the adsorption ability with bovine serum albumin revealed that the PEG surface of AgNPs has an optimal biological inertia and can effectively resist opsonization or non-specific binding to protein in mice. The overall results indicated that the toxicity of AgNPs was significantly dependent on surface chemistry: BPEI AgNPs > Citrate AgNPs = PVP AgNPs > PEG AgNPs. This kind of toxicological data could be useful in supporting the development of safe by design AgNPs for consumer products and drug delivery applications.

## Challenges of regional and global modelling nitrogen and phosphorus in agriculture supply chains

494

### The importance and challenge for accounting of soil stock changes in N footprint and N budget studies

A. Leip, Institute for Environment and Sustainability; F. Özbek, European Commission Joint Research Centre / Institute for Environment and Sustainability; O. Hutton, University of Virginia / Department of Environmental Sciences Engineering; A. Leach, J. Galloway, University of Virginia / Department of Environmental Sciences  
Nitrogen Use Efficiency (NUE) and the Nitrogen Balance (NB) are key indicators assessing the sustainability of agricultural production. When determining NUE or NB for regions or countries on the basis of standard methodologies, accumulation of nitrogen in soils or depletion of nitrogen from soil resources is usually left out of the equation. Yet, soil stock changes might be important elements for the NUE or NB for a crop, with accumulations of N in the soil increasing the NUE and reducing the NB and the inverse effect when soil is losing N from its organic matter (1, 2). For Tanzania, Hutton et al. (3) propose the estimation of the “Soil Mining Factor” (SMF), based on the observation that the majority of fields (91%) in Tanzania were unfertilized and produced only half as much grain than on fertilized fields. This was used to calculate that 83% of N in harvested grains in Tanzania originates from soil reserves. SMF as kg of N lost per kg of N consumed in households for vegetable products in Tanzania range between 1.1 and for wheat and 1.9 for vegetables. For Turkey, Özbek and Leip (4) propose a methodology based on the observation that for many countries the NB method yields very low (or even negative) N surplus, with unrealistically high NUE values. Using detailed NB data for 26 administrative regions in Turkey they developed a hyperbolic regression model estimating a relationship between N uptake and N input for those regions with NUE below a threshold of 85% and using this relationship to re-estimate NUE and NB for all regions in Turkey. The model estimated an average N surplus of 33 kg N ha<sup>-1</sup> yr<sup>-1</sup> (average 2007-2011) and a NUE of 65%. Losses of nitrogen is not restricted to soils with a negative balance. Efforts are needed to provide estimates for nitrogen soil stock changes in national or regional nitrogen balance calculations despite high uncertainties – unavoidable in view of the lack of good and sufficient data. The methods presented here provide pragmatic solutions to do so in two very different settings. Application of the methods to other countries and regions might provide important insight into nitrogen dynamics in agricultural soils. 1. A. Leip et al, *Environ. Pollut.* **159**, 3243–53 (2011). 2. Eurostat and OECD, *Nutrient Budgets, Methodology and Handbook. Version 1.02*, Luxembourg, 2013. 3. O. Hutton et al., *Environ. Res. Lett.* **submitted** 4. F. ### Using a process-based simulation model for nitrogen emissions in life cycle inventory analysis of crop production

W. Liao, INRA / Environnement et Agronomie; H.M. van der Werf, INRA, UMR SAS / Environnement et Agronomie; J. Salmon-Monviola, INRA  
The input-emission nonlinearity resulting from complex biogeochemical processes in crop production has posed a challenge to the life cycle inventory analysis (LCI) of reactive nitrogen (N<sub>r</sub>) emissions. The local soil-climatic conditions and agricultural practices affecting these processes, and the spatial scale of production are subject to improved modelling. This study aims at presenting an LCI model coupled with a process-based simulation model for an improved estimation of N<sub>r</sub> emissions in the LCI of crop production. The model coupled with LCI is the spatially explicit agro-hydrological model TNT2. In TNT2-LCI on-site and off-site N<sub>r</sub> emissions were distinguished and daily fluxes of on-site NO<sub>3</sub><sup>-</sup> and N<sub>2</sub>O due to denitrification of leached NO<sub>3</sub><sup>-</sup> (N<sub>2</sub>O<sub>leach</sub>) were integrated over an inventory period to provide unit process data. The current LCI model compared with TNT2-LCI is AGRIBALYSE which set standard inventory periods and estimated on-site NO<sub>3</sub><sup>-</sup> based on a field-scale model. Three cropping systems including permanent meadow (S1), continuous silage maize (S2), and a sequence of different annual crops (S3) were configured in the catchment Kervidy-Naizin in Brittany, France, for a multi-year case study. An annual pattern of “waves” appeared in the time series of on-site NO<sub>3</sub><sup>-</sup>/N<sub>2</sub>O<sub>leach</sub> emissions in TNT2-LCI. Specific time intervals for these waves were identified as the basis to define more appropriate inventory periods than those set in AGRIBALYSE. When AGRIBALYSE was used, a single value for

on-site N<sub>r</sub> was provided for a given crop, and different crops had different values. When TNT2-LCI was used, NO<sub>3</sub><sup>-</sup>/N<sub>2</sub>O<sub>leach</sub> emissions changed from one year to another for S1 and S2, and larger variation of NO<sub>3</sub><sup>-</sup>/N<sub>2</sub>O<sub>leach</sub> emissions between different crops was observed for S3. Applying TNT2-LCI to the three systems resulted in higher average values of NO<sub>3</sub><sup>-</sup> than obtained when using AGRIBALYSE. Both models agreed that S1 had the lowest on-site NO<sub>3</sub><sup>-</sup>/N<sub>2</sub>O<sub>leach</sub> emissions and S2 the highest. We presented the model TNT2-LCI. The primary benefit added by TNT2-LCI to current LCI practice lies in its ability to better consider soil-climatic conditions, N<sub>r</sub> dynamics, and agricultural practices. In the case study of crop production, TNT2-LCI and AGRIBALYSE have shown to give different results on on-site N<sub>r</sub> emissions. Furthermore TNT2-LCI allows the definition of more appropriate inventory periods for an improved estimation of the unit process data on on-site N<sub>r</sub> emissions.

### Comparison of process-based models to quantify major nutrient flows and greenhouse gas emissions associated with milk production

O. Jolliet, University of Michigan / Environmental Health Sciences School of Public Health; K. Veltman, University of Michigan / Department of Environmental Health Sciences

Assessing and improving the sustainability of dairy production systems requires an accurate quantification of major nutrient (N,P) flows and greenhouse gas (GHG) emissions associated with milk production at the animal, farm and field-scale. In large, nonhomogeneous countries like the US, milk production practices and climate conditions vary widely, which can result in large, farm-specific variations in GHG and nutrient emissions. Life cycle inventory databases are, however, often based on rough estimates of GHG emissions and nutrient flows, and cannot account for spatially-explicit variation in these flows. Emission estimates can be improved when underlying processes influencing GHG emissions and nutrient balances are explicitly considered. We aim to improve life cycle inventory databases for milk production by integrating process-based models into LCA data acquisition. We therefore perform a quantitative comparison of five process-based models to determine major nutrient flows and GHG emissions of milk production at the animal, farm and field-scale. We use a whole-farm, mass-balance approach to compare model predictions of nutrient (N,P) flows to empirical data. The whole-farm approach reveals trade-offs between emissions of the different GHGs and other pollutants, and ensures that interactions between nutrient cycles are taken into account. In addition, this approach allows comparison of model predictions with empirical nutrient flows in absence of measured emission data and can be used to check for an internal consistency in model predictions. Taking the manureDND model as an example, the first mass-balance results show that this model correctly predicts the N flow in milk&meat and in feed crops. Current research focusses on developing a whole-farm P mass-balance. Our results furthermore show that CH<sub>4</sub> emissions are dominating the total global warming impact at the individual farm level. Enteric CH<sub>4</sub> emissions contribute substantially to the total GWP, although manureDND predicts a dominant contribution of lagoon CH<sub>4</sub> emissions. Differences in predicted NH<sub>3</sub> emissions are within a factor 10 and corn is the dominant contributor to N<sub>2</sub>O emissions from field. Once models are evaluated and harmonized, integrating process-based models into LCA data acquisition, as proposed here, can provide a more accurate, spatially-explicit approach to derive farm-specific nutrient flows and GHG emissions, which is essential to improve sustainability assessments of dairy production systems.

### Regionalised aquatic eutrophication impacts from phosphorous emissions in crop production

L. Scherer, S. Pfister, ETH Zurich

Aquatic eutrophication describes the degradation of freshwater quality due to excessive amounts of nutrients, primarily phosphorus, which adversely affect ecosystem health. The phosphorus emissions might originate from fertilizer application, but also arise from the mobilisation of soil phosphorus during erosion. Data on such emissions are scarce and mostly confined to global and a few national estimates, even in widely used databases such as ecoinvent. Previous regionalised assessments involved simplified model inputs such as globally constant phosphorus concentration in soil and predefined tabulated values for soil erodibility and were mostly limited to a few crops. In this study, the emissions were simulated for the global production of 169 crops at a resolution of 5 arc-minutes (about 10 km). Two models were combined and their input data improved. The Universal Soil Loss Equation (USLE) was used to estimate soil erosion and was coupled with the Swiss Agricultural Life Cycle Analysis (SALCA) model to calculate the emissions from four different processes: erosion, runoff, drainage and groundwater leaching. The resulting emissions were considered as life cycle inventory and translated into impacts on species richness via spatially explicit characterisation factors. Furthermore, the contribution of regionalised phosphorus emissions to the spatial variability of the environmental impacts was compared to that of the characterisation factors (contribution to variance analysis). It was shown that globally erosion and the mobilisation of soil phosphorus are the dominant cause for phosphorus emissions to freshwater, although groundwater leaching and fertilizer application play a prominent role in the temperate climate zone. Our results indicate that the phosphorus emissions in the ecoinvent database are greatly underestimated for the global average of the main crops. Furthermore, the contribution to variance

analysis highlighted the importance of regionalising both emissions and characterisation factors. Therefore, we strongly recommend using the crop-specific, regionalised results of this study.

#### **Substance Flow Analysis on Agricultural Nutrients focusing Nitrogen and Phosphorus**

T. Yamamoto, K. Matsubae, Tohoku University; K. Nakajima, National Institute of Environment Studies; K. Nansai, Nat. Inst. of Env. Studies (NIES); T. Nagasaka, Tohoku University

Agricultural nutrient such as phosphorus, potassium and nitrogen are essential elements for food production. These elements are called three major elements of fertilizer and the demand of them has been increasing not only for agricultural industry but also for other industries. In 2050, the world population will reach more than 9 billion and stable food supply is one of the most important issues.

Furthermore, amount of bioethanol production has increased about three times in the past ten years. From these reasons, the demand of the three elements will increase as well as that of fertilizer. The aims of this study were the following three, (1) to grasp supply and demand of nitrogen and phosphorus using material flow analysis; (2) to estimate global phosphorus and nitrogen flows associated with export and import of various commodities; and (3) to analyze phosphorus and nitrogen consumption between the Japanese domestic economy and the global supply chain using the GLIO model. Furthermore, we have quantitatively clarified agricultural nutrients consumption for various countries and discussed the possibilities and bottlenecks of recovery and recycling of N and P from the waste streams. The method of this study was threefold, (1) Material flow analysis of nitrogen and phosphorus subject to 2005 in Japan. (2) The estimation of nitrogen and phosphorus accompanied with each item traded among 231 countries and regions basis of BACI. 423 types of N and 281 types for P contained products were chosen from HS code. (3) The agricultural nutrient flows into the 2005 input-output model of the Japanese economy, and integrates international trade statistics on the basis of Global Linkage Input Output (GLIO) model. The result of this study about nitrogen, North America and China are the key stakeholders, which have large amount of excess balance of nitrogen. About phosphorus, North and South America and China have large amount of excess balance of phosphorus, while most African countries, even P ore mining countries, face on the low balance of P. From the estimated results, nitrogen and phosphorus are flow in as fertilizer and feed, and mostly ended up to flow out the environment in the developed countries. It is expected that the consumption of nitrogen and phosphorus will increase as the economic development in BRICS and VISTA. The more effective utilization of these nutrients and the geopolitical and environmental governances are strongly required in coming decades.

##### **How much biochar does gasification bioenergy need to be carbon neutral?**

K. Saez de Bikuña, Chemical Biochemical Engineering; A. Ibrom, DTU Technical University of Denmark / Chemical and Biochemical Engineering; M. Hauschild, DTU Management Engineering

Indirect land use changes (iLUC) from bioenergy emerge whenever an energy crop is planted in arable land [1]. Due to their overarching magnitude from a life-cycle perspective, they have been repeatedly recommended to be included in bioenergy's greenhouse gas (GHG) accountings, despite their challenging quantification and inherent uncertainties [2], [3]. Marginal or abandoned lands have been often quoted as the solution to avoid these undesired effects from bioenergy [4], [5]. However, land abandonment and marginalization is to a large extent a socio-economic process, and thus heavily depends on specific, constantly changing socio-political context and economic circumstances in place [6]–[8]. We suggest a carbon negative bioenergy system that compensates for potential iLUC emissions and losses in soil organic carbon (SOC). A consequential life cycle assessment on willow bioenergy has been performed, distinguishing marginal and arable land scenarios. Specific soil types and their estimated SOC changes have been considered [9], as well as iLUC emissions for the arable case [10]. Taking the study case of a willow plantation combined with a medium-scale gasification plant in Denmark, we illustrate the biochar needed from the process in order to remain carbon neutral. The time scopes assessed are 20 and 100 years and it is assumed a fossil fuel (FF) free Denmark beyond 2050 as targeted by government (no FF displacement occurs after 2050). Results show that willow on marginal land remains carbon negative (4% biochar fraction) for the short term, while as much as 31,8% of biochar (or 0,95 Mg C ha<sup>-1</sup> yr<sup>-1</sup>) would be necessary in 100 years to be carbon neutral (taking natural vegetation as reference baseline). As for arable land willow, a biochar fraction of 34,1% (or 2,32 Mg C ha<sup>-1</sup> yr<sup>-1</sup>) would be necessary in the short term to compensate for iLUC emissions, while a 4% would suffice to make it carbon negative in the long term, as iLUC “dilutes” over 100 years. To achieve such high biochar fractions (>10%), lower process temperatures are needed, which affect negatively the long-term stability of biochar [11], [12]. This can put at risk the claimed GWP

reduction benefits. This study did not consider impacts on other environmental aspects as ecosystem services and biodiversity, which are deemed to be rather important and significant for iLUC.

500

#### **LCA of alumina nanofluid used as coolant in Power Electronic Traction system**

S. Scalbi, P. Masoni, ENEA / LCA and Ecodesign Laboratory

Nowadays the emerging nanomaterials are spreading in several markets, so the potential environmental impacts evaluation is essential to avoid undesirable effects on environment. The study aim is to analyse from cradle to grave the environmental impact of the alumina nanofluid (NF) used as coolant in the cold plate of the Insulated Gate Bipolar Transistor (IGBT). This is a modern device used in Power Electronic Traction system (PET). The main problem in PET is the effective temperature management because the efficiency depends on the cooling system. A comparative LCA was developed to study the environmental impacts of three systems: 1. Baseline Cooling System (BCS) using water and glycol as refrigerant; 2. Nanofluid Cooling System single stage (NCS single) using alumina NF refrigerant produced with the single-stage process (wet chemical synthesis to form and disperse tailored nanoparticles within a fluid); 3. Nanofluid Cooling System two stage (NCS two) using alumina NF produced with the two-stage process (batch process added pre-produced nanoparticles to a fluid). The system function is removing heat from PET in order to improve its performances and lifetime in trains. The functional unit is a liquid cooling system for PET, capable to keep specified performance and with a lifetime of 30 y. The different lifetime among the BCS (30y) and the other NCS (37y) systems has been considered. Both NCS show lower potential environmental impacts than the BCS for all impact categories. The differences are very little, probably due to the short time lapse considered (30 y). In particular “NCS two-stage” has lowest potential impacts for all categories this is due to the less energy consumption in the alumina NF two stage production. Therefore a sensitivity analysis using several lifetime shows that, increasing the lifetime of NCS until 41y, there are more potential environmental advantages for all impact categories due to reduction in use of materials. The results show that abiotic depletion is a relevant impact that could be reduced substituting and/or reducing some scarce raw materials. Energy saving is another important issue, that deserves further developments. The end of life of nanofluid has little impact (less than 3% for all impact categories), due to the great impact of metals and energy production. Nanomaterials toxicity is not included because, to date, their characterization factors for toxic categories are lacking.

501

#### **Meeting international transport electrification goals: the impacts on metallic resource use and competition**

V. De Bruille, CIRAI - École Polytechnique de Montréal / Chemical Engineering; C. Bulle, CIRAI - ESG - UQAM / Strategy corporate social responsibility; C. Gaudreault, NCASI Canada; T. Dandres, CIRAI; R. Samson, École Polytechnique de Montréal / Department of Chemical Engineering

Transport electrification is one of the biggest technological transitions of our time and this study analyzes implications, from a metallic resources availability perspective, of international policymaking goals for worldwide introduction of electric vehicles (EVs) by 2020 and 2030. To meet 2020 and 2030 policies, an introduction and maintain of an EV fleet of 3 800 000 or 15 million vehicles is required. On one hand, the amounts of resources needed were assessed and compared to overall global availability and primary production as on the other hand, the sensitivity of the MACSI, a competition factor used as LCIA midpoint indicator for the evaluation of resource depletion, to a major technological shift was tested. A general explanation on how MACSI is calculated to assess resource depletion is also shown. Resources for which average annual production needs to be increased significantly (>1%) are lithium and cobalt when EVs are li-ion battery powered and nickel, rare earths and lithium when EVs are NiMH battery powered. Although production needs to be increased for these resources, the competition factor is quite stable in terms of resource ranking when introducing such a key technological shift. Along the electrification scenario of meeting and maintaining the 2020 and 2030 goals, a total worldwide replacement of the light-duty fleet (i.e. 750 million vehicles) scenario was imagined. When considering this global transition to EVs, cobalt, copper and lithium show a very significant increase in competition factors (variations of 87%, 58% and 71%, respectively) and an important reduction in the number of years before reserve base depletion (variations of 81%, 13% and 94%, respectively). Therefore, although competition modeling is a robust indicator when looking at a short term transition, there is a need to update its values and its ranking when a long-term perspective is considered.

502

#### **Using the reliability theory for interpreting comparative LCA**

w. wei, Irstea Clermont Ferrand; P. Larrey-Lassalle, IRSTEA Montpellier; T. Faure, LISC IRSTEA; N. Dumoulin, Irstea - Lisc; P.C. Roux, Irstea / UMR ITAP ELSA; J. Mathias, Irstea - Lisc

The interpretation of results is one of the four main phases of LCA according to the ISO standards. It identifies, quantifies, and evaluates information from the results of the Life Cycle Inventory (LCI) and the Life Cycle Impact Assessment (LCIA) in order to provide recommendations that allow decision makers to take future

decisions. However, today LCA still needs robust interpretation methods for addressing results uncertainty. Here we apply a approach called reliability analysis for comparative LCA interpretation. Reliability analysis aims at comparing two products and calculates the failure probability which expresses the probability of a product to have a smaller environmental footprint than that of another product. The failure probability also represents the probability that the decision maker takes a wrong decision. Many reliability methods are available. Here we compare two methods: Monte Carlo simulations and the FORM method. Monte Carlo simulations give us the failure probability (in terms of decision). The FORM method enable us to approximate the failure probability with fewer simulations than Monte Carlo simulations. Moreover, the FORM method calculates the associated important factors (according to the failure probability) which identify a sensitivity analysis in relation to the decision. The important factors provide the sensitivity coefficient to decision makers in order to determine which factors influence their decision. Our results clearly show that the reliability method provides a further useful means of information for the LCA practitioners and decision makers.

503

#### **Assessing and communicating uncertainties in life-cycle based assessments: lessons learned and ways forward**

J. Clavreul, Unilever R&D Colworth / SEAC

The assessment of uncertainties and variability in life cycle assessment (LCA) is recognised as a need for making results more robust and strengthening LCA as a key decision making tool. Historically, there are few examples of employing techniques for assessing uncertainty and variability in LCA; however, some practices have become much more common in recent years, thanks mainly to the introduction of the ISO 14044 standard. The techniques used are usually limited to sensitivity analyses which consider one factor at a time but there are high quality examples of the application of more advanced methods in the literature. These techniques include for example the separate reporting of uncertainty and variability, the use of input-output techniques or the use of variance-based sensitivity analysis techniques. They often provide new and valuable insights but their applicability to day-to-day assessments often appears challenging. The author discusses some of the challenges and opportunities involved in assessing and communicating uncertainties for decision support in an industrial context. A review is presented that explores how this can be done in practice for the different types of business decisions encountered in a fast moving consumer goods industry. Using past experience of uncertainty assessment and communication, general guidance is derived on how to represent data quality at various stages of the value chain, aid the interpretation of LCA results and thus enhance evidence based decision making. Based on this experience, a discussion is presented about the major challenge that lays in the communication of uncertainty analysis results in an appropriate form to often non-expert decision makers and stakeholders. Depending on the level of details needed, different approaches can be adopted ranging from incorporating the underlying uncertainty within the assessment result to the communication of complex results via linguistic or graphical mechanisms. Finally ways forward to help strengthen the field of uncertainty and its communication in industry applications are suggested.

### **Risk assessment, risk management and mitigation for pesticides: from regulation to public perception (II)**

504

#### **Effects characterization for aquatic invertebrates exposed to imidacloprid-Part A: A novel evaluation rubric to assess aquatic toxicity studies**

L. Knopper; R.L. Breton, Intrinsik Environmental Sciences, Inc.; D. Moore, Intrinsik Environmental, Inc.; T. Hall, Bayer CropScience / Environmental Toxicology and Risk Assessment; L.M. Bowers, Bayer CropScience / Environmental Safety

A review of the scientific literature, registrant-sponsored studies, government agency databases, existing water quality guideline documents and the grey literature revealed 140 studies of the toxicity of imidacloprid to aquatic invertebrates. Tier I acute and chronic laboratory studies were in the majority (n=110); the remainder (n=30) were higher tier studies (microcosm, mesocosm, rice paddy). Before being used in ecological risk assessment, studies need to be critically evaluated for relevance and quality. We developed an evaluation strategy based on a number of questions (specific to study type and chemical), scored from 0 to 3, to address four assessment factors: utility, objectivity, clarity and transparency, and integrity. A detailed evaluation rubric accompanied the evaluation strategy, which provided transparent and clear expectations for each score. With this strategy, a study could score between 0 and 26 (Tier I studies based on 15 questions) or 0 and 29 (Tier II studies based on 16 questions). Studies were rated acceptable, supplemental or unacceptable. Studies were split into two groups and reviewed independently by two reviewers. A subset (~30%) of each group was re-evaluated by the opposite reviewer as part of a Quality Assurance/Quality Control process. The first step in the evaluation process was to evaluate data against utility (i.e., relevancy) questions. Only studies deemed relevant for risk assessment were further evaluated against the other assessment factors. Of the 110 laboratory studies, 84 were rated as relevant and evaluated for data quality: 25 were rated as

acceptable, 27 were rated as supplemental and 22 were rated as unacceptable. Of the 30 higher tier studies, 19 were rated as relevant and evaluated for data quality: 10 were rated as acceptable, eight were rated as supplemental and one study had both acceptable and supplemental data. No higher tier studies were unacceptable. Typically evaluators came to the same numeric score or differed by one or two points, highlighting the transparent, consistent and repeatable nature of this novel evaluation scheme. Details of the evaluation process, specific questions and the scoring rubric will be presented. The strength of the acceptable studies and key data missing for studies that were supplemental and unacceptable will be discussed. The quantitative and qualitative use of supplemental studies as part of the evidence-based risk assessment process will be presented.

505

#### **Aquatic Risk Assessment for Imidacloprid Using All Available Evidence**

A. Weyers, Bayer CropScience / Environmental Safety Ecotoxicology; E. Klamroth, Bayer CropScience / Global Regulatory Management; E. Bruns, Bayer CropScience AG / BCS D ETX Ecotoxicology; C. Garside, Bayer CropScience / Environmental Safety Assessment

For a comprehensive risk assessment for Imidacloprid and aquatic organisms, Bayer Crop Science has generated studies under both laboratory and under more realistic outdoor conditions resulting in a large data base of information. In a recent publication further data were generated under laboratory conditions showing chronic effects for certain species that are lower than were reported before. However, for regulatory purposes these have shortcomings, reported only very briefly, and are partly inconsistent. When evaluating all available data in context, the BCS mesocosm, and also other meso-/microcosm studies (including available literature studies) show that under realistic semi-field conditions concentrations in the µg/L range are needed to produce population relevant effects even on the most sensitive organisms (aquatic insects, especially Chironomids and mayfly). Higher ecologically acceptable concentrations may apply in other regulatory systems worldwide, if small or shortterm effects are accepted, or when protection goals differ between agricultural areas and more remote, natural areas. In accordance with the evaluation scheme in the EU lower tier (e.g. SSD based on laboratory data) should not overwrite higher tier (micro- or mesocosm) toxicity results. The tiered approach is state of the art in pesticide evaluations and should be followed. An evaluation of all data available so far shows that the current RACs for imidacloprid are protective, based on a mesocosm NOEC of 0.6 µg/L.

506

#### **Linking protection goals and exposure in the field for realistic earthworm risk assessments**

A.S. Johnston, University of Reading / Biological Sciences; P. Sweeney, Syngenta; R. Sibly, University of Reading; P. Thorbek, Syngenta / Environmental Safety Pesticide risks to populations are typically investigated under standardised laboratory conditions. However, field populations are rarely exposed to pesticides at a single dose under constant environmental conditions. Field conditions are highly variable and the exposure earthworms experience depends on e.g. climate, soil type, environmental fate and tillage. To address this we used mechanistic models of earthworms (the dominant arable earthworm the endogeic *Aporrectodea caliginosa* and the anecic *Lumbricus terrestris*, an important species in conservation agriculture). We used a previously published and validated model of *A. caliginosa* (Johnston et al. [1]) and developed a new model of *L. terrestris* to simulate earthworm population dynamics in response to pesticides with different environmental fates. We use FOCUS to simulate realistic exposure of earthworms to mobile, medium and immobile pesticides, and compare these scenarios to predicted uniform environmental concentration (PEC) as calculated in standard risk assessments. The pesticide application scenarios are hypothetical and simulated at the same rate, with 20 % nominal effects on life cycle processes (survival, growth and reproduction). The models account for environmental and pesticide effects by combining energy budget and individual-based approaches. Movement of worms responds to a trade-off between soil water and food quality conditions. Population dynamics then emerge from simulation of individual interactions in heterogeneous soil profiles, which vary in their environmental and management conditions. The environmental fate of pesticides and worm movement govern the exposure of earth worms to potentially harmful concentrations and so too the protectiveness of the risk assessment. For both species the PEC scenarios were over-protective compared to the FOCUS scenarios. In the FOCUS scenarios, the interaction between individual behaviour (movement) and pesticide exposure drives the population response. Our results illustrate how important capturing realistic species behaviour and pesticide environmental fates are in conducting realistic risk assessments, whilst current risk assessment approaches can be overly protective. We hope that our mechanistic modelling approach can help improve the way lower tier earthworm risk assessment is carried out.

#### **Use of lab and field studies to develop a comprehensive risk assessment of methoxyfenozide for honey bees**

G. Meregalli, Dow AgroSciences Italia srl / Regulatory Scies & Government Aff.; V.J. Kramer, Dow AgroSciences LLC / Analytical Chemistry and Environmental Sciences

Methoxyfenozide is an ecdysone receptor agonist that behaves very differently

from other insect growth regulators such as chitin synthesis inhibitors and juvenile hormone analogues. Several lab and field studies, including hive feeding studies, have shown low to no effects of methoxyfenozide on honey bee adults and brood. Field exposure studies were conducted to determine potential residues found in hives following applications in blooming orchards. Residues in pollen, nectar and honey bee larvae were quantified. An exposure-based risk assessment comparing exposure to toxicity showed low risk to honey bee colonies following field applications of methoxyfenozide.

## 508

### A comparative distribution-based analysis of HC5 values and data from ecological communities results in similar ecotoxicological thresholds of concern for PSII inhibiting herbicides

M. Gustavsson, Department of Biological and Environmental Sciences; L. Posthuma, D. De Zwart, RIVM / Centre for Sustainability Environment and Health; T. Backhaus, University of Gothenburg / Department of Biological and Environmental Sciences

Species sensitivity distributions (SSDs) and distributions of toxicity values are used for determining toxicological and ecotoxicological thresholds, the HC5 (hazardous concentration for 5% of the species) and the TTC (threshold of toxicological concern), respectively. An SSD describes the sensitivity distribution of a range of species towards a single toxicant, while the TTC is based on the toxicity distribution of a range of different compounds towards the same species or group of species. Both concepts can be combined by using the distribution of HC5 values for a group of substances in order to estimate the TTC. HC5- as well as TTC-values are usually based on toxicity data from standard single species assays. However, the ecological impact of a compound is the result of the reaction of a range of interacting species. In order to explore the impact of using data from ecological communities instead of single species, we performed a comparison of the TTC based on HC5-values with the TTC based on community ecotoxicological data (threshold of concern for community toxicity, TCCT). This study was performed by using toxicity data for Photosystem II- inhibiting herbicides to single algal species and algal communities. Single-species based SSDs and the corresponding HC5 values were established for seven different herbicides. Community ecotoxicity data were collected for 17 herbicides. The resulting thresholds were 6.8 nmol/L for the TTC based on HC5 values and 3.5 nmol/L for the TTC based on community data. This indicates that indirect ecological effects and species interactions do not seem to play a major role, as long as photosynthesis is in focus.

## 509

### A new method for assessing environmental risk of plant protection products

M. Klar, H. Sundberg, J. Axelman, Swedish Chemicals Agency  
An analysis of the validity of the current risk assessment methodology from regulatory point of view, indicates that it is not sufficiently valid nor reliable, which are fundamental criteria of a scientific method. It is concluded that current methodology is highly complex, flexible, non-standardised and relies to a great extent on expert judgement, which makes conclusions unpredictable, and has practical implications on the member states ability to fulfil legally binding authorisation time-limits. The unavoidable component of subjectivity that lies within expert judgement hampers the method's appropriateness from a harmonisation perspective. Further, it is concluded that the overall uncertainty in environmental risk assessment is high. In summary, current methodology is inappropriate as a decision base within the regulatory context. In conditions of low validity and high uncertainty, it is suggested to restrict the method to fewer predictors of equal weight. This would increase the predictive ability in a broader context as bias towards the sample is reduced; it would increase transparency; and decrease the need of validating data. To increase reliability further, we propose to standardise input data and minimise the influence of expert judgement on individual products by limiting the assessment using only first-tier. This would improve output/conclusion predictability of assessments as well as facilitating the dossier compilation, which in turn would reduce business risks and authorisation costs. Exposures and effects from pesticides in the field should be compared with the outcome of the risk assessment, i.e. prospective and retrospective risk assessments should be applied in concert. Since also the proposed method's validity will be low, a continuous feed-back loop of validating effect and exposure data is crucial to refine and improve the method. To sum up, as a remedy to the shortcomings of the current methodology, we here present a new risk assessment method which better fulfils requirements of validity and reliability. The method contains fewer, more robust and fixed input parameters than today. Since uncertainty is high and the amount of validating data is low, the method is focused on relative rather than absolute risks, and include both prospective and retrospective risk assessment elements that are applied in concert. In this way, the new method meets the legal requirements of being scientific and to address uncertainty in a comprehensive way.

## Reduction strategies of micropollutants from large and small-scale sewage water facilities (II)

## 510

### Enzymatic degradation of hormones and EDCs in wastewater - a novel

## biotechnological approach

D. Becker, Goethe University Frankfurt / Aquatic Ecotoxicology; R. Schoevaart, Chiralvision; O. Couillerot, J. De Gunzburg, DaVolterra; M. de Cazes, J. Sanchez-Marcano, M. Belleville, Institute Européen des Membranes; S. Insa, Institute for Water Research ICRA; M. Llorca, IDAEA, CSIC; S. Rodriguez-Mozaz, Institute for Water Research (ICRA) / Water Quality; D. Barcelo, IQAB-CSIC / Institute for Environmental Assessment and Water Research; J. Oehlmann, Johann Wolfgang Goethe-Universität Frankfurt / Aquatic Ecotoxicology; M. Wagner, Goethe University Frankfurt / Aquatic Ecotoxicology  
Micropollutants (e.g., pharmaceuticals, hormones) are continuously released into the environment in low concentrations. Concerns have been raised regarding their toxicity and their limited degradation during conventional wastewater treatment. The EU-project ENDETECH develops a novel biotechnological approach to degrade micropollutants. Specific enzyme libraries were screened to identify promising candidates that remove these pollutants effectively. The enzymes are optimized and immobilized for an application in bioreactors. Priority targets of enzyme selection are antibiotics, hormones, and EDCs. Every step within the project is accompanied by *in vitro* bioassays for endocrine effects (estrogenicity, androgenicity) and mutagenicity. This is to evaluate the degradation of effects and assess potential new effects caused by generated transformation products. Degradation of target compounds was also monitored by on-line SPE-LC-MS-MS and data processed using *TraceFinder* 3.1. Several enzymes were discovered; and those ones from fungi (i. e., laccases from *T. versicolor*, *M. thermophila*) were the most promising, especially regarding EDC-degrading activity. The degradation of antibiotics after lab-scale enzymatic treatment in buffered water was already successful, such as tetracycline and erythromycin which were degraded by 78% and 52%, respectively after 18 h. The next major aspect is a proof of concept, i. e. the feasibility of enzymatic treatment under "real world" conditions in wastewater. First experiments with endocrine active hospital wastewater showed a significant reduction of androgenicity and estrogenicity. For example the latter was reduced by 80% after 24 h laccase treatment. Furthermore we investigated the degradation of mixtures of known endocrine disrupting chemicals. They were conducted in ultrapure water and in real wastewater. The degradation of EDCs with laccase is feasible, even at very low enzyme concentrations. The degradation by immobilized enzymes is faster compared to free enzyme but this tendency is superimposed by the adsorption of the carrier. Compared to the mixtures of known EDCs, we did not observe a degradation of unknown EDCs in wastewater this time. A solution would be a higher enzyme activity. These findings demonstrate that the enzymatic treatment technology can be an efficient and eco-friendly alternative or addition to existing technologies.

## 511

### Ozonation: a way to reduce antivirals in wastewater effluent?

G. Fedorova, University of South Bohemia in CB / Faculty of Fisheries and Protection of Waters South Bohemian Research Center of Aquaculture and Biodiversity of Hydrocenoses Vodňany Czech Republic; R. Grabic, University of South Bohemia in CB / Faculty of Fisheries and Protection of Waters, South Bohemian Research Center of Aquaculture and Biodiversity of Hydrocenoses; H.S. Söderström, Umeå University  
G. Fedorova<sup>1,2</sup>, R. Grabic<sup>2</sup>, H. Söderström<sup>1</sup> <sup>1</sup>Department of Chemistry, Umeå University, Sweden <sup>2</sup>University of South Bohemia in Ceske Budejovice, Faculty of Fisheries and Protection of Waters, South Bohemian Research Center of Aquaculture and Biodiversity of Hydrocenoses, Zatisi 728/II, 389 25 Vodňany, Czech Republic **Keywords:** Antivirals; ozonation; high resolution mass spectrometry; transformation products. Antivirals have recently been widely detected in wastewaters and surface waters, particularly during the seasonal and pandemic outbreak of influenza virus. Concerns have been raised that once in the environment, they can induce resistance to antivirals in the influenza viruses. An antiviral resistant virus in worst case can be transmitted to humans. Neuraminidase inhibitors (NAIs) are antivirals used for treatment of influenza A and B. Oseltamivir (Tamiflu®) is the most commonly used NAI; at least 75% is metabolized to the active metabolite oseltamivir carboxylate (OC) in the human body. Zanamivir (Relenza®) (Za) is excreted almost 100% unchanged from treated humans. Amantadine (symmetrel®) (Am) is an antiviral that is no longer recommended for treatment of influenza but is still used in, for instance, Asia. Previous studies have shown that these antivirals are not well removed or degraded by conventional wastewater treatment. In this study, the removal of the three antiviral compounds Am, OC and Za and the formation of their transformation products (TPs) during wastewater ozonation, were studied. Secondary biological treated effluents from two wastewater treatment plants in Sweden with target compounds at the concentration 20 µg L<sup>-1</sup> were treated. The removal profile of target antivirals as well as formation of their TPs was studied by liquid chromatography/high resolution mass spectrometry. Two hours of ozone exposure at a concentration of 148 mg ozone/10 mg TOC led to complete removal of the three antiviral drugs. Two, five and one TPs were identified for Am, OC and Za, respectively. The increasing of TPs concentration followed the decrease of concentration of target compounds. Patterns for the TPs formation did not differ between the two wastewaters. **Acknowledgements** The authors gratefully acknowledge the Swedish Research Council Formas, Ozone Tech Systems OTS AB, GlaxoSmithKline Country and Merck Millipore Sweden, CENAKVA CZ.1.05/2.1.00/01.0024 project, and the LO1205 project with financial support

### UV disinfection of secondary wastewater effluents: Effect of irradiation time on the removal of organic micropollutants

L. Paredes; J.M. Lema, F. Omil, University of Santiago de Compostela / Chemical Engineering; M. Carballa, University of Santiago de Compostela

The presence of organic micropollutants in receiving water bodies from its incomplete removal during the conventional wastewater treatment constitutes a potential risk for aquatic ecosystems. Although UV irradiation is an advanced treatment technology employed in wastewater treatment plants (WWTPs) to reduce pathogenic activity, some works have demonstrated its efficiency to remove certain organic micropollutants. However, the application of UV photolysis can generate, in some cases, intermediate products more toxic than the parental compound. Therefore, the main objective of this work was to assess the effect of UV irradiation time on the removal of micropollutants from secondary wastewater effluents, taking into account, the toxicity and the disinfection of treated effluent. The influence of background effluent matrix and temperature on the photodegradation of the selected micropollutants was also evaluated. For this propose, three secondary effluents from small and medium scale WWTPs (14,000 inh-eq; 184,000 inh-eq and 132,300 inh-eq, respectively) were tested. All experiments were carried out in a UV laboratory reactor provided with a low pressure lamp (nominal power 15 W and monochromatic radiation at 254 nm) in batch mode. The ecotoxicity of the obtained samples was evaluated employing the bacteria *Vibrio fischeri* while the disinfection efficiency of UV treatment was measured through the determination of coliforms and *Escherichia coli*. According to the results obtained, UV irradiation is considered an effective treatment technology to reduce the concentration of the selected organic micropollutants in secondary wastewater effluents, even those recalcitrant compounds, such as carbamazepine and diclofenac (removal efficiencies obtained above 57% and 99%, respectively, after 30 min of treatment). The effects of background effluent matrix and temperature on the photolysis of the studied micropollutants were not observed in this work. The optimization of UV exposure time was considered a key factor to ensure the complete photodegradation of the selected organic micropollutants, thus avoiding the possible appearance the intermediate products more toxic than parental compounds.

## 513

### Removal of sulfamethoxazole via ammonia oxidizing bacteria co-metabolism

E. KASSOTAKI, ICRA / Technologies and Evaluation; G. BUTTIGLIERI, Catalan Institute for Water Research ICRA / Technologies and Evaluation; I. RODRIGUEZ-RODA, Universitat de Girona and ICRA / LEQUiA; M. PIJUAN, Catalan Institute for Water Research ICRA / Technologies and Evaluation

The sulphonamide antibiotic sulfamethoxazole (SFX) has been frequently detected in wastewater treatment plants (WWTP) and surface waters. Up-to-date investigations pertaining to SFX elimination are marked by inconsistent results. Advanced treatment processes are promising compared to the conventional ones, but limitations are posed due to maintenance and operational costs. Hence, biodegradation is considered to be one of the most promising technologies due to its low cost and its potential for complete micropollutants removal. Previous studies have demonstrated that the removal of pharmaceutical compounds can be enhanced in nitrifying systems, due to the activity of ammonia oxidizing bacteria (AOB) which could co-metabolize these compounds using one of its key enzymes, ammonia monooxygenase (AMO), but studies regarding SFX removal by enriched AOB cultures are currently lacking. This study explores the biodegradation capacity of an enriched AOB culture (>80% of the microbial population belonging to the AOB group) present in a nitrification sequencing batch reactor treating reject wastewater (1g N-NH<sub>4</sub>/L) towards SFX, under different conditions. The aim was to demonstrate if AOB was able to degrade SFX and if so, under which conditions. Batch experiments were performed in duplicates using enriched AOB biomass withdrawn from the nitrification SBR, in order to assess: i) the effect of the nitrifying activity (measured as nitrification rate), ii) the effect of ammonia starvation, iii) the role of AMO enzyme and iv) the contribution of the heterotrophic activity (addition of acetate), on SFX degradation. Three different NH<sub>4</sub><sup>+</sup> loading rates providing different ammonia oxidation rates in the batch reactor (0.65, 0.33 and 0.16mg/min) were tested, while the initial mass of SFX, ATU and acetate that were spiked into the system was 100µg, 25mg and 100mg, respectively. Additionally, and for each of the tests, an abiotic control experiment was conducted to exclude any chemical reaction. In all tests, pH and temperature were controlled and aerobic conditions were ensured. The results showed that the enriched nitrifying biomass removed SFX via co-metabolism, producing one of its known metabolites (4-Nitro-SFX) but at a lower concentration. This removal was enhanced when increasing nitrifying activity, reaching values around 80%. Moreover, it was found that the activity of the AMO enzyme was directly linked to SFX degradation.

### Biotransformation of organic micropollutants in the methanogenic step of sewage sludge anaerobic digestion: experimental results and modelling

L.G. Gil, University of Santiago de Compostela / Department of Chemical Engineering; M. Carballa, University of Santiago de Compostela; J.M. Lema, University of Santiago de Compostela / Chemical Engineering

Organic micropollutants (OMCs) in sewage treatment plants tend to sorb in suspended solids. Sewage sludge is mainly used as biosolid; consequently, to avoid the release of micropollutants into agricultural land they might be removed during sludge anaerobic digestion (AD). AD is a complex process constituted by various steps that might have different influences on the removal of OMCs. Therefore, in order to increase the removal efficiency of these compounds, it is necessary to understand their behaviour in each step. This study aims to investigate the fate and biotransformation of usually detected micropollutants in sewage sludge during methanogenesis, which is a key step in AD. To this end, kinetic experiments in a continuously stirred methanogenic digester were performed. The fate of an initial pulse of galaxolide (HHCB), tonalide (AHTN), ibuprofen (IBP), naproxen (NPX), sulfamethoxazole (SMX), trimethoprim (TMP), erythromycin (ERY), fluoxetine (FLX), carbamazepine (CBZ), triclosan (TCS), estrone (E1), 17β-estradiol (E2) and 17α-ethinylestradiol (EE2) was followed during time. The behaviour of the added OMCs was straight related to its solid-liquid partition coefficient (K<sub>d</sub>); thus, some of them remained mainly in the liquid phase, meanwhile others sorbed into solids. In addition, experimental results suggest that biotransformation mechanisms could take place at different extents in the liquid and solid phase, depending on the OMC. Total concentrations were adjusted to a proposed biotransformation kinetic model, which seems to be appropriate to describe the behaviour of OMCs during methanogenesis and to quantify the capability of methanogenic biomass to biotransform OMCs. Several biotransformation kinetic models are being developed in order to simulate accurately the fate in both the liquid and solid phase of methanogenic sludge. In terms of removal, this study argues that methanogenesis has a high impact in the removal of several OMCs, being a key step in the biotransformation of SMX, TMP, EE2, NPX, FLX and TCS. Accordingly, anaerobic digesters in sewage treatment plants should maximize the methanization of the feeding sludge in order to increase the removal of present OMCs.

## 515

### Is combination of UVC and H2O2 effective to remove estrogens from water?

B. CEDAT, COMAPINSA Lyon / LGCIE

Water pollution is of major concern in France. Half of water resources was still not meeting the European quality requirement in 2012. Moreover, recent progresses in analytical chemistry have identified numerous micropollutants in Wastewater Treatment Plant (WTP) discharge coming from urban, agricultural or industrial activities. Amongst hundreds of micropollutants, estrogenic compounds were shown to cause endocrine disruption in fish at very low doses and suspected to impact human fertility. Therefore, WTP upgrade is needed to eliminate them. Advanced oxidation processes were shown to eliminate up to 80% of targeted micropollutants. However small and middle sized WTP (< 10000 inh. eq.) are poorly equipped despite representing 90% of the overall French WTP. Advanced Oxidation Processes (AOPs), based on the generation of highly reactive hydroxyl radicals for the unselective oxidation of chemical pollutants can be an adequate solution. This study aims at developing a cost-effective UV/H<sub>2</sub>O<sub>2</sub> advance oxidation process (AOP) in order to reduce estrogenic activity in small and middle sized WTP discharge. Experiments were conducted at 20°C with a UV reactor (COMAP WT) and a 55W low pressure lamp (Phillips) emitting at 254nm. Local tap water (Lyon, France) was added in a 50L glass tank and circulated at a flow rate of 40L/min in a closed system. A mixture of Estrone (E1), β-Estradiol (E2), and α-ethinyl estradiol (EE2) was added at 5µM and degradation rates were measured during either UV (photolysis) or UV + H<sub>2</sub>O<sub>2</sub> treatments over 60min. Samples were taken every 10 minutes and analyzed by HPLC. Three different concentrations of H<sub>2</sub>O<sub>2</sub> were tested: 10, 50 or 100mg/L. First results showed a low degradation of E2 and EE2 by photolysis after 60 min exposure (< 20%) in tap water but E1 was well degraded (up to 80%). When adding H<sub>2</sub>O<sub>2</sub>, every hormones degradation rate were significantly improved. Degradation rate reached 80% for E1 and 90% for E2 and EE2 at 10mg/L H<sub>2</sub>O<sub>2</sub>. Total degradation was both reached with 50mg/L and 100mg/L H<sub>2</sub>O<sub>2</sub>. These results pointed out that estrogens removal can be highly enhanced by combining UV and H<sub>2</sub>O<sub>2</sub>. Further investigations are needed to test this process on effluents at environmental concentrations.

### Invertebrates as indicators for chemical stress in wastewater-influenced stream systems: Toxic and endocrine effects in gammarids in two tributaries of Lake Constance, Schussen and Argen

K. Peschke, H. Köhler, Tübingen University / Animal Physiological Ecology; R. Triebelskorn, University of Tuebingen / Animal Physiological Ecology

Anthropogenic pollutants released into the environment can cause short- or long-term adverse effects in aquatic organisms. Unfortunately, conventional wastewater treatment plants (WWTPs) are not, or only partially able to eliminate micropollutants during wastewater purification. Activated carbon filtration is one possibility to reduce micropollutants from the water cycle. Its efficiency with respect to ecosystem health, however, is far from being understood. The current work is integrated into the BMBF project "SchussenAktivplus", an ecotoxicological research programme conducted in two tributaries of Lake Constance, the rivers Schussen and Argen, Southern Germany. At the Schussen, an activated carbon filter has been established at the WWTP Langwiese, Ravensburg,

in winter 2013. Our part of the project focuses on assessing the overall health status of gammarids in the rivers Schussen and, in parallel, at the river Argen as a reference river. Two gammarid species were investigated in the present study: *Gammarus pulex* and *Gammarus roeseli*. Gammarids are excellent monitoring organisms, since they are widely distributed, occur in high abundances, are characterized by a rather short generation time, and are highly sensitive to pollutants. Samples were taken at different sites at the Schussen upstream and downstream of the WWTP, and in parallel, at the Argen river. Sampling took place several times prior and subsequent to the implementation of the activated carbon filter. Analyses of heat shock protein (hsp70) levels allowed us to draw conclusions about the general stress status of organisms based on proteotoxicity. Furthermore, the gammarid populations from all sites were investigated with respect to sex ratio, parasitism rate and fecundity. Based on the results of our study we conclude that the gammarids' health was impaired by the effluent of the WWTP Langwiese prior to the upgrading. Subsequent to its upgrade, however, organisms collected at the downstream site did not differ any more from gammarids collected upstream of the WWTP with respect to the investigated health parameters. Therefore, the efficiency of the activated carbon filter to eliminate toxic and endocrine chemicals from the effluent seems to be obvious. However, since results obtained subsequent to the upgrading are based on a dataset for a single year only, annual specific influences cannot be excluded. Further investigations are therefore required to strengthen the results.

## 517

### **Sediment ecotoxicity in Iberian basins: toxicity bioassays and the Toxic Unit approach as complementary assessment tools**

N. De Castro, Departament d'Ecologia; M. Kuzmanovic; N. Roig, Universitat Rovira i Virgili; J. Sierra, Universitat Rovira i Virgili / Soil Science Unit; A. Ginebreda, CSIC - Spanish National Research Council / Department of Environmental Sciences; D. Barcelo, IQAB-CSIC / Institute for Environmental Assessment and Water Research; M. López de Alda, Institute of Environmental Assessment and Water Research IDAEA CSIC / Environmental Chemistry; S. Perez, IDAEA-CSIC / Environmental Chemistry; M. Petrovic, ICRA; Y. Pico, University of Valencia / Medicine Preventive; M. Schuhmacher, Rovira i Virgili University / Chemical Engineering; I. Muñoz, University of Barcelona / Ecology

The quality of sediment is critical to the health of an aquatic ecosystem. Sediments can accumulate high diversity of pollutants, which can disrupt biological communities and alter the ecological status of ecosystems. Different bioassays have been developed in the last decades in order to evaluate the effects of the exposition of organisms to pollutants in sediment. These tests complement the information of the biological quality and the chemical characterization of the sediment carried out in monitoring programs. Therefore, the aim of this study was to analyse the sediment ecotoxicity in four Iberian rivers based upon the results of chemical characterization, considering priority and emerging pollutants and biological responses. A battery of acute and chronic toxicity tests covering different trophic levels were conducted to evaluate the toxicity of pore water and whole sediment. The studied basins were the Ebro, the Llobregat, the Júcar and the Guadalquivir, and the test organisms were *Vibrio fischeri*, *Pseudokirchneriella subcapitata*, *Daphnia magna* and *Chironomus riparius*. Additionally, a broad spectrum of priority and emerging pollutants (EDCs, pesticides, PhACs, perfluorinated compounds, flame retardants, persistent organic pollutants and illicit drugs) were analysed in the sediment matrix. The Toxic Unit (TU) approach was applied to discern which compounds would explain the organism responses. EBR1 presented the lowest EC50 for *V. fischeri*, followed by EBR2 and GUA4. 20% mortality was found in EBR2, EBR3 and LLO5 for the *D. magna* test, and in JUC2 and JUC6 mortality levels were higher than 30%. The mortality of *C. riparius* was over 30% in EBR1, coinciding with the results found with *V. fischeri*. Lower growth rates respect to the control were detected in LLO5 ( $p < 0.05$ ). According to these results, the sediments that presented highest ecotoxicity were EBR1, EBR2, EBR5, GUA4, LLO5 and JUC2. The Llobregat river presented the highest TUs levels. GUA1 and EBR1 also presented high TUs levels. The main contribution to TUs were pesticides, mainly chlorpyrifos. Significant correlations were found between *C. riparius* endpoints and the *D. magna* TUs of PhACs, EDCs, illicit drugs and pesticides. These results confirm that the battery of toxicity tests together with the TU approach could be a good complementary tool for the determination of the ecological quality of these four studied river sediments.

## 518

### **The comparability of toxicity endpoints in bees**

P.J. Holder, University of Exeter / Biosciences; C.R. Tyler, Biosciences College of Life and Environmental Sciences; J. Cresswell, Exeter University

Convenient model species are regularly used in pesticide risk assessments to evaluate toxic effects for groups of species. For example, risk assessments for pesticide effects on pollinators are currently carried out mainly on honeybees. Many bee species however are exposed to pesticides applied to crops, with a wide range of negative effects, and there is doubt as to whether honeybees are representative of all bee species. Also, current risk assessments mainly focus on short-term, lethal endpoints. Here we used the response-response relationship to determine whether sensitivity to fipronil differs between two bee species (*Bombus terrestris* and *Apis mellifera*) and several endpoints for toxicity testing. We plotted the responses of bees exposed to identical doses of fipronil under laboratory

conditions against one another to determine whether different species and endpoints are equally sensitive. Bumblebees were more sensitive than honeybees to dietary fipronil, up to  $125 \mu\text{g L}^{-1}$ , for the endpoints of longevity and feeding. Fecundity was found to be more sensitive than both mortality and pollen feeding as an endpoint of bumblebees exposed to dietary fipronil, up to  $1.28 \mu\text{g L}^{-1}$ , within queenless microcolonies. In conclusion, the bumblebee (*Bombus terrestris*) would make a better sentinel species than the honeybee (*Apis mellifera*) for determining toxic effects on a social pollinator due to its increased sensitivity to toxicants across lethal and sublethal endpoints. Among the endpoints we tested, bumblebee fecundity would make a suitable endpoint for regulatory testing due to its higher sensitivity to toxicants. Fecundity is an ecologically realistic endpoint which is reduced at field realistic concentrations of fipronil and is demographically relevant to protection goals.

## 519

### **Identification of trans- and cis-eQTLs in Lead-treated Drosophila Model**

W. Qu, Wayne State University / Pharmacology; R. Pique-Regi, Wayne State University / Center for Molecular Medicine and Genetics; D. Ruden, Wayne State University / Department of ObGyn

Lead poisoning has long been a major public health issue globally. In order to better understand how lead plays a role as a neurotoxin, we utilized the *Drosophila melanogaster* model to study the genetic effects of lead exposure during development and identify the lead-sensitive genes. Our group utilized the eight-way *Drosophila* recombinant inbred lines (RILs) from the *Drosophila* Synthetic Population Resource (DSRP, details in <http://wfitch.bio.uci.edu/~dspr/>) and conducted RNA-seq and expression quantitative trait loci (eQTL) analyses to validate our previously identified trans-eQTLs using microarrays (Ruden et al., 2009). What we have found is that approximately 2/3 of total cis-eQTLs were shared in both control and Pb-treated data. However, many of the trans-eQTLs found in control samples shifted their positions after treatment with lead. Cis-eQTLs are regulatory regions that are genetically linked to the gene, whereas trans-eQTLs are regulators that are not genetically linked to the gene. The shifting of entire trans-eQTL networks in the presence of lead was an unexpected finding in our original study that we replicated in the current study. Using RNA-seq analysis also helped narrow down each trans-eQTL network from the previous 5Mb to within 1Mb, which makes future experimental validation and the identification of causative single nucleotide polymorphisms (SNPs) in the trans-eQTLs possible. A future advantage of RNA-seq over microarrays is that we can also identify splicing QTLs (sQTLs), which are SNPs that regulate alternative mRNA splicing. The identification and validation of both trans-eQTLs and sQTLs SNPs will be the basis of our future research on this project.

## 520

### **Ecotoxicological effects of post-fire runoffs on aquatic invertebrate detritivores**

F.A. Carvalho, University of Minho / CBMA Center of Molecular and Environmental Biology Biology Department University of Minho Campus of Gualtar Braga; A. Pradhan, University of Minho / Department of Biology; N. Abrantes, University of Aveiro / CESAMDAO; C. Pascoal, F. Cassio, University of Minho / Centre of Molecular and Environmental Biology (CBMA), Department of Biology

Mediterranean forests are highly susceptible to wildfires, which can cause several impacts not only on burnt areas, but also on adjacent ecosystems. The washout of ashes from burnt areas by surface runoff may transport to streams pyrolytic substances, including polycyclic aromatic hydrocarbons and metals, which can be toxic to aquatic organisms. However, there is still a lack of knowledge on the impacts of post-fire runoff on stream biota. Here, we used aqueous extracts from wildfires obtained in different areas (pine trees, high severity; eucalypt trees, high severity and a stream) in Macida (Sever do Vouga, Portugal) to evaluate their effects on the feeding behavior and biochemical responses of the invertebrate detritivore *Allogamus* sp. The feeding activity was assessed by exposing animals for 20 days to increasing concentrations (0, 50, 75 and 100%) of aqueous extracts and allowing them to feed on leaves previously colonized in a stream by microorganisms. To assess the biochemical responses, we measured the oxidative stress biomarkers glutathione peroxidase, glutathione reductase, glutathione-S-transferase, and the neuronal stress biomarker cholinesterases, in invertebrates exposed for 96 hours to increasing concentrations of the aqueous extracts. The invertebrate feeding rate decreased to 10% comparing to control when animals were exposed to the highest extract concentration of wildfire aqueous extracts from the eucalypt plantation. Severe inhibition of the feeding rate was also found after exposure to wildfire extracts from the pine tree plantation (decreased to 18% at 75% extract concentration). Stream extracts had the less severe effects on the invertebrate feeding rate, which was reduced to 50% at the highest concentration. After exposure to the aqueous extracts, the activity of oxidative stress enzymes increased significantly in a concentration-dependent manner, while cholinesterase activity decreased. Overall, results suggested that post-fire runoff affects the behavior and physiology of invertebrate detritivores with potential impacts to their ecological role in streams. ### Microfluidic Lab-on-a-Chip Technologies - biocybernetic systems for aquatic in situ ecotoxicology biotests

D. Włodkowiec, RMIT University / School of Applied Sciences

A major hurdle to widespread deployment of high-throughput aquatic ecotoxicity tests is the lack of enabling and automated analytical platforms. As such nearly all currently performed experiments are done in multiwell microtitre plates or flasks and require laborious, time-consuming manual manipulation of specimens and solutions. Furthermore, static culture conditions often found in ecotoxicity testing can lead to a significant bias in toxicity studies due to e.g. drug adsorption to the surfaces and also secondary effects from the secreted by test organisms metabolites. These major shortcomings have not been addressed as yet, and as a result high-throughput analysis in ecotoxicology is still non-existent. The above mentioned drawbacks can, however, be addressed from an engineering standpoint by an emerging field of microfluidic Lab-on-a-Chip (LOC) technologies combined with sophisticated optoelectronic sensors. The up-and-coming microfluidic Lab-on-a-Chip (LOC) technology and micro-total analysis systems ( $\mu$ TAS) are arguably the most promising platforms to address the inherent complexity of biological systems with massive experimental parallelization and 2D+time analysis. Microfluidics is uniquely aimed at manipulating liquids in networks of microchannels where fluids exhibit different physico-chemical properties, when compared to their behaviour at the macro-scale. LOC has already been widely heralded as an emerging technology with a multitude of applications in experimental cell biology and drug discovery. However, implementation of microfluidic systems in ecotoxicology is virtually non-existent. Our pioneering work provides a foundation for automated high throughput ecotoxicity biotests using innovative Lab-on-a-Chip technologies. We are convinced that microfluidic technologies can provide new vistas for high-throughput ecotoxicity studies on selected aquatic test species. A key advantage of microfluidic systems as compared to conventional static "Petri dish" testing is the miniaturization and automation of analysis and special emphasis on analysis performed under continuous microperfusion. We anticipate that rapid development, validation and adaption of miniaturized fluidic technologies will bring us a step closer to realization of full laboratory automation in ecotoxicology.

### Multistress in aquatic environments: the big picture (III)

#### 522

#### Influence of temperature on the tolerance capacities of phototrophic and heterotrophic biofilm communities to copper

A. Lambert, Irstea Lyon; A. Dabrin, Irstea centre de Lyon Villeurbanne / UR MALY; S. Morin, Irstea / UR EABX; J. Gahou, Irstea Lyon; S. Pesce, Irstea / UR MALY

Agricultural rivers are highly affected by metal pollution, with copper (Cu) being frequently detected and impacting aquatic organisms. In lotic ecosystems, periphytic biofilms assume key ecological functions such as primary production and nutrient cycling. These microbial assemblages are formed by phototrophic and heterotrophic communities which are the first to interact with dissolved substances, including Cu. Chronic exposure of biofilms to Cu can induce a succession of phototrophic and heterotrophic species resulting in a replacement of the sensitive species by more tolerant ones, thus leading to an increase in the tolerance of the microbial communities to this toxicant (concept of pollution-induced community tolerance, PICT). However, the pollution of surface waters and the resulting ecotoxicological effects must be viewed in a context of global change since aquatic systems are generally subjected to multi-stress conditions. Given the increase in extreme climatic events due to climate change, acute variations in temperature may represent an environmental stressor influencing microbial communities. Indeed, even if effects of Cu on microbial communities are relatively well known, there is a lack of data about the possible influence of temperature on the tolerance capacities of biofilm to copper. Accordingly, the present study aimed to evaluate in microcosms the influence of temperature on the tolerance level of microbial biofilm communities to Cu. Natural summer communities, collected in a 18°C stream water, were subjected for 4 weeks to 3 thermal conditions (18°C, 23°C and 28°C) in presence or not of Cu. Tolerance levels of phototrophic and heterotrophic communities were evaluated using short-term toxicity tests targeting photosynthetic (yield) and enzymatic activities ( $\beta$ -glucosidase and leucine-aminopeptidase), respectively. At the initial river temperature (18°C), our results confirmed the tolerance increase to Cu after chronic exposure of both phototrophic and heterotrophic communities. While the increase in temperature only had a limited effect on the tolerance level of communities pre-exposed to Cu, our results showed a great influence of temperature on the Cu tolerance level of both phototrophic and heterotrophic communities that were not pre-exposed to Cu. It reveals that temperature is a primordial factor to take into account in the assessment of tolerance capacities of biofilms to metal stress, especially when using PICT approaches.

#### Salinisation effects on coastal freshwater ecosystems due to climate changes

C. Venâncio, Biology; B.B. Castro; N. Abrantes, University of Aveiro / CESAMDAO; E. Anselmo, CESAM University of Aveiro; S. Antunes,

University of Oporto / Biology; M. Moreira-Santos, University of Coimbra, IMAR-CMA / Department of Life Sciences; A.M. Soares, Universidade de Aveiro / Department of Biology and CESAM; R. Ribeiro, University of Coimbra; I. Lopes, University of Aveiro / CESAM Biology Department

Recent projections of the International Panel for Climate Change comprise among others awareness regarding global sea level rise. Though some knowledge exists on the impacts of salinity on freshwater ecosystems, a considerable uncertainty on salinisation effects to these ecosystems still remains, denoting the need for further detailed investigations on this issue. This work intended to contribute for a better prediction of the effects provoked by salinisation to freshwater coastal ecosystems. For this, four specific objectives were delineated: (i) determine the ecological receptors at more risk, (ii) determine the ability of freshwater species to acclimate to salinity, (iii) determine if an association exists between tolerance to salinity and other chemicals, and (iv) assess the influence of salinity in interspecific relationships (competition). To attain specific objective (i) and (ii), lethal and sublethal monospecific assays were performed by exposing species, from different trophic levels, to increased salinities (due to natural seawater and NaCl) before and after being acclimated to low levels of salinity. To address specific objective (iii) six clonal lineages of *Daphnia longispina* were exposed to lethal levels of increased salinity and of four metals (copper, zinc, cobalt, chromium), to study the associations between the sensitivity to salinity and metals. To tackle specific objective (iv) microcosms experiments were done with two species of microalgae exposed to increased salinity scenarios under the absence and presence of inter-species competition. Obtained results suggest that, in a test-screening phase, NaCl could be used as a surrogate of seawater effects on freshwater biota. As well, when conducting predictive risk assessment of salinity effects the use of zooplankton species is suggested as they revealed to be amongst the most sensitive group to this stressor. No association between salinity and different metals was observed. However, some clonal lineages of *D. longispina* exhibited an inverse tolerance to these two types of chemicals, which may denote a higher risk of extinction of natural populations, previously exposed to metal contamination, if subsequent exposure to increased salinity occurs. Finally, this study suggests that salt stress can influence community composition by disrupting competitive relationships. In this study, *R. subcapitata* lost the competitive advantage over *C. vulgaris* when exposed to increased salinity.

#### 524

#### Effect evaluation in multiple contaminated sites - a case study confirmed by a microcosm approach

S. Rotter, Helmholtz Centre for Environmental Research / Department of EffectDirected Analysis; M. Schmitt-Jansen, UFZ - Helmholtz Ctre Environm. Research / Department of Bioanalytical Ecotoxicology

Multiple contaminations of diverse natural and anthropogenic stressors essentially complicate the link between exposure of site-specific stressors and effects on freshwater organisms. The concept of pollution-induced community tolerance (PICT) is a promising tool for site-specific effect assessment which might overcome this limitation by quantifying community tolerance. In this study, PICT was applied as diagnostic tool for the effect confirmation of a former effect-directed analysis (EDA) study on sediments, which revealed three phytotoxic compounds in a multiple contaminated site. In a case study, the impact of three site-specific, phytotoxic compounds on periphyton was investigated *in situ*. Periphyton was cultivated at a reference (R-site) and at a polluted site (P-site), previously analysed by EDA. The sensitivity of R- and P-site communities to prometryn, tributyltin and N-phenyl-2-naphthylamine was quantified by measuring the inhibition of photosynthesis. Biomass, algal class- and diatom composition of periphyton was analysed and exposure of contaminants detected. The study revealed that prometryn was the only toxicant, effecting local periphyton. However, the polluted site showed a rather high conductivity of 2000  $\mu$ S  $\text{cm}^{-1}$ , arousing the question of joint effects from prometryn and high ionic loads. Therefore, the possible interaction of prometryn and high ionic loads was investigated in a microcosm study under standardised conditions. Joint effects of combined stress were found at ionic loads higher than found in the field. Therefore, detected effects on periphyton tolerance in the field are most probably based on the exposure to prometryn only. In conclusion, the PICT concept allows an effect-based *in situ* hazard confirmation and should be considered for hazard confirmation of phytotoxic contaminants for environmental risk assessment.

#### 525

#### Is the toxicity of pesticide mixtures on river biofilm accounted for solely by the major compounds identified?

S. KIM TIAM, INRS - Eau, Terre et Environnement; S. Morin, Irstea / UR EABX; B. Bonet, Institute of Aquatic Ecology / Institute of Aquatic Ecology; H. Guasch, Institute of Aquatic Ecology; A. Feurtet-Mazel; M. Eon, Irstea / UR EABX; P. Gonzalez, Géochimie et Ecotoxicologie des Métaux dans les systèmes Aquatiques GEMA team UMR CNRS Université Bordeaux; N. Mazzella, Irstea Comparative effects of long-term exposure to Polar Organic Chemical Integrative Sampler (POCIS) extracts (PE) and to a reconstituted mixture based on the major compounds quantified in the PE were evaluated on river biofilm communities. The study aimed to characterize the effects of long-term and low-dose exposure to pesticides on natural biofilm communities and to evaluate if the effects due to PE exposure could be explained solely by the major compounds identified in the

extracts. Biofilms from an uncontaminated site were exposed in artificial channels to realistic environmental concentrations using diluted PE, with the 12 major compounds quantified in the extracts (Mix) or with water not containing pesticides (Ctr). Significant differences between biofilms exposed to pesticides or not were observed with regard to diatom density, biomass (dry weight and ash-free dry mass), photosynthetic efficiency (F<sub>psII</sub>) and antioxidant enzyme activities. After 14 days of exposure to the different treatments, the observed trend towards a decrease of mean diatom cell biovolumes in samples exposed to pesticides was related to the control biofilms' higher relative abundance of large species like *Cocconeis placentula* or *Amphora copulata* and lower relative abundance of small species like *Eolimna minima* compared to the contaminated ones. Principal component analyses clearly separated contaminated (PE and Mix) from non-contaminated (Ctr) biofilms; on the contrary, the analyses did not reveal separation between biofilms exposed to PE or to the 12 major compounds identified in the extract.

526

#### **Depict the mechanisms governing parasite communities within *Dreissena polymorpha*: stochastic, biotic interaction or driven by contamination?**

L. Minguez, UPV Metz, CNRS UMR 7146 / LIEC CNRS UMR; S. Devin, LIEC - Université de Lorraine - CNRS / LIEC CNRS UMR; S. Pain-Devin, Université de Lorraine - UL / LIEC CNRS UMR; L. Giamberini, Université de Lorraine, CNRS UMR 7360 / LIEC CNRS UMR

Parasitic ubiquity implies that every organism can be the host for a "cocktail" of parasites. Due to their incredible diversity, their omnipresence in the environment, the key roles they play in host population and community structures and also in ecosystem functioning, parasites can no longer be ignored. Up to now studies on host-parasite interactions have mainly focused on systems with one host infected by one parasite species. The organisms, hosts or parasites, used for coinfection investigations all displayed economic, veterinary and/or medical interests. In this context, freshwater bivalves were poorly studied. By using the zebra mussel (*Dreissena polymorpha*) as model host, the purpose of this talk is to explore: (1) the drivers of coinfections, do parasites infect their host randomly? Do parasite assemblages depend on the environmental quality? and (2) the effects of coinfections on host physiology compared with single parasite infections. These parasite communities infecting zebra mussels were studied at nine stations located in the northern half of France and three in the United States of America on the Mohawk River (New York State). Both community structures, physiological effects on host and environmental quality (i.e. contamination levels) were studied. In order to explore the drivers of coinfection, the first step was to define whether the coinfection differed according to the host gender. Then, we seek for facilitation, competitive exclusion or stochastic phenomenon between parasites through the elaboration of a null model of coinfection. The effects of parasitism on host were assessed on several cellular biomarkers commonly used in ecotoxicological studies. The coinfection cases raised concerns in 20.34% of sampled zebra mussels. Among infections with two parasite species, the association between ciliates *Ophryoglena* spp. and RLO bacteria represented 65% of these coinfections. Results of null models show that the presence of different parasite species within a same zebra mussel host is a stochastic phenomenon. However, the deviation from this pattern could be explained, at least partly, by differences in contamination levels (particularly in zinc and to a lesser extent nickel). Even if these coinfections will be only due to chance, they deserve more attention. Indeed, coinfections can significantly modify the effects than each parasite species has on their host, and thus lead to stronger biological effects.

527

#### **Ocean acidification modifies the effect of antibiotics on natural marine bacteria communities**

T. Sircar, University of Gothenburg / Dept of Biological and Environmental Sciences; M.E. Asplund, University of Gothenburg / Biology and Environmental Science; S. Dupont, University of Gothenburg / Department of Biological and Environmental Sciences; M.E. Granberg, Norwegian Polar Institute / Research World oceans are becoming more acidic as they continuously absorb 25-30% of the increasing amounts of atmospheric CO<sub>2</sub>. Since pre-industrial times the average ocean surface water pH has decreased by 0.1 units, corresponding to a 26% increase in hydrogen ion concentration. Given that atmospheric CO<sub>2</sub> levels reach the predicted 1000 ppm in 2100, the average surface ocean pH will decrease from 8.1 to 7.7 during the coming 90 years. Polar (amphoteric) organic contaminants, like antibiotics, change net charge with pH in ways depending on molecular structure. The neutral form is considered most bioavailable and thus most toxic. In future more acidic oceans, polar organic contaminants will reside in forms differently charged than today. The contaminant "toxicity map" may thus have to be redrawn. We investigated the combined effect of reduced sea water pH and antibiotics on natural pelagic bacterial communities collected during spring bloom and winter conditions in the Gullmar fjord, Sweden. Collected seawater with intact pelagic biological communities were exposed to amoxicillin (Amox), ciprofloxacin (Cip) or no antibiotics at pH 8.1 and 7.7 (intermittent CO<sub>2</sub> bubbling). Amox and Cip were chosen due to their frequent use, occurrence in the marine environment, and amphoteric properties acting opposite within the relevant pH span. We predicted Cip to have a stronger bactericidal effect at pH 8.1, since a larger fraction then is neutral compared to at pH 7.7. The opposite was predicted for Amox. Bacterial

abundance was measured using epifluorescence microscopy (DAPI-staining) and bacterial production was quantified with <sup>14</sup>C-leucine incorporation techniques. Bacterial community diversity was identified using DGGE on *rpoB* gene amplicons. Acidification alone consistently reduced bacterial abundances and stimulated production. A clear combined stress effect of pH and antibiotics was observed acting on all measured variables, where the presence of Amox augmented the pH effect while Cip hampered or even reversed it. The less diverse winter bacteria community appeared more sensitive and thus less resilient compared to the more diverse spring bloom community. As predicted, the bactericidal effect of Amox was greater at low pH while the opposite was true for Cip. We conclude that impact assessments of ocean acidification on marine organisms should include effects of pH induced change in polar contaminant bioavailability and toxicity.

## **Soil Ecology and Ecotoxicology: Pillars Supporting the Conservation and Protection of Soil Biodiversity and Ecosystem Services during the International Year of Soils**

Villenave, ELISOL Environnement; G. Pérès, INRA Agrocampus Rennes

Introduction - Despite no European directive exists for soil protection, this key component of ecosystem needs to be protected. To fill the lack of tools to monitor the soil threats and to assess the impact of soil management, biological indicators have been developed in the French program Bioindicators 2 (ADEME). To facilitate the choice of relevant bioindicators by end-user depending on their problematic, the objective was also to develop a web interface. On the 47 plots of 13 sites (agricultural, industrial and forest), the influence of soil characteristics and soil use on the response of 80 biological parameters (fauna, flora and microorganisms) have been assessed by using linear multivariate regressions. Results - The soil texture and the organic carbon rate have been identified as the main soil characteristic influencing the biological responses, even if each bioindicator is influenced by its own pool of soil parameters. It underlines the necessity to use battery of bioindicators for an integrative assessment of soil quality. An influence of soil contaminants (organic or metallic) have been highlighted for 86% of the bioindicators showing the necessity to consider their bioavailability for suitable soil management. A web interface has been implemented (<http://ecobiosoil.univ-rennes1.fr/ADEME-Bioindicateur/>). It presents all the biological methods developed in the program and allows consultation of the variation range of each bioindicator considering site contexts and soil physico-chemical characteristics of soils thus leading to provide a first benchmark. It also provides tools to the end-users to select the bioindicator(s) which best fit(s) with their own site problematic (agricultural practices, bioavailability of contaminants, soil monitoring...) and to communicate (technical sheets...). Conclusion - For the first time, the soil properties influence on the response of 80 bioindicators was characterized under similar environmental conditions. As each bioindicator is influenced by a specific pool of soil parameter, chemical measures cannot be used as a surrogate of biological measures. This program has provided usable tools for a biologically-based site management.

529

#### **Incorporation of a new A horizon 'soil fingerprinting' framework into soil ecotoxicity assessments**

N.C. Feisthauer, C.A. Fox, Agriculture and Agri-Food Canada / SCIENCE AND TECHNOLOGY BRANCH; G. Broll, University of Osnabrueck / Institute of Geography; C. Tarnocai, E. Kenney, D. Kroetsch, Agriculture and Agri-Food Canada / SCIENCE AND TECHNOLOGY BRANCH; M. Joschko, Leibniz Centre for Agricultural Landscape Research / Institute for Landscape Biogeochemistry Soil quality is fundamental to soil biodiversity, function and the provision of services such as food production, and is derived from characteristics of soil biological, chemical and physical components. Each of these components influences the response of soil organisms to contamination and should be considered in the interpretation of ecotoxicity assessments. However it is difficult to describe the constituents of soil physical, chemical and biological components in

a manner that is succinct, repeatable and has the potential to be quantified. A unique "soil fingerprinting" Framework was developed to record and monitor the impacts on soil quality from environmental stressors and land use management. The Framework provides an enhanced soil A horizon descriptor methodology to systematically track and record change in soil chemical, physical and biological characteristics. The enhanced horizon designation generated is analogous to a genetic code or "soil fingerprint" for an individual soil sample at the time the sample was collected. The Framework monitors A horizon characteristics that not only represent dynamic soil properties (e.g., soil structure, organic carbon, etc.) but also soil and land information (e.g., soil texture, land use) providing data to allow comparative interpretations of soil quality changes and identify trends due to human activities (e.g., soil management practices, remediation, etc.) among different soils, or the same soils under different conditions or at different times. The design of the Framework is modular, meaning any level of information can be removed and new levels can be added. For example, levels for soil microbial respiration, root biomass, microarthropod toxicity etc. can be added. The Framework then generates fingerprints that are unique identifiers of the nature and context of the key dynamic soil properties related to soil quality as one integrated descriptive label together with ecotoxicity information. For instance, by including soil structure, the Framework can integrate physical characteristics that significantly influence soil biological endpoints but that are not often included in ecotoxicity assessments. A database of fingerprints, generated either over time or among sites, provides enhanced opportunities to quantitatively analyse multiple lines of evidence in contaminated site assessments.

### 530

**Soil microbial response to toxicants varies with soil moisture and temperature**  
S. Thiele-Bruhn, University of Trier / Soil Science; R. Reichel, Department of Soil Science

In guidelines, it is not regulated or considered that the status of soil biota is not constant but may vary depending on soil moisture and temperature. This might influence the biodiversity of soil organisms as well as their susceptibility towards chemicals. The effect of different soil moisture and soil temperature on the susceptibility of soil microorganisms towards selected toxicants was tested. To this end, soils were either pre-incubated at three different temperatures (10, 20, 30 °C) or (b) at three different soil moisture levels (30, 50, 70% WHCmax). Microbial respiration, microbial biomass C<sub>mic</sub> and N<sub>mic</sub> and dehydrogenase activity were determined as endpoints to investigate dose-related effects of bronopol. In a second study, soil samples were exposed to repeated drying and rewetting cycles in a 49-d fully controlled climate chamber pot experiment with planted soil. Sulfadiazine was added with manure and effects on microbial community structure were determined from PLFA and 16S rRNA gene analysis. Results show that the pre-incubation of the soil samples at different moisture and temperature status altered the diversity of the community. Consequently, this changed the susceptibility of the microbial community towards bronopol. Dose-related effects of bronopol varied between samples of different pre-incubation status. A stronger effect on samples with higher biomass and respiration activity in the control corresponds with the biostatic mode-of-action of the pollutant that requires an active microbial community to exert its effect. Drying-rewetting influenced the microbial community. Significantly lower total PLFA concentrations (p<0.05) were determined in sulfadiazine treated samples when they were additionally exposed to drying-rewetting cycles. Similar results were found by 16S rRNA gene analysis. Significant shifts (p<0.05) in the  $\beta$ -proteobacteria and pseudomonas community structure depended on not only on drying-rewetting but even more on the direction of the soil moisture change. It is concluded that toxicity tests with soils not only require the definition and standardization of test parameters but also of the pre-treatment of the soil samples. Also, it must be expected that effects of pollutants in a field soil may significantly deviate from the results of laboratory tests.

### 531

**Spatial and temporal dependency of ecosystem services on soil processes in invaded grasslands.**

S.D. Siciliano, University of Saskatchewan / Toxicology Group and Department of Soil Science; E. Lamb, Saskatchewan University / Plant Ecology and Biostatistics Dept; M. Brummell, University of Saskatchewan

The protection of soil processes from abiotic and biotic stressors is rationalized on the basis that these processes are linked to critical ecosystem services. Ecosystem services such as climate regulation, pollutant degradation, nutrient cycling, biomass degradation and forage quality are spatially dependent and temporally variable across a landscape. Thus, in order to link soil processes and community structure to ecosystem services, one should incorporate spatial and temporal variability of these services and their corresponding link to the soil community. We investigated the temporal and spatial dependency of ecosystem services and soil community structure across in a rangeland undergoing smooth brome invasion from soil thaw to freeze (26 weeks) in the summer of 2014. Smooth brome invaded soil samples had substantially altered carbon dioxide flux, nutrient cycling and biomass recycling compared to the native plant community. Invaded soil communities had increased C, N and S cycles but had decreased biomass decomposition activity. Other indicators of soil community structure such as dehydrogenase or phosphatase activity were not influenced by invasion and gross physical parameters such as moisture and temperature were also not affected by invasion. In previous work we

demonstrated that there were substantial changes in microbial richness and nitrogen cycling associated with smooth brome invasion. If this trend continues at this site, it appears that these alterations in microbial community structure result in changes in ecosystem services.

### 532

**Wastes or products? Can agricultural application be (part of) the solution for the disposal of organic wastes?**

J. Renaud, Department of Life Sciences; S. Chelinho, IMAR - CMA / Department of Life Sciences; P. Alvarenga, Polytechnic Institute of Beja / Department of Technologies and Applied Sciences; C. Mourinha, Polytechnic Institute of Beja; P. Palma, Instituto Politécnico de Beja / Department of Technologies and Applied Sciences; J.M. Sousa, Faculty of Engineering of University of Porto / Chemical Engineering; T. Natal da Luz, University of Coimbra / Department of Life Sciences  
In recent years the production of organic wastes has increased rapidly and their deposition in landfills constitutes an unsustainable way of waste disposal. Thus alternatives must be found. The use of organic wastes as soil amendments in agriculture could be an important alternative benefiting from their high nutrient and organic matter content and also their positive effects on the aggregation and structural stability of soils. However, this practice should be carefully monitored for the environmental risk posed by many wastes due to the presence of substances with hazardous effects on soil organisms. So, how to properly assess the risks of wastes? With this question in mind, and based on data from reproduction (*Enchytraeus crypticus*, *Hypoaspis aculeifer*, *Eisenia andrei*) and germination tests (*Lactuca sativa* and *Lolium multiflorum*) for 9 different organic wastes, this presentation aims at discussing the challenges and necessary changes to implement in a foreseeable assessment scheme to better unravel the potential risks of organic wastes and their use as soil amendment products. Results obtained demonstrate that organism responses were not consistent and no general sensitivity trend across all wastes could be found. This supports the need for a test battery including several organisms to account for differences in sensitivity and in exposure routes to adequately evaluate environmental impacts. Furthermore, wastes with low contaminant loading in some cases showed higher toxicity than wastes with high levels of contaminants. This suggests that chemical analysis *per se* is not sufficient to assess environmental risks since it may over or under estimate the toxicity of wastes. This also indicates that the list of parameters for analysis should be extended beyond traditional contaminants (e.g., pH and salinity) that, in some cases, may be the ones originating toxicity. Overall the re-use of wastes as soil amendments would benefit the reduction of waste disposal and improve soil quality for agricultural crops reducing the need of inorganic fertilizer application. This strategy could also aid in promoting good practices for waste producers in order to reduce potential hazards and be eligible for agricultural application. This study highlights the need to expand the list of chemical parameters to screen and the need of including ecotoxicological tests as a complement of chemical analysis to evaluate the quality of wastes as soil amendments.

### 533

**Novel endpoints for the Enchytraeid Reproduction Test - hatching, growth, full life cycle - to estimate population dynamics**

R.C. Bicho, Universidade de Aveiro / CESAM Department of Biology; F.C. Santos, Biology CESAM; M. Gonçalves, University of Aveiro, Department of Biology & CESAM / Biology; A.M. Soares, M. Amorim, Universidade de Aveiro / Department of Biology and CESAM

Soil ecotoxicity standard tests for invertebrates are usually limited to the assessment of endpoints like survival and reproduction. Adverse effects may occur at other developmental stages, e.g. embryo development, hatching or growth. The species *Enchytraeus crypticus* is a model organism in the standard soil ecotoxicology test, where survival and reproduction are assessed. In the present study we optimized the method to include additional endpoints. Tests start with synchronized age organisms', a major advantage compared to the standard. The test includes additionally hatching success, growth, maturation status and full life cycle. Moreover, cocoon production and population growth rate were calculated. Cadmium was used as validating test substance. Results indicated that Cd is embryotoxic, main effect occurs on the embryo developmental stage and maturity. Further, the full life cycle test can discriminate between pre- and post-embryo formation and provides life-history information that can be integrated to predict population increase and population growth rate.

**Innovations in environmental analytical chemistry: the quest for pollutants using target and non-target approaches (III)**

### 534

**'Semi-Targeted' Analysis of the River Thames: Combining Targeted and Non-Targeted Approaches for Pharmaceutical and Illicit Drug Residue Detection**

K. Munro, Analytical and Environmental Science; A. Edge, C.P. Martins, Thermo Fisher Scientific; D.A. Cowan, Kings College London / Drug Control Centre; L. Barron, Kings College London / Analytical and Environmental Science  
The potential of suspect/non-targeted analytical approaches using high resolution analytical techniques for pharmaceuticals and related contaminant identification in

the environment has been widely acknowledged in recent years. By developing better post-data acquisition mining tools, a larger number of unknown contaminants can be potentially identified in parallel with a traditional targeted analysis. A more comprehensive understanding of the true breadth of pharmaceutical occurrence in the environment can therefore be gained. Presented herein is the development of a 'semi-targeted' screening method using solid phase extraction (SPE) and liquid chromatography-high resolution mass spectrometry (LC-HRMS) for a temporal and spatial study of drug occurrence in the River Thames. This novel 'semi-targeted' approach combines targeted analysis, through determination of pre-selected analytes, with non-targeted analysis, allowing retrospective identification of unknowns using optimised data-mining screening tools. A broad SPE extraction method was developed using 45 structurally diverse compounds. Detection was performed using HRMS (Exactive), permitting simultaneous quantification of target analytes and qualitative semi-targeted analysis for additional pharmaceutical content. Data-mining software was used to develop and apply an optimised screening method, using matrix-matched reference standards to confirm the presence of unknown contaminants. Grab samples were collected during two week-long river sampling campaigns, at two sites covering a tidal region of the Thames which receives raw untreated wastewater from 7 combined sewer overflow (CSO) vents during times of heavy rainfall. In general, no overall temporal or spatial trends were observed, with any variation remaining on a compound specific basis. An apparent spike in concentration of caffeine was observed, which could be indicative of a CSO event, and will be discussed in combination with rainfall data. The optimised data-mining screening method was used to shortlist > 450 potential contaminants within the river water samples. The presence of 12 shortlisted unknown suspects was confirmed using a matrix-matched standard. Overall, by combining a targeted quantification method with a qualitative non-target approach, the applied semi-targeted method resulted in a more comprehensive analysis of the river, underlying its potential in the analysis of pharmaceuticals in the environment.

### 535

#### **Suspect screening of pharmaceuticals and their metabolites in fish by UPLC-HRMS.**

J. Aceña, IDAEA-CSIC; L. Benjam, University of Girona / Institute of Aquatic Ecology; S. Perez, IDAEA-CSIC / Environmental Chemistry; D. Barcelo, IIQAB-CSIC / Institute for Environmental Assessment and Water Research  
In the last decade, the occurrence of pharmaceuticals in rivers has caused concerns about potential adverse effects on exposed wildlife. Although some studies have been reported the occurrence of pharmaceuticals in different fish tissues, still very little is known about their disposition in fish. In this context, we wanted to evaluate the metabolism of frequently detected drugs in fish performing a rapid screening of bile. To this aim, we performed a preliminary study identifying bile metabolites in fish placed in tanks and treated with two of the most commonly detected pharmaceuticals, carbamazepine and ibuprofen. Once the identification of fish metabolites was accomplished, fish were collected from rivers, their bile isolated and analyzed for the identified metabolites and the corresponding parent drugs. In order to have a broad perspective of the metabolism in freshwater fish of those pharmaceuticals which are found in river waters, a suspect screening of drugs and their predicted metabolites in fish bile and muscle was evaluated by ultra-high performance liquid chromatography - high-resolution mass spectrometry (UPLC-HRMS). The accurate mass measurements obtained by HRMS allowed screening for suspected drugs and their metabolites and provided plausible chemical formulae. The MS/MS spectra of metabolites and the parent compounds allowed to propose plausible structures for metabolites in fish bile. With this approach several phase I and phase II metabolites were identified. The suspect analysis of muscle allowed the detection of more than ten different drugs and demonstrated the uptake of drugs from water and their plausible accumulation. Psycho-active drugs were one of the most commonly detected drugs. Their identities were proposed by matching their accurate MS and MS/MS data against different libraries. Finally, authentic standards were employed to confirm the proposed drug identities and to determine analyte concentrations in the fish samples. Concentrations of pharmaceuticals were determined in the range of ng/g. Thus this approach highlights that UPLC-HRMS is a powerful tool for simultaneous quantitative and qualitative analysis, allowing the search for suspected metabolites, their identification and the quantitation of target compounds. Furthermore, UPLC-HRMS provides a great deal of information about each sample, allowing the retrospective analysis.

#### **Detection and identification of new psychoactive substances in pooled urine using High Resolution All-Ions MS/MS**

J. Kinyua, University of Antwerp / Pharmaceutical Sciences; N. Negreira, University of Antwerp / Faculty of Pharmaceutical Sciences; A.A. Van Nuijs, University of Antwerp; M. Ibanez, DELTARES / Marine and Coastal Systems; L. Bijlsma; B. Miserez, University of London; F. Hernandez, Universitat Jaume I; A. Covaci, University of Antwerp, Toxicological Center / Toxicological Centre  
New Psychoactive Substances (NPS) are compounds that mimic effects of illicit drugs like cocaine, cannabis and amphetamines— and are synthesized to evade law enforcement by introducing slight modifications to chemical structures of controlled substances. Currently, there are around 350 NPS in the market, most of

which have no commercially available reference standards making it challenging to develop targeted methods for their analysis. In addition, their use is very sporadic depending on popularity amongst users. High-resolution mass spectrometry (HRMS) using quadrupole time-of-flight (QTOF) analyzer is a useful technique for wide-scope screening since it provides sensitive, full-spectrum MS data with high mass resolution and accuracy. All Ions MS/MS (also known as MSE) is a technique that is available for liquid chromatography (LC) - HR-QTOFMS instruments. In this work, a screening HRMS All-Ions based workflow for data acquisition and data processing using a combination of sophisticated techniques and key parameters is used to facilitate identification of NPS. This rapid cost-effective workflow utilizes a data mining algorithm that is linked to an in-house database containing >1500 compounds (NPS and their metabolites) and considers various factors including peak abundance, symmetry, isotopic pattern of precursor ions, and retention time. Also, the technique correlates detected compounds to product ions in MS/MS spectra produced resulting in confident compound identifications. The workflow was successfully applied to the analysis of 13 pooled urine samples collected in London. On average, 2% of the detected peaks were assigned to target NPS, with about 20 NPS reference standards available. The remaining peaks were grouped into false positives (70%) and tentative identifications (28%) for which product ions were correlated to identify the compounds after fragment elucidation. This strategy is a useful tool in target and suspect screening with the advantage of using these data in the future, in a retrospective analysis searching for additional compounds without the need of re-injecting the sample extracts.

### 537

#### **UHPLC-HRMS characterisation and toxicity assessment of ofloxacin transformation products after TiO<sub>2</sub> nanoparticles and TiO<sub>2</sub> nanofibers photocatalysis**

J.J. Villarin, Analytical Chemistry; L. Meschede Anglada, A. Serra Clusellas, A. Conesa Cabeza, Leitat Technological Center; E. Moyano Morcillo, University of Barcelona

1. Introduction There is an increasing concern over antibiotics and its presence in the environment, since they and/or their metabolites could induce bacterial resistance. Amongst antibiotics, fluoroquinolones are a class of antibacterial agents widely used for human and veterinary applications and conventional sewage treatment plants are not able to efficiently remove these chemicals. In this study, the degradation of the fluoroquinolone ofloxacin (OFX) was under investigation using heterogeneous photocatalysis based on TiO<sub>2</sub> nanoparticles (NPs) and nanofibers (NFs). Effect directed analysis (EDA) was used to study the potential toxicological activity of the generated transformation products (TPs) during the photocatalytic process. 2. Materials and methods Photocatalytic experiments with suspended and supported TiO<sub>2</sub> NPs or NFs were performed in a borosilicate photochemical reactor irradiated with artificial UVA light containing an OFX solution (10 mg L<sup>-1</sup>). Samples were analysed on an Accela UHPLC system coupled to a Q-Exactive Orbitrap. Eight HPLC fractions were collected and bio-tested using *vibrio fischeri* and HepG2 and HK2 human cell lines. *In silico* predictions were performed with the OECD Q(SAR) Toolbox v3.2 and T.E.S.T software. 3. Results and discussions Suspended TiO<sub>2</sub> NPs achieved complete OFX removal faster than TiO<sub>2</sub> NFs. No significant differences were observed between TiO<sub>2</sub> NPs and TiO<sub>2</sub> NFs under supported conditions, achieving complete removal in 240 minutes. Having identified 60 OFX TPs, six main routes were established to be promoting its degradation. Some of these TPs were found to be persistent, as no complete removal was achieved. *In-vitro* studies revealed that aliquotes collected at 15 and 20 minutes of the process showed toxic effects. The IC50 values (expressed as the dilution percentage of the sample) were of 11.6 and 22.7% respectively, while OFX did not show toxicity. At the mentioned times the OFX concentration was 6.1 and 5.8 mg L<sup>-1</sup> respectively. These results clearly show that generated TPs are more toxic than OFX. In order to identify which TPs were responsible for the observed toxic effect, both collected samples were fractionated by HPLC, analysed by UHPLC-HRMS and bio-tested with the mentioned techniques. *In-silico* tests were showed that the identified TPs are presumably more toxic than the parent compound. However, the synergy effect of all the present molecules was not possible to take into account with these simulations.

#### **Comprehensive two-dimensional liquid chromatography coupled to time of flight mass spectrometry for effect-directed analysis of wastewater treatment plant effluent in the Netherlands**

X. Ouyang, Institute for Environmental Studies IVM; J. Legradi, Institute for Environmental Studies; P. Leonards, VU University, Institute for Environmental Studies / Institute for Environmental Studies IVM; J. de Boer, VU University / IVM; R. Van der Oost, Waternet; J. Legler, VU University / Institute for Environmental Studies; M. Lamoree, VU University, Institute for Environmental Studies / Institute for Environmental Studies

Due to massive human activities such as agriculture, wastewater discharges and industrial manufacturing, potentially harmful chemicals reach the environment. These chemicals are large in number and possess diverse physicochemical properties, ranging from non- or weakly polar compounds such as polycyclic aromatic hydrocarbons (PAHs), polychlorinated biphenyls (PCBs) and polybrominated diphenyl ethers (PBDEs) to strongly polar compounds such as novel pesticides, pharmaceuticals and personal care products

(PPCPs). Comprehensive two-dimensional liquid chromatography (LC×LC) is an emerging technique that has been applied in areas of notable sample complexity, due to its greater peak capacity and tunable selectivity by different stationary phase combinations. In our study (EDA-EMERGE project, EU contract 290100), for the first time a LC×LC system linked to a 96-384 well fraction collector, a UV detector and a high resolution time of flight mass spectrometer (ToF-MS) was developed to support the identification of emerging toxicants in Effect-Directed Analysis (EDA). The effluent sample (project sponsored by the BE-Basic Foundation) were fractionated into 4×96 well plates and the collected fractions were tested for developmental toxicity using a high throughput zebrafish embryo toxicity (ZFET) assay and also an acetylcholinesterase (AChE) assay. The performance of an LC×LC system was explored with regard to its potential for the analysis of standard mixtures of environmental contaminants and wastewater effluent extracts. We have demonstrated that a significant enhancement of the peak capacity facilitates the rapid identification of toxic compounds by online LC×LC-ToF MS and high throughput toxicity testing, leading to a comprehensive chemical characterization of environmental water samples, including toxicological evaluation of the identified compounds.

#### Linking Influent and Effluent Peaks from Biological Wastewater Treatment to Detect Relevant Nontarget Compounds

J. Schollee, Eawag, Swiss Federal Institute of Aquatic Science and Technology / Environmental Chemistry; E. Schymanski, Eawag Swiss Federal Institute of Aquatic Science; S. Avak, Eawag Swiss Federal Institute of Aquatic Science and Technology; J. Hollender, Eawag / Environmental Chemistry  
Transformation products (TPs) are formed during the wastewater treatment process (WWTP) and lab studies and targeted screening can only provide a limited picture of the compounds present. This project focuses on using nontarget screening with liquid chromatography coupled to high-resolution mass spectrometry (LC-HRMS) and tandem MS (MS/MS) and aims to identify new organic micropollutants. With a combination of LC-HRMS, MS/MS, and multivariate analysis, prioritization of the nontarget peaks was done to select compounds interesting for structure elucidation. Samples were enriched with solid-phase extraction and were analyzed with LC-HRMS using electrospray ionization in positive and negative mode. Pre-processing was carried out with the software R, including peak picking, isotope/adduct clustering, and feature building. Principal component analysis (PCA) was used to classify peaks based on where they are most often detected (i.e., in the influent or effluent samples). Links between the two groups were explored based on known biotransformation reactions. When matches were found, prioritization was done using peak shape and intensity, significance of the intensity difference between the two sample types, and similarity of the MS/MS spectra. From the PCA, 9758 features were classified as potential parents and 3011 features as potential TPs. Using 7 biotransformation reactions, 4249 potential links were found. From this, 156 were selected for targeted MS/MS based on the workflow prioritization. MS/MS fragmentation from the proposed parent and TP were compared, and 19 links with an MS/MS similarity score of higher than 0.5 were chosen for further structure elucidation. In one example, the MS/MS fragmentation of the parent and TP were similar; both contain fragments at masses 103.0390 and 89.0597. Other linkages were also found with these fragments. The mass difference between the two parent compounds was 44.0264 mDa [C<sub>2</sub>H<sub>4</sub>O]. As homologue series such as this have been reported previously in WW, this series was extrapolated to higher and lower masses and the EICs visualized. After the treatment some of the lower masses were removed, although some of the higher mass homologues appear unchanged or increased after the treatment. Preliminary results indicate that by applying multivariate analysis and a nontargeted workflow, relevant compounds can be found using these methods, not only between parent and TP but also potentially new homologue series.

### Recent scientific developments in bioaccumulation research and assessment

540

#### Bioaccumulation Assessment: Developing Frameworks and Finding Common Ground

J.A. Arnot, ARC Arnot Research & Consulting / Department of Physical Environmental Science; J.W. Nichols, U.S. EPA / ORD NHEERL Mid Continent Ecology Division; M. MacLeod, ITM - Stockholm University / Dept of Environmental Science and Analytical Chemistry ACES; E. Papa, Department of Theoretical and Applied Sciences; K. Borga, Department of Biosciences, University of Oslo / Department of Biosciences; H. Laue, Givaudan Schweiz AG / Fragrances S T; P. Leonards, VU University, Institute for Environmental Studies / Institute for Environmental Studies IVM; F.A. Gobas, Simon Fraser University / School of Resource and Environmental Management Faculty of Environment  
Bioaccumulation is the net result of competing rates of chemical uptake and elimination in an organism. Various methods, metrics and criteria have been developed and proposed for bioaccumulation (B) assessment. The octanol-water partition coefficient ( $K_{ow}$ ) and the bioconcentration factor (BCF) are B metrics currently implemented in regulatory programs. Alternative metrics for B assessment have been proposed including the biomagnification factor (BMF), the

trophic magnification factor (TMF), the bioaccumulation factor (BAF), and the total elimination half-life ( $HL_T$ ). Mass balance models and quantitative structure-activity relationships (QSARs) are often useful, particularly for screening-level assessments. A Bioaccumulation Workshop organised and sponsored by the European Chemical Industry Council-Long Range Research Initiative (Cefic-LRI) was hosted at the European Chemicals Agency (ECHA) in Helsinki, Finland. This presentation summarizes some discussion points and proposes a path forward for improving bioaccumulation science and assessment. All data (measured or predicted) need to be critically evaluated and carefully interpreted for relevance and reliability. Mass balance (process) models provide a framework to incorporate and compare various sources of bioaccumulation information (in vitro, in vivo, in silico, in situ) for a range of bioaccumulation assessment endpoints of interest. The framework can be used to determine if there is consistency or divergence in theoretical and empirical knowledge, thus providing confidence in B assessment. Definitive B evaluations should be based on a weight-of-evidence approach. A common thread for B assessment and a key model input parameter for the reliable prediction of BCF, BMF, BAF, TMF and  $HL_T$  endpoints for hydrophobic chemicals in fish and other species is the primary biotransformation rate constant  $k_B$  (or  $HL_B$ ). In vitro, in vivo and in silico methods for estimating  $k_B$  have been developed and evaluated. Confidence in  $k_B$  can be obtained by corroborating in vitro, in vivo and in silico estimates and the applicability domains of current  $HL_B$ -QSARs can be expanded through strategic chemical selection and testing. Research programs to obtain better quantitative (rate) and qualitative (metabolite) information for chemical biotransformation in a range of species are recommended. The workshop also highlighted the need for guidance documents on some of the new developments for B criteria.

541

#### Decamethyltetrasiloxane (L4): Assessment of biomagnification and toxicity through aquatic/dietary lab studies, fugacity ratios, and field data

K.B. Woodburn, Dow Corning Corporation / HES; D.E. Powell, R.M. Seston, J. Kim, Dow Corning Corporation / Health and Environmental Sciences; J.A. Durham, Dow Corning Corp. / Health and Environmental Sciences  
Lipophilic chemicals, such as the cyclic and linear methylsiloxanes, are considered possible candidates for potential bioaccumulation ('B') in aquatic food webs, and are often found in sediments when present in aquatic ecosystems. As such, risk assessments may be focused on protection of benthic organisms, and probabilistic risk assessment (PRA) methods allow the risk assessor to include stochastic properties of both exposure and response (i.e., toxicity). The objective of this work was to examine laboratory and field data concerning the bioaccumulation and ecotoxicity of decamethyltetrasiloxane (L4), a linear methylsiloxane. Laboratory bioconcentration studies have been performed to determine the BCF value for L4 with the guppy (*Poecilia reticulata*) and the fathead minnow (*Pimephales promelas*), and the BCF values range from 10 to 3850 L/kg-ww, and the latter study reported an depuration half-life of approximately seven days. Laboratory BMF values for L4 range from an empirical BMF of 0.04 with goldfish (*Carassius auratus*) to a kinetic BMF<sub>k</sub> of 3.5 with rainbow trout (*Oncorhynchus mykiss*). The latter study excluded trout liver tissue from chemical analysis and the depuration rate constant ( $k_2$ ) was 35-fold lower than measured in the kinetic BCF study, likely due to the exclusion of L4 metabolite products from analysis. Experimental BCF and BMF values were used to predict a TMF value using a trophic level-modified AQUAWEB model, and all B metrics are presented as a series of dimensionless fugacity ratio values. Finally, chronic benthic toxicity no-observed effect concentrations (NOECs) for L4 are compared to field observed sediment concentrations using a PRA approach. The PRA revealed an absence of overlap of L4 sediment concentrations (generally non-detectable at

542

#### Why existing risk assessment tools may get it wrong for hydrophobic organic contaminants: impact of benthic invertebrate biotransformation for P and B

H. Selck, Roskilde University / Dept Environmental Social and Spatial Change  
Current risk assessment of hydrophobic organic contaminants is based on these contaminants potential to persist (P) in the environment, bioaccumulate (B) in biota and their potential toxicity (T). This presentation addresses the importance of environmental and physiological factors for affecting bioaccumulation, including biotransformation, of sediment-associated hydrophobic organic contaminants in the aquatic environment and thus the importance of these factors for contaminant persistence. Special emphasis is placed on the 1) impact of benthic invertebrates on fate of sediment-associated contaminants, and 2) variability of biotransformation capacity among benthic invertebrates. In conclusion, even though biotransformation capacity varies widely among benthic invertebrates, it is evident that biotransformation may reduce body burden and facilitate the removal of sediment-associated organic contaminants, and especially so in polychaete species thriving in organically enriched and contaminated sediment. Existing risk assessment tools and methods may therefore not be designed to fully address hydrophobic organic contaminants, and evidence point to including benthic invertebrate biotransformation in P and B assessment. By focusing future research on physiological properties that impact accumulation and biotransformation of B and P substances we will be able to reduce uncertainty and thus improve our ability to estimate the first step in B, namely transfer from the abiotic (sediment) to the lower trophic level (i.e., the first step in the benthic-pelagic food web).

### Investigating differences in root to shoot transfer and xylem sap solubility of organic compounds between zucchini, squash and soybean using a pressure chamber method

W.J. Doucette, Utah State University / Utah Water Research Laboratory; N. Garvin, Aqua Engineering

A pressure chamber method was used to examine differences in the root to shoot transfer and xylem sap solubility of caffeine (log Kow = -0.07), triclocarban (log Kow = 3.5-4.2) and endosulfan (log Kow = 3.8-4.8) for zucchini (*cucurbita pepo* ssp *pepo*), squash (*cucurbita pepo* ssp *ovifera*), and soybean (*glycine max* L.). Transpiration stream concentration factors (TSCF) for caffeine (TSCF = 0.8) were statistically equivalent for all plant species. However, for the more hydrophobic endosulfan and triclocarban, the TSCF values for zucchini (TSCF = 0.6 and 0.4, respectively) were 3 and 10 times greater than the soybean and squash (TSCF = 0.2 and 0.05, respectively). The difference in TSCF values was examined by comparing the measured solubilities of caffeine, endosulfan and triclocarban in deionized water to those in soybean and zucchini xylem saps using a modified shake flask method. The measured solubility of organic contaminants in xylem sap has not previously been reported. Caffeine solubilities in the xylem saps of soybean and zucchini were statistically equal to deionized water (21500 mg/L) while endosulfan and triclocarban solubilities in the zucchini xylem sap were significantly greater (0.43 and 0.21 mg/L, respectively) than that of the soybean xylem sap (0.31 and 0.11 mg/L, respectively) and deionized water (0.34 and 0.11 mg/L, respectively). This suggests that the enhanced root to shoot transfer of hydrophobic organics reported for zucchini is partly due to increased solubility in the xylem sap. Further xylem sap characterization is needed to determine the mechanism of solubility enhancement.

### Passive dosing to characterize the sorptive capacities of biota lipids from various trophic levels

A. Jahnke, Stockholm University / Department of Cell Toxicology; A.H. Kierkegaard, Stockholm University / Department of Environmental Science and Analytical Chemistry ACES; P. Mayer, Technical University of Denmark / Department of Environmental Engineering; J. Holmbäck, R.A. Andersson, Stockholm University / Department of Analytical Chemistry; M. MacLeod, ITM - Stockholm University / Dept of Environmental Science and Analytical Chemistry ACES

In a bioaccumulation context, lipids often are the major partitioning phase for hydrophobic organic chemicals. What is referred to as "lipid", however, is a complex matrix consisting of a highly variable mixture of neutral ('storage') and polar ('membrane') lipids. Furthermore, depending on the organism's fraction of lipids and proteins and the properties of a chemical, other sorptive phases (e.g. proteins) may be particularly important. The aim of the present study was to expand our previous studies of the sorptive capacities of pure lipids into more realistic media, i.e. extractable organic matter (EOM) obtained by solvent-based extraction of biota from various trophic levels. The following steps were part of the experiment: i) solvent-based extraction of tissue homogenates of five different species: whole blue mussels, herring muscle, pork bacon, guillemot egg and seal blubber; ii) passive dosing of replicates of each EOM sample with the cyclic volatile methyl siloxanes (cVMS) D4, D5, D6, and tri- and tetrachlorobenzene (TriCB and TeCB) via a common headspace for 28-214 hours; iii) sampling of EOM and olive oil controls at different time points; iv) purge and trap extraction of the model chemicals onto ENV+ SPE cartridges, elution and GC/MS analysis; v) determination of the fractions of storage and membrane lipids in all samples via NMR, SPE followed by LC-ELSD, and GC-FID. The fraction of EOM extracted from the five biota samples ranged from 1.4% (whole blue mussels) to 95% (seal blubber). The equilibration between the olive oil donor and the EOM samples and olive oil controls in the passive dosing units was fast (in the range of days) for the cVMS. The chlorobenzenes approached, but did not fully reach equilibrium during the experiment. The obtained results showed minor differences of less than a factor of 3 in the sorptive capacities of the EOM obtained from biota of different trophic levels. The olive oil controls generally had higher sorptive capacities for the model chemicals than the EOM samples. The partitioning of the model chemicals between EOM and olive oil was not statistically different for EOM originating from bacon and seal blubber, whereas small but statistically significant differences were found for some chemicals in EOM from blue mussels, herring and guillemot egg compared to olive oil. The highest fractions of polar lipids were found in EOM obtained from blue mussels and guillemot egg, which may partly explain the observed differences.

### Exploring the Influence of Molecular Structure on the Membrane Affinity of Organic Bases

s.T. droge, Utrecht University / IRAS; N. Timmer, J.L. Hermens, Utrecht University / Institute for Risk Assessment Sciences

Immobilized Artificial Membrane (IAM) chromatography column was used to determine the phospholipid binding affinity for >100 cationic structures, including primary, secondary, tertiary amines and quaternary ammonium compounds. Eluent conditions were optimized to avoid unwanted electrostatic interactions of the silica

core of the column particles, resulting in intrinsic Klipw measurements for the cationic species. For several weak bases, IAM measurements performed at pH 3.0, 5.0 and 7.4 allowed for determination of the Klipw for both cationic and neutral species. From these experiments, various correction factors between neutral amine and protonated amine species could be established. New experimental Klipw measurements with solid supported bilayer membranes (TRANSIL) for 30 overlapping cations, and literature comparisons of liposomal partitioning Klipw data for ~5 overlapping cations, indicate that the IAM column is a representative high-throughput method. A first elucidation of how the molecular structure influences the membrane affinity of organic cations is made using ~30 basic amine structures that lack polar functional groups besides a single phenyl ring and the charged nitrogen moiety. The anisotropic structuring of an ordered phospholipid layer appears to be crucial in determining the membrane affinity of cations, regarding the strong differences between linear and branched isomeric structures of the same molecular volume. Using a molecular dynamic simulation of a 3D dissolved membrane bilayer structure, we used COSMOthermX/COSMOmic software calculations that combine quantum-chemical calculations with thermodynamics to visualize the ideal positioning of these basic amine structures in a membrane and compared the predicted Klipw values with IAM experimental data. A second series of amines with various functional groups were compared with the simple amine structures to examine if specific fragment values for each individual functional group can be derived. Additionally, COSMOthermX/COSMOmic calculations for these more complex structures were compared with measured IAM Klipw values.

### Developing end-points and effect-based methodologies for characterization of emerging pollutants at relevant exposure concentrations

### Ligand Binding Domain of Estrogen Receptor alpha to generate a bioassay for fast detection of Endocrine Disruptor Chemicals

V. Ferrero, LGC; R. Negrao Carvalho, Institute for Environment and Sustainability / Institute for Environment and Sustainability IES; L. Varani, Research Institute in Biomedicine; L. Calzolari, European Commission, Joint Research Centre / Institute for Health and Consumer Protection; t. lettieri, European Commission - Joint Research Centre / Institute for Environment and Sustainability

Endocrine Disruptor chemicals (EDCs) are compounds capable to bind to estrogen receptor (ER). They exert their toxicity to animals and humans by interfering with the normal function of ER, leading to many adverse effects such as reproduction, hormonal and immune system malfunctions, carcinogenesis and feminization in some fish and amphibians. EDCs are commonly released in the environment as results of anthropogenic activities. Their detection and monitoring are still a challenge since the analytical method cannot measure all EDCs at the concentrations usually found in the environment. Analytical measurements are also unable to predict the combined effect of all EDCs present in an environmental mixture. We developed an assay based on recombinant ligand binding domain of human estrogen receptor  $\alpha$  for fast detection of EDCs as first screening. If a chemical binds to the receptor, it means that it can potentially interfere with the hormone signaling pathways and thus be toxic. Furthermore a rational modification of the ligand binding domain has been designed to generate a mutant receptor to increase the affinity, and therefore the sensitivity towards different classes of compounds (Ferrero VEV et al., 2014). The Ligand Binding Domain (LBD) of the Estrogen Receptor  $\alpha$  is highly conserved among human and aquatic species (fish and amphibians) and it is sufficient to bind estradiol and estrogen-like molecules. The encoding gene of the LBD was expressed in *E.coli* and purified. To test the ability to bind estradiol and other chemicals, an assay was set up using the PolarScreen assay (Life Technologies). We tested the natural ligand 17- $\beta$  estradiol, its close analog 17 $\alpha$ -ethynylestradiol (chosen since it is an emerging pollutant); tamoxifen, an antagonist and three other compounds with known estrogen disrupting activity and significant presence in the environment, bisphenol-A, 4-nonylphenol and 4-tert-octylphenol. An artificial chemical mixture was also tested and compared with other ER based assays (Carvalho RN et al., 2014). The Ligand Binding Domain of the Estrogen Receptor assay (LER) has been conceived for the detection of chemicals which binding to the ER could mean a potential interference with the normal activity of the receptor in the organisms. The assay is fast and easily handled and it can be used as first screening to measure the EDCs in matrices e.g. water, soil and food.

### Assessing the cytotoxic, estrogenic and mutagenic effects of pharmaceutical residues and their photo-transformation products in water

M.I. Vasquez, University of Cyprus / Department of Civil and Environmental Engineering University of Cyprus; M. Tarapoulouzi, NIREASIWRC / Department of Civil and Environmental Engineering University of Cyprus; N. Lambrianides, The Cyprus Institute of Neurology and Genetics; K. Felekis, University of Nicosia / Department of Life and Health Sciences; C. Sticht, M. Saile, N. Gretz, Heidelberg University / Medical Research Center Faculty for Clinical Medicine Mannheim; D. Fatta-Kassinos, University of Cyprus / Nireas International Water Research Center

Pharmaceuticals are now considered as environmental contaminants. Their presence has been reported in the aquatic and the terrestrial environment, as parent compounds, metabolites and/or transformation products. The adverse effects to biological systems caused by the exposure to these compounds are yet to be thoroughly investigated and fully understood. To this end, the purpose of the present study was the assessment of the cytotoxicity, estrogenicity and mutagenicity of eleven pharmaceuticals namely azithromycin, erythromycin, ofloxacin, sulfamethoxazole, trimethoprim, carbamazepine, diclofenac, ibuprofen, atenolol, metoprolol and propranolol. A selection of photolabile active pharmaceutical ingredients was performed to further assess the effects of transformation products that may occur in the environment. Diclofenac, ofloxacin and sulfamethoxazole were photolytically treated in order to investigate the cytotoxicity, estrogenicity and mutagenicity of the mixture of their transformation products on mammalian and human cells. A screening of the gene expression profile was carried out as a supplementary endpoint in order to reveal the mode of action of these transformation products to the human genome. The main findings indicate that mutagenicity was not observed at concentrations lower than 50 mg/L. Interestingly, synergistic effects were observed at an exposure concentration of 10 mg/L to the mixture of pharmaceuticals. No significant estrogenic effects were observed to any of the pharmaceuticals and the mixtures assessed. The gene expression profile was affected to a greater extent by the mixture of diclofenac, ofloxacin and sulfamethoxazole. 644 genes were differentially expressed in the cells treated with the pharmaceutical mixture and 216 were expressed in the cells treated with the irradiated pharmaceutical mixture. 466 genes were expressed in both types of exposure. The most important pathways influenced were the MAPK signalling, the cell cycle, the p53 signalling and the protein processing in endoplasmic reticulum. The proposed approach provides an alternative testing system that sheds light to less studied aspects related to the exposure to pharmaceuticals. Mutagenicity, estrogenicity, cytotoxicity and gene expression profiling could potentially be used in future studies for the assessment of effects in real matrices.

#### Identifying drivers of chemical mixture's bioactivity at realistic environmental concentrations?

I. Rodea-Palomares, Universidad Autónoma de Madrid / Biology; R. Muñoz-Carpena, University of Florida / Department of Hydrology / Water Quality Agricultural / Biological Engineering Faculty; S. Gonzalo, Universidad de Alcalá; M. González-Pleiter, Universidad Autónoma de Madrid; R. Rosal, Ingeniería Química; F. Fernández-Piñas, Universidad Autónoma de Madrid / Biology

Current methodologies applied to characterize the effect of suspect substances, such as emerging micropollutants (EMPs) are based on the classical *dose-response* approach [1]. However, present efforts on the identification and prioritization of new emerging pollutants are hampered by some practical difficulties when trying to apply the *dose-effect* paradigm: In the best cases, clear monotonic *dose-response* profiles are found only at high doses (orders of magnitude higher than relevant ones for realistic exposures). However, very common situations are also the inexistence of monotonicity, non-concentration dependent statistically significant effects at low doses, statistically significant interactions between individually non-active substances, and/or biotic and abiotic factors. All these findings suggest the need to explore new approaches to study the effects of EMPs under more realistic conditions (complex mixtures, low doses, and variable environmental conditions). In the present work we applied a new experimental framework for the effect-based identification of hazardous EMPs. The methodology which we denoted as *GSUA-EDS*, consists in incorporating Global Sensitivity and Uncertainty Analysis (GSUA) tools to assist *Effect-Directed Screening* (EDS) of suspect substances in ecotoxicological studies. GSUA tools are *top-down* approaches which serve to identify important factors driving a system's response independently of any mechanistic assumption, such as linearity, additivity or mode of action (MoA). In the present study, we used the global sensitivity computational screening tool known as Morris Method [2] to study main drivers controlling *low-dose* responses of an *in-vitro* ecotoxicological test when exposed to realistic mixtures of 16 pharmaceuticals. The effect of one environmental stressor (light intensity) was also included in the analysis as an example of the open possibilities that *GSUA-EDS* offers to experimental ecotoxicologists. 1 Altenburger R, Backhaus T, Boedeker W, Faust M, Scholze M (2013) Simplifying complexity: Mixture toxicity assessment in the last 20 years. #### Effects of antifouling biocides to non-target freshwater organisms of three trophic levels

I.B. de Carvalho Benta Santos Oliveira, University of Aveiro & CESAM / Biology department; K.J. Groh, Eawag / UTOX Environmental Toxicology; R. Schonenberger, Eawag / Environmental Toxicology; C. Barroso, University of Aveiro / Biology Department CESAM; K. Thomas, NIVA / Product Metabolism; M.J. Suter, Eawag - Swiss federal Institute of Aquatic Science and Technology / Environmental Toxicology

Biocides are frequently added to antifouling (AF) paints to boost their efficacy in

preventing problems related to biofouling that may lead to i) the deterioration of diverse aquatic equipment and submerged structures ii) the raising of fuel consumption by boats due to the increase of frictional drag and iii) the dissemination of invasive species. The goal is that emerging biocides should maintain a good AF performance and, at the same time, undergo a rapid transformation to less toxic products once released into the water. Thus, they should have low toxicity towards non-target organisms and a minor impact on the environment. The Biocidal Product Regulation (BPR, Regulation EU No. 528/2012) is also demanding a higher protection level for humans and for the environment in order to approve the use of a certain substance. The current work aimed to assess the toxicity of tralopyril, triphenylborane pyridine (TPBT) and capsaicin towards freshwater non-target organisms from three trophic levels: i) the algae *Chlamydomonas reinhardtii* ii) the crustacean *Daphnia magna* and iii) the fish, *Danio rerio*. From the three tested biocides, only tralopyril had an inhibitory effect on *C. reinhardtii* growth, effective quantum yield and ATP content at a concentration of 100 µg/L. Both tralopyril and TPBP were toxic to *D. magna* although TPBP presented a slightly lower 48h - LC<sub>50</sub> of 10µg/L against a 48h - LC<sub>50</sub> of 27 µg/L for tralopyril. In the zebrafish embryo toxicity test (zFET), tralopyril was the most toxic with a 120h - LC<sub>50</sub> of 5 µg/L. For TPBP the 120h - LC<sub>50</sub> obtained was 447.5 µg/L. The occurrence of sub-lethal effects such as heart edema, non-inflation of swim bladder, malformation of the tail and axis, reduced blood flow and changes of the heart rate were also assessed. Capsaicin did not cause lethal effects in any of the three species up to 1mg/L. As it showed the highest toxicity, tralopyril was selected for further studies in zebrafish. Besides the assessment of morphological endpoints following different exposure periods, our study also aims to analyze proteome alterations in exposed zebrafish embryos using mass spectrometry-based Multidimensional Protein Identification Technology (MudPIT) in order to investigate molecular mechanisms of tralopyril toxicity and find novel biomarkers of exposure. Furthermore, a LC-MS/MS method was developed allowing measurement of tralopyril concentrations in the exposure medium.

#### Identifying chemicals that are planetary boundary threats

M.S. McLachlan, Stockholm University / Department of Environmental Science and Analytical Chemistry ACES; M. MacLeod, ITM - Stockholm University / Dept of Environmental Science and Analytical Chemistry ACES; M. Breitholtz, Inst för tillämpad miljövetenskap / Department of Applied Environmental Science ITM; I.T. Cousins, Stockholm University / Department of Environmental Science and Analytical Chemistry ACES; C.A. de Wit, Stockholm University / Applied Environmental Science ITM; L.M. Persson, Stockholm Environment Institute; C. Ruden, Stockholm University / Department of Environmental Science and Analytical Chemistry ACES

**Chemicals can disrupt vital earth system processes to such an extent that the state of the planet is dramatically altered. Stratospheric ozone depletion by chlorofluorohydrocarbons is an example of such a chemical induced disruption. We must manage the planet such that vital earth system processes are not seriously disrupted. The term planetary boundaries has been coined to delimit the safe operating space that we have on the planet. Among the planetary boundaries defined to date are stratospheric ozone depletion, climate change, ocean acidification and phosphorus use. It is likely that there are other – unknown – chemical planetary boundaries, where chemical pollution could potentially disrupt a vital earth system process. If a chemical should do this on a global scale and if the impact would not be readily reversible, the consequences for the planet could be disastrous. We call such chemicals chemical pollution planetary boundary threats. Society has a responsibility to ensure that such chemicals are not released to the environment in sufficient quantities to disrupt vital earth system processes. However, identifying chemical pollution planetary boundary threats is difficult because their adverse impact on vital earth system processes is per definition unknown. In this work we explore how one could identify such chemicals. We begin by defining three conditions that must be fulfilled for a chemical to be a planetary boundary threat. We then define chemical pollution scenarios that could lead to each of the conditions being fulfilled. Finally, for each scenario we define chemical profiles consisting of chemical properties and use patterns. We conclude that prioritizing chemicals in commerce against some of the chemical profiles appears achievable, while for other chemical profiles research is required to make them operational.**

#### Rational design of chemicals and pharmaceuticals and other input prevention measures towards sustainable technological development

#### Advanced QSAR models for use in toxicokinetic modelling

D.A. Sarigiannis, Aristotle University of Thessaloniki / Chemical Engineering; K. Papadaki, AUTH / Chemical Engineering; S. Karakitsios, Aristotle University of Thessaloniki / Chemical Engineering

A current limitation to further introducing PBBK models in the risk assessment arena is the lack of generic character of these models. A critical limiting factor is the

proper parameterization for “data poor” compounds. In order to expand the applicability of PBBK models to cover as much as possible the chemical space, model parameterization for data poor chemicals is done using advanced quantitative structure-activity relationships (QSARs). Several QSAR modeling approaches have been investigated, including (a) an algorithm based on fractional content of and the lipophilicity of the compound of interest; (b) the molecular fractions algorithm that takes into account the frequency of occurrence of the several molecular fragments of the compounds and (c) Abraham’s solvation equation for estimating biological properties, which takes into account the excess molar refraction, the compound dipolarity/polarizability, the solute effective or summation hydrogen-bond acidity, the solute effective or summation hydrogen-bond basicity and the McGowan characteristic volume. Up to now, these QSARs seem to perform adequately for a limited number of chemical families. A major breakthrough came from the use of Artificial Neural Networks coupled to Abraham’s solvation equation for predicting chemical-specific biological/biochemical properties such as blood-tissue partition coefficients, maximal velocity ( $V_{\max}$ ) and the Michaelis - Menten constant. This was a remarkable advance, since the prediction capability of the Michaelis - Menten constant in the existing studies to date was rather poor ( $R^2$  0.3). With our coupled ANN - Abraham’s solvation equation method for the investigated group of 55 chemicals,  $R^2$  rose to 0.8. For the rest of the parameters (partition coefficients,  $V_{\max}$ ), performance of prediction against experimental values was consistently high ( $R^2$  always above 0.9), outperforming any other existing methodology. Overall, the proposed methodology, offers two major advantages: - It helps filling the data gaps of “data poor” chemicals, allowing the use of internal dosimetry metric for a wide array of chemical classes. - It effectively supports the “safe by design” concept for industrial chemicals, by allowing the successful prediction of toxicokinetic behavior based on molecular parameters, thus avoiding chemical structures resulting in bioaccumulative and non-rapidly metabolized chemicals.

## 552

### Computer Aided Discovery and REdesign of Skin Sensitizers - a rational modeling approach of the skin sensitization AOP that provides guidance to molecular redesign of sensitizing chemicals

J. Kostal, Toxfix LLC; A. Voutchkova-Kostal, George Washington University / Chemistry Department

Designing molecules from first principles to have predictable biological activity is still viewed as an immense challenge; however, recent advances in mechanistic toxicology and computational chemistry can provide great insight into minimizing adverse biological effects. Computational chemistry has revolutionized drug discovery over the past two decades by providing rational means to optimize biological activity by systematic changes to the molecular structure of drug candidates. Some of the same methods can be used to minimize activity of commercial chemicals against specific biological targets. The CADRE approach capitalizes on the insight provided by drug discovery and modeling of organic and enzymatic reactions. The CADRE-SS variant assesses the skin sensitization potential of chemicals, and informs design of safer alternatives to replace potent sensitizers. Skin sensitization is an important, and a well-understood and characterized adverse outcome pathway; however, publically available data suitable for model training is limited compared with other endpoints. As a result, existing structure-based models have struggled to uphold their reported internal performance metrics in external validation studies. In contrast, CADRE-SS relies on direct modeling of molecular interactions rather than structural descriptors, circumventing the need to deconstruct the molecular structure into individual features, and thus avoiding the necessity for a large training set of structural analogs. In external validations, CADRE-SS consistently achieves above 90% concordance with experimental human and animal tests. Most recently, CADRE-SS was successfully tested on a large dataset of APIs and drug intermediates, which typically present an immense challenge from the modeling perspective due to conformational and functional complexity.

## 553

### Identification of potential environmentally hazardous pharmaceuticals by QSAR modeling

A. Sangion, DiSTA; S. Cassani, University of Insubria / DiSTA; E. Papa, Department of Theoretical and Applied Sciences; P. Gramatica, University of Insubria / DiSTA

In the recent years pharmaceuticals have been reported to be ubiquitously present in aquatic and terrestrial environment with the possibility to interact and manifest their biological activity on the wildlife. Little is known about pharmaceuticals environmental behaviour and ecotoxicity so that EMEA (European Medicines Agency) released a guideline for the environmental risk assessment of human pharmaceuticals. As part of hazard assessment we propose the characterization of the intrinsic hazard potential of pharmaceuticals by application and development of QSAR (Quantitative Structure-Activity Relationship) models. First of all we screened more than 400 pharmaceuticals for their potential for persistence in the environment, bioaccumulation and toxicity to fish (i.e. PBT behaviour), also taking into account information on potential for biotransformation to highlight chemicals which have the highest intrinsic potential of being found in the environment. Then we characterized these chemicals for their ecotoxicity, by searching data for algae, Daphnia and fish toxicity to represent a simplified aquatic ecosystem at different

trophic levels. The available experimental data were filtered and used to build *ad hoc* QSAR and QAAR (Quantitative Activity-Activity Relationships) models, which were applied to predict the missing toxicological information. Finally, Principal Component Analysis (PCA) was applied to combine predictions by the different models to screen the most environmentally hazardous pharmaceuticals according to their toxicological profile in the different organisms. This study showed how in-silico models can be applied in the hazard assessment procedure to perform preliminary screening and prioritization of chemicals, and how structural based models can maximize the information contained in existing experimental data. Moreover the identification of the structural features mainly associated with the potential PBT behaviour of the prioritized pharmaceuticals is particularly relevant to perform the *rational design of new, environmentally safer, pharmaceuticals*.

## 554

### Targeted re-design of pharmaceuticals for improved aquatic biodegradability - the example of Atenolol

T. Rastogi, Leuphana Universität Lüneburg / Institute of Sustainable and Environmental Chemistry; C. Leder, Leuphana Universität; K. Kuemmerer, Leuphana University Lüneburg / Institute of Sustainable and Environmental Chemistry

Micro-pollutants have gained more attention in the scientific community. Pharmaceuticals constitute an important group of micro-pollutants that threaten the water resources. The most extensively discussed strategy for the prevention of the input of pharmaceuticals into the aquatic environment are advanced effluent treatment processes. However, these processes have their limitations and drawbacks each such as the formation of toxic and stable reaction products and their very limited possibility of application on the global scale. Chemical and pharmaceutical products should be designed so that at the end of their function they break down into innocuous degradation products and do not persist in the environment. “Benign by design” is the key element in this respect. It is an important concept within green and sustainable pharmacy and chemistry and very promising in terms of sustainability. The concept of “benign by design” can be applied on two levels: the design of completely new molecules or the re-design of existing molecules. In both cases, small alterations in the chemical structure of an API may have a significant impact on the one hand on its activity, solubility and polarity and on the other hand on biodegradability. Re-designing such biodegradable drugs is a challenge that is addressed in the research presented here. Photolysis was used as a tool to synthesise derivatives (i.e. transformation products, TPs) of the drug. These TPs were then assessed for their biodegradability employing the Closed Bottle test (OECD 301D) in combination with liquid chromatography coupled to mass spectrometry (LC-MS/MS). Thereby the biodegradable TPs were identified. In the next step their drug likeness and toxicity as well as their pharmaceutical activity was assessed employing a set of different in silico tools. Photo TPs which were found to be comparatively more biodegradable than the parent compound and other drug-like and non-toxic TPs were identified. However, some of these shortlisted derivatives possessed non-preferred functional groups such as aldehydes that are non-preferred due to their toxicological potency and adverse effect in the human body or as imines (non-preferred due to their instability). However, some promising, environmentally drug-like candidates could also be identified.

## 555

### Influence of functionalization in the toxicity of nanosurfactants to the duckweed Lemna minor

N. Martins, University of Aveiro, Department of Biology & CESAM / Department of Biology; J.L. Pereira, University of Aveiro / Department of Biology and CESAM; C. Duarte, University of Coimbra; L. Dias; F. Antunes, University of Coimbra; I. Lopes, University of Aveiro / CESAM Biology Department

As nanotechnology grows, so does the concern on its environmental impacts. With new international policies pointing towards new approach for the development of new nanomaterials (NMs) that strongly considers their environmental friendliness, the necessary arena has been built to avoid the errors made in the past by the classic chemical industry. NMs can be found in a large variety of applications and some have the scope for an almost limitless range of options in their composition. As the remarkable benefit this may represent, provided that the structure of a given NM can be tuned to perform exactly as required for a given application, the environmental risk assessment stage needs to adjust to such an overwhelming load. Performing early-warning ecotoxicological testing trials at early stages of product development should prevent unnecessary investment in alternative NMs that will be later found to poorly comply with environmental regulation. The present study fits this framework, aiming to assess the influence that functionalization can have in the ecotoxicity of seven variations of soft organic NMs made of biosurfactants. These biosurfactants belong to the class of anionic surfactant and vary in the number of ethylene oxide (EO) units in their head group. The ecotoxicity of each NM variation was assessed using a standard macrophyte growth inhibition test. Growth rates were calculated and used to estimate EC<sub>x</sub> values. Although the overlap of confidence intervals does not allow a clear ranking of toxicity of NM variations, Texapon N701 (exhibiting one of the lowest number of EO units) showed the highest toxicity while Disponil FES77 (exhibiting one of the highest number of EO units) was the least toxic. The focused functionalizations seem to moderately influence the toxicity of

the nanosurfactants to *L. minor*: an increase in the number of EO units seems to reduce NMs toxicity. Further studies are needed to fully understand how NMs functionalization may help nanotechnology to create more environmental friendly solutions while retaining their desired functions.

#### **Estimation of Octanol Water Partition Coefficients and Skin Permeability Exclusively from Spectroscopic Data**

A. Voutchkova-Kostal, George Washington University / Chemistry Department; N. An, George Washington University / Department of Chemistry  
The rational design for safer chemicals requires tools for predicting bioavailability and toxicity that can be used seamlessly by chemists alongside traditional synthesis and characterization. We have developed a series of Quantitative Spectrometric Data-Activity Relationship (QSDAR) models that predict octanol/water partition coefficient (logP) and skin permeability (logKp) of organic chemicals using only NMR spectra. The advantage of these models over traditional structure-based in silico methods is that (a) they do not require knowledge of exact structure and (b) they are applicable to mixtures and formulations in addition to pure chemicals. The models achieve excellent predictive power ( $R^2 > 0.85$  and  $Q^2 > 0.75$ ) and have been thoroughly externally validated. Each model has been trained on a large training set with highly diverse structures. \n

### **Reflections on bird and mammal risk assessment: past, present and future**

557

#### **EFSA 'Risk Assessment for Birds and Mammals' guidance document - the future**

R. Sharp, EFSA - European Food Safety Authority / Pesticides Unit; M. Arena, EFSA - European Food Safety Authority / Pesticides; D. Auteri, Auteri / Pesticides Unit; A. Ippolito, EFSA - European Food Safety Authority / Institute for Environment and Sustainability IES; F. Streissl, EFSA / Pesticides Unit; C. Szentes, Pesticides Unit

In order to gain EU Level approval of an active substance under Regulation (EC) 1107/2009, it is necessary to demonstrate that there are no unacceptable risks to bird and wild mammals. Since the early 2000's to 2009 the main guidance document used was the 'SANCO/4145 Guidance Document on Risk Assessment for Birds and Mammals under Council Directive 91/414/EEC', European Commission (2002)<sup>1</sup>. However, in 2009 the European Food Safety Authority (EFSA) issued a new guidance document ('Risk Assessment for Birds and Mammals', EFSA (2009)<sup>2</sup>). The guidance and recommendations in the EFSA (2009) document offered many benefits and improvements over the old risk assessment methodology. However, practice in its use has identified certain aspects of the guidance document which often require careful interpretation and often lead questionable proposals being made in the risk assessments presented in the dossiers or the Draft and Renewal Assessment Reports (DARs/RARs). This presentation will provide an analysis of common problems which are encountered when performing a risk assessment using the EFSA (2009) guidance document, discuss areas of the guidance which have been identified to be in need of improvement and also reflect on areas which are working well. The plan for the update of the guidance document will be discussed and, if possible, the timelines will be given.

558

#### **Industry view on the implementation of the EFSA Guidance Document on Birds and Mammals in the EU**

J. Pascual, BASF SE; R. Murfitt, Syngenta Ltd / Environmental Safety; K. Brugger, DuPont Crop Protection; T. Carro, DuPont Crop Protection / Environmental Safety Assessment; M. Ebeling, Bayer CropScience AG EnSa-ETX-TV / Environmental Safety Ecotoxicology; P.J. Edwards, Central Product Safety Dept; M. Foudoulakis, Dow Agrosciences / RSRA ERS; T.B. Fredricks, Monsanto Company / Zoology; B. Garlej; J. Hahne, Bayer CropScience AG; P. Manson, Cheminova AS European Regulatory Office / Global Regulatory Science  
EFSA's Guidance Document on the Risk Assessment for Birds and Mammals (EFSA Journal 2009; 7(12):1438) (EFSA GD) was the first guidance document in the area of ecotoxicology developed by EFSA. Several aspects, both scientific and regulatory, of the new GD were highly debated at the time of discussion and approval of the document by European officials before its official implementation in July 2010. After almost 5 years of working experience on the use of this GD by notifiers and authorities for the evaluation and approval of plant protection products in EU countries, this SETAC session is an excellent opportunity to review how the GD is being used in practice and how the controversial topics identified earlier have been tackled during these years. In this presentation, the regulated industry (i.e., agrochemical companies under the European Crop Protection Association) will present its experience and views on how, on practical, operational, regulatory and scientific terms, this GD is being used in the EU for regulatory evaluations and approvals. Focussing on the scientific and regulatory component, the presentation will include a review focussing on parameters used for refined (higher tier) risk assessments according to the EFSA GD. Among these are: selection of focal species representative of different crops and regions; risk assessment for voles and associated regulatory decisions by regulators; selection of reproductive endpoints

from laboratory studies for refined risk assessments for wild birds and mammals; residues in food items; data availability and analysis for Proportion of Time (PT) data; role of field effects studies as top tier studies for regulatory decisions and current role and acceptability by regulators of modelling.

559

#### **Use of post-authorization field monitoring data to assess the availability of cereal seeds on the soil surface after drilling**

E. Bonneris, R. Barfknecht, Bayer CropScience Aktiengesellschaft, BCS AG-D-EnSa-ETX; P. Adrian, CEHTRA SARL; R. Grau, Bayer CropScience / D-GRA

The risk assessment for Plant Protection Products (PPP) on Birds and Mammals is carried out under the EU regulation 1107/2009 and follows the guidance document issued by EFSA (EFSA 2009[1]). The first tier bird and mammal risk assessment for seed treatments assumes that the diet of granivorous species consists entirely of readily available, freshly treated seeds. Many pesticides, used as seed treatments, fail to meet the standard regulatory triggers for acute and long-term risk to birds and mammals and hence require refinement. At higher tier, after selection of suitable focal species, the risk is contextualised by estimating the area that would need to be foraged for a bird or mammal to exceed the acceptable dose. Indeed, different options for refinement are available, including field studies and monitoring surveys where exposure to remaining treated seeds is assessed. Currently, there is limited published information on the density of seeds available on the soil surface, which covers the various agricultural practices of farmers during drilling in Europe. Post-authorization field data have been generated and may be useful to assist in the regulatory decision-making process. In 2011, precise seed countings were performed in autumn during cereal drillings on 86 fields of wheat and barley (773 ha) in different locations covering the main regions cultivated for cereal production in France. The program was also designed in order to assess the possible relationship between seed availability and different agronomic parameters. Variables such as soil humidity, presence of stones, soil type, preparation of the soil prior seeding, drilling depth, drilling speed, and seed density were recorded and evaluated. The outcome of this large-scale monitoring exercise will be compared to and interpreted in perspective of existing literature on the subject and in taking into consideration the current exposure assumptions used in the bird and mammal risk assessments. [1] European Food Safety Agency; Guidance Document on Risk Assessment for Birds and Mammals on request from EFSA (Sanco/10997/2009). EFSA Journal 2009 7(12): 1438 [358 pp.]; Available online: [www.efsa.europa.eu](http://www.efsa.europa.eu)

560

#### **Arena studies offer a more realistic worst case scenario test system than conventional housing for Wood mouse ecotoxicology studies**

N. Dennis, S. Milner, K. Tarrant, Food and Environment Research Agency / Centre for Chemical Safety and Stewardship

Behavioural and consumption studies using singly housed small rodents, such as Wood mice (*Apodemus sylvaticus*), are routinely conducted in small cages such as rat/mouse colony cages that are approximately 28cm wide, 45cm long and 21cm deep. However larger in-door arenas (2.6 x 1.6 x 0.75 m) have been used at the Food and Environment Research Agency (Fera) for consumption and behavioural studies. This test system enables Wood mice to express more natural foraging behaviour over a larger area that is more representative of the natural environment. Wood mouse activity levels are much higher than in smaller cages and therefore energy demands are more characteristic of wild populations. Recent research conducted by Fera have found that Wood mice respond to the challenge of comparable compounds differently if housed in arenas instead of standard cages. It appears that arenas can offer a more realistic "worst case scenario" required for risk assessment. Furthermore, arenas can provide data at a population level. In addition, arenas can be partitioned and through remote sensing can generate data on movement patterns and "field use" in a controlled environment that could provide an ideal bridge between laboratory and full scale field trials.

561

#### **Do insectivorous birds change their foraging strategy after insecticide application in orchards in UK and Spain?**

M.M. Benito, Wildlife Ecology; B. Giessing, Tier3 Solutions GmbH; R. Dittrich, Tier3 Solutions GmbH / Wildlife Ecology; A. Aponte Fernandes, F. Sotti, Tier3 Solutions GmbH; S. Norman, RidgewayEco; N.N. Poletika, Dow Agro Sciences LLC / Field Exposure and Effects Department; C. Wolf, Tier3 Solutions GmbH  
Birds decide constantly about the pattern of use of available resources (e.g. food sources) and react to changing circumstances. Using radio-telemetry, we studied daily home ranges in citrus (Spain) and apple orchards (UK) before and after spraying of the broad-spectrum insecticide chlorpyrifos (CP) in the breeding season. Spatial use of habitats was investigated in response to a sudden temporary decline in arthropod biomass (i.e. food) in the sprayed area. Focal species were the omnivorous Blackbird (BB) and the insectivorous Great Tit (GT) which are both common in citrus and apple orchards. Analysis of faeces allowed us to assess changes in the diet. Birds were radio-tracked before and after CP-application. In Spain, 9 BB and 8 GT were tracked for 57 whole-day sessions. In UK, 7 BB and 10 GT were tracked for 51 sessions. Behaviour and location were monitored continuously. Home range size and overlap between consecutive sessions was calculated, and the distance travelled. In both crops, for both species, daily home

ranges overlapped partially between consecutive sessions (mean 40%, range: 9–73%). In both crops, size of daily home range was stable regardless of CP-application. After application, in both crops, GT spent less time foraging inside the treated area. Also the proportion of treated area within the home range decreased. Travelled distance was unaffected. After application, BB spent more time foraging in citrus. Contrarily, after application, in UK apple orchards BB reduced use of orchards for foraging and the travelled distance increased. These differences for BB between citrus and UK-apples might be due to attractiveness of surroundings. Surroundings of citrus were drier and less attractive for feeding than moister conditions within the citrus which is drip-irrigated. This was different to the wetter off-crop conditions in UK orchards. Only in citrus were trees suitable for BB to nest. If nesting, birds might prefer to keep foraging areas closeby. For both species, content of faeces collected before and after CP-application did not alter. Overall, birds did change their foraging strategy. Food depletion caused by the insecticide was compensated by spatial change of the foraging area rather than change in diet. Birds used parts of their daily home ranges constantly and other parts temporarily. This flexibility allowed adaptation to a temporary reduction in arthropod biomass following insecticide application.

## 562

### **Key drivers of avian breeding-success in chlorpyrifos-treated citrus (Spain) and apple orchards (UK).**

R. Dittich, Tier3 Solutions GmbH / Wildlife Ecology; Z. Gao, F. Sotti, B. Giessing, Tier3 Solutions GmbH; S. Norman, RidgewayEco; N.N. Poletika, Dow Agro Sciences LLC / Field Exposure and Effects Department; C. Wolf, Tier3 Solutions GmbH

It is challenging to balance environmental effects of pesticides with the need for food. Hence, it is important to assess the reality in the field and measure directly the effects from actual use to reach evidence-based decisions. Our study evaluated factors which influence reproduction of birds nesting in citrus (Spain) and cider-apple orchards (UK) including spraying of broad-spectrum insecticide chlorpyrifos (CP) in the breeding season. Potential influence of CP in comparison with effect of habitat, ecological factors, and weather was assessed. Reproduction was measured by counting active nests and no. of fledglings. Effect of predation was explored. Nest searches were conducted in 3 to 4 consecutive years. No. of sites varied from 5 to 10 depending on country & year. Nest boxes (500 per country) were installed to give insectivores Great Tit and BlueTit increased chance to breed in orchards to maximise potential to detect effects of CP. Where nests were empty earlier than expected all signs (shells, body parts, tracks of predators) were recorded to judge cause of failure. Cameras were used for some nests. A logistic-exposure model was applied to identify key drivers of nest survival. **Citrus/Spain:** 602 nests of 14 species were monitored. Most common were Blackbird, Serin, Greenfinch and Great Tits. A third of nests were successful. Great Tits had highest breeding success with mean of 4.3 and 3.4 young per nesting attempt in 2011 and 2012. For open nesters, e.g. blackbird, 0.7 and 1.2 young per nesting attempt were found. Some nests were destroyed by pruning. In citrus, CP-application is relatively late in breeding season. Hence, only 18% of nests was exposed. For Blackbird, nest survival probability was decreased in two sites by CP-application, but this species still reproduced successfully and was abundant. **Apples/UK:** in 2012, nests of 19 species were found in orchards (n = 70) and surroundings (n = 53). 64% inside orchards successfully fledged while 47% in surroundings were successful. With nests boxes, breeding attempts in orchards increased to 153 in 2013. In 79% of nests inside orchards, fledglings were produced. In surroundings 31% of attempts were successful. Inside orchards 4.9 young per nesting attempt and in nests found in surroundings 2.2. young were produced. **Overall,** predation of nests and increasing date of breeding-attempt were found to be the key drivers of breeding-success in citrus and cider-apple orchards.

## **Risk assessment, risk management and mitigation for pesticides: from regulation to public perception (III)**

## 563

### **Harmony in the Southern Zone: Was France a good contributor to the regulatory symphony?**

A. Boivin, V. Poulsen, ANSES

Risk assessment for plant protection products (PPP) is performed according to regulation 1107/2009 [1]. European countries were distributed within three zones: the Northern, the Central and the Southern zone including France. The current PPP risk assessment procedure implemented at zonal level mimic the procedure used for active substances at European level. The final zonal registration is produced based on the draft as proposed by the zonal rapporteur member state and the comments from the concerned member states. The commenting period has been crucial during the implementation of the zonal approach since it has been identified as the unique opportunity for member states to interact. According to the new regulation, one member state of the zone, the zonal Rapporteur Member State (zRMS) takes the lead on PPP risk assessment. The zRMS has to insure that the risk assessment as presented would fit for all member states of the zone. Ideally, every member state of the zone is able to use the risk assessment as proposed by the zRMS to finalise the risk assessment at national level (mutual recognition). As a consequence the zonal approach has transformed the risk assessment work. The challenge is to share a

common dossier that would include an agreed risk assessment (e.g. European Food Safety Authority conclusions) and potentially additional risk assessments in order to fit with specific member states requirements or enforcements, southern ones in its case This presentation provides feedbacks from ANSES on regulation 1107/2009 implementation. Examples on the consequence on exposure and ecotoxicological risk assessment methodologies are presented. In addition, aspects regarding the current articulation of southern zonal dossiers to fit with southern member states requirements are presented. Details on the harmonisation procedure and proposal for future improvement are mentioned.

## 564

### **Biodiversity in monitoring studies investigating the efficacy of risk mitigation measures in the farmland - a review**

A. Alix, Dow Agrosiences / Risk Management; C. Garrido, BeeSafe; B. golla, Institute for Strategies and Technology Assessment; M. Miles, Bayer CropScience UK / Environmental Safety

The registration process for Plant Protection Products (pesticides) in agriculture relies on a preliminary evaluation of the risks they may pose to human health and the environment, among which honey bees and other non-target arthropods in the farmland [1]. If necessary, specific risk mitigation measures may accompany the registration in providing detailed conditions of use to reduce pollinators' exposure [1]. In addition, the reform of the European Common Agriculture Policy (CAP) includes the implementation of ecological focus areas, which should represent at least 5% of the arable area of the holding for farms with an area larger than 15 hectares (excluding permanent grassland) – i.e. field margins, hedges, trees, fallow land, landscape features, biotopes, buffer strips, afforested area [2]. This figure is to rise to 7% after a Commission report in 2017 and a legislative proposal. The objective of these two sets of measures present commonalities, particularly with regards to biodiversity. In the context of the registration process of pesticides, it must be ensured that their use does not exert unacceptable effects on a range of protection goals, including biodiversity [1] and risk mitigation measures, when necessary, aim at achieving this goal. These risk mitigation measures are reported on the labelling of pesticide products [3]. The ecological focus areas presented in the CAP aim at restoring or preserving biodiversity in the farmland. Therefore although the measures adopted may take different forms, they are targeting a common benefit on biodiversity, which has therefore been measured in a number of studies dedicated to the evaluation of the efficacy of farmland management plans at improving biodiversity in cultivated areas [4]. This presentation will illustrate the outcome of the review on the efficacy of risk mitigation measures at preserving and/or restoring biodiversity in cultivated areas, undertaken during the MAGPIE workshop, and discuss this outcome in relation to risk mitigation measures and risk assessment applied to pesticides.

## 565

### **Pesticide risk mitigation at landscape level (RISKMIN) - A spatial approach to maintain and develop agrobiodiversity**

B. Scholz-Starke, RWTH Aachen University, Institute for Environmental Research / Institute for Environmental Research BioV; M. Trapp, RLP AgroScience, IfA / Institute for Agroecology; M. Deubert, L. Streib, RLP AgroScience GmbH; A. Toschki, Research Institute gaia; C. Kula, Fed. Office for Consumer Protection & Food Safety; M. Roß-Nickoll, RWTH Aachen University / Institute for Environmental Research

Nowadays, it is widely accepted, however controversially discussed, that species diversity and habitats quality dramatically decrease with increasing intensity of agricultural land-use. Therefore the current off-crop mitigation tools to avoid unacceptable risk from the use of pesticides are critically reviewed. Complementary landscape level mitigation options to protect non-target biodiversity in Germany are considered. An approach is presented that considers the real landscape structure by classifying the landscape elements according to their biodiversity of various arthropod groups. The project RISKMIN includes an 'ecological value' depending on spatial distribution of typical elements of terrestrial agricultural landscapes in Europe, exemplified by two regions in Germany. The assessment of the efficacy of landscape-level mitigation measures, such as extensification or providing a higher variety of structural elements is analysed. The RISKMIN project is organised as a modular and interdisciplinary approach. Firstly, the module GEODAT defines 50 types of ecologically relevant landscape elements (LE-types). To each of the elements an ecological value between 0 and 100, derived from impact regulation closely related to the biotope type is assigned, which reflects the natural value of the respective element. Advanced remote sensing using geographic information systems identifies the shapes of landscape elements and collects (geo-) data that is necessary to allocate LE-types to the shapes. An integrated landscape ecological value is calculated as the sum of all ecological values of the single LE (module STATUS QUO), which is then corrected for intensive agricultural use for LE nearby in-crop areas. The module PROJECTION then identifies and defines most promising risk mitigation measures (RMM) of different mechanisms and implements rules for mechanisms of melioration at landscape level. The methodology is considered well established but needs calibration by data from different landscapes. The model that was derived from the RISKMIN project puts the discussion on landscape-based RMM a step forward. We implement the fact that intense agricultural practices come along with undesired side-effects in the long term and thus lead to a significant downgrade of the landscape status compared

to past reference state. The RISKMIN concept recommends options for risk managers especially to optimize RMM alongside with national programs for sustainable land use.

#### **Can we make balanced decisions? Always look on the bright cider life**

S. Deacon, ENVIRON UK Ltd; S. Norman, RidgewayEco; M. Rockel, ENVIRON International Corp.; P. Burston, ENVIRON; L. Sanderson, N. Eury, ENVIRON UK Ltd; F. Cnudde, Dow AgroSciences LLC

Regulators at EU and Member State level face the challenge of having to make decisions on plant protection products (PPP) using environmental risk assessments, which do not include information on benefits. In particular, evidence on how a particular plant protection product affects the socio-economics of farming is currently not part of the decision-making process. Regulation 1107/2009 states 'The purpose of this Regulation is to ensure a high level of protection of both human and animal health and the environment and at the same time to safeguard the competitiveness of Community agriculture'. The latter element is recognition that a regulatory decisions on a PPP should not made 'in a vacuum', especially if there is no evidence of harm to non-target populations in the field resulting from its use according to the Good Agricultural Practice. The authors have undertaken a number of cost-benefit analyses to evaluate the use of a range of PPPs and crops. Their approach provides a holistic basis for making pragmatic and practical decisions in a transparent manner. When maximising agricultural land for food production, ecosystem services analysis and socio-economic assessment of farming can emphasise trade-offs in these services. Decisions can then be made using environmental, social and economic evidence. The paper gives an overview of potential implications of not taking holistic decisions. For example, growers rely on crop protection tools. When this 'toolbox' is threatened by regulatory decisions, pest resistance, and new policies based on hazard instead of risk, then products may be removed from the market. If there is no alternative active substance or if the outcome is an over-reliance on one mode-of-action – leading to pest resistance – cultivation of some crops may no longer be competitive. This can lead to changes in practices or even land-use itself. These changes also influence ecosystem services, which may be decreased – i.e. a worse situation – compared with before the regulatory action. The use of ecosystem services in PPP regulation will be presented and illustrated by a case study where the use of an insecticide in cider apple production in UK has been evaluated.

567

#### **Risk Assessment on Natural Organisms of Organic Farming Materials from Plant Extracts for pest Control in Korea**

J. Oh, NAAS, RDA / agrofood safety; K. Park, NAAS, RDA / Chemical Safety Division; M. Paik, NAAS RDA; S. Han, RDA; J. Jin, NAAS RDA; B. Kim, National Academy of Agricultural Science; S. Hong, National Academy of Agricultural Science / department of crop life safety; N. Cho, NAAS RDA This study was performed to evaluate the risk of the organic farming materials for insect control. In South Korea, neem, sophora and derris extracts are used mostly for organic farming. To evaluate the toxicity of these plant extracts to *Cyprinus carpio*, *Misgurnus anguillicaudatus*, *Apis mellifera* L. and *Eisenia fetida*. We conducted some tests, fish acute toxicity test, honeybee acute toxicity tests, honeybee toxicity test of residue on foliage and earthworm acute toxicity test. According to the acute toxicity tests, neem and derris extracts were very low in toxicity to *Cyprinus carpio*, *Misgurnus anguillicaudatus*, *Apis mellifera* L. and *Eisenia fetida*. Therefore, it is expected that these plant extracts have no significant effects on the environmental organisms when farmers use it for organic farming to insect control. But sophora extracts are making a toxic effect on bees. So the regulatory system about the time and amount of using in farm is necessary on organic farming materials containing sophora extract to protect the bees.

#### **State of the art in mechanistic effect modelling for aquatic risk assessment of plant protection products**

T.G. Preuss, Bayer CropScience / Environmental Modelling; h. haveco, Environmental Risk Assessment Team; A. Focks, Alterra Wageningen University and Research Centre / Ecotoxicology Environmental Risk Assessment Team; U. Hommen, Fraunhofer IME; T. Strauss, Research Institute gaiac / Research Institute Gaiac; P. Thorbek, Syngenta / Environmental Safety Mechanistic effect modelling (MEM) is becoming increasingly important for environmental risk assessment and environmental science. The advantages of MEMs are manifold: They enable the extrapolation of effects between different exposure profiles and provide the potential to integrate necessary ecological knowledge, leading to a more realistic chemicals' effect assessment. The aim of the current presentation is to give an overview on the achieved milestones within the mechanistic effect modelling for aquatic risk assessment. Therefore the available models for aquatic risk assessment will be reviewed based on their validation status, their similarities and differences and their possible use in the risk assessment. Appropriate modelling approaches have to be selected depending on the risk assessment question (e.g. time to recovery of populations, effects on individual level) as well as on the level of biological organisation, namely the individual, population or community level. Therefore the model approach has to be chosen in line with the specific protection goals as defined by EFSA. In order to choose the

right modelling approach it is also necessary to consider the data requirements which is the basic dataset we have to address these specific protection goals. We here present models for all organism groups defined in the aquatic guidance document and show the potential use of these models for common risk assessment questions, like extrapolation from lab to field, from individual to population, to untested exposure situation and to untested ecological scenarios. Here the state of the art model approaches will presented and linked to their domain of applicability in environmental risk assessment of plant protection products. We will demonstrate what can be learned from the models developed so far and suggest a more generic modelling framework. Mechanistic effects modelling will help to incorporate the complexity of the real world into our environmental risk assessment and thereby will be an necessary tool to foster the debate on needed complexity and to set protection goals.

#### **Subway particles: what do we breathe on platforms and in trains?**

T. Moreno, Geosciences; V.I. Martins, M. Mingui  n, C. Reche, Institute of Environmental Assessment and Water Research (IDAEA-CSIC); E. de Miguel, M. Capdevila, S. Centelles, Transports Metropolitans de Barcelona (TMB); X. Querol, Institute of Environmental Assessment and Water Research (IDAEA-CSIC) Commuting by underground rail is a transport mode used daily by over 100 million people worldwide. Published reviews of subway air quality worldwide reveal a wide range of PM concentrations present in underground platforms, and beg the question: why is there such diversity? The air quality of a given subway platform involves a complex interplay of the ventilation system, station depth and design, train speed, frequency, wheel materials and braking mechanisms, and number of passengers being transported. Air movements on the platform show constantly repeated cycles involving turbulent flow through some combination of mechanically forced ventilation systems, blast shafts, and platform access points, driven to a large extent by the piston effect of the trains moving through the tunnels. Narrow platforms with single-track tunnels are strongly dependent on forced tunnel ventilation, in contrast in wider stations with spacious double-track tunnels ambient PM levels can actually improve when tunnel ventilation is switched off, offering the possibility of significant energy savings without damaging air quality. Another variable is that occurring spatially along the platform, with the greatest accumulation of PM usually occurring at one end, depending on station design. Access tunnels can help dilute PM concentrations by introducing cleaner air from outside, although lateral accesses are less effective than those at the train entry point. More interesting than the mass concentration of PM is the fact that platform particles are pervasively ferruginous and commonly accompanied by other elements such as C, Si, Ca, Mn, Cr and Ba. They are both physically and chemically different from the typical outdoor urban cocktail of inhalable PM breathed above ground in the city. These subway particles display a spectrum of morphologies but by far the most common occurs in the form of irregular, rough-surfaced flakes measuring at most just a few microns in size, commonly displaying cracked and corroded textures. Thus, the dominant mix of source materials and processes of PM generation are unique to the subway environment. This work is supported by the Spanish Ministry of Economy and Competitiveness and FEDER funds (CGL2012-33066, METRO), EU (FP7 grant 315760 HEXACOMM) and IMPROVE LIFE project (LIFE13 ENV/ES/ 000263).

#### **Measuring PM<sub>2.5</sub>, particle number and black carbon concentration on the London Underground**

F. Kelly, Kings College London; J. Smith, D. Green, S. Beevers, B. Barratt, Kings College London / MRCPHE Centre for Environment and Health The London Underground is a mostly subterranean railway system consisting of 402 km of track that carries over 1.2 billion passengers per year in the Greater London region (Transport for London, 2014). Passenger exposure is under-researched, limited to occupational-health research which has focused on drivers' shift-time exposure, and a small number of studies typically focused on comparing urban transport modes. Adams et al. (2001) sampled on the Bakerloo, Northern and District lines measuring PM<sub>2.5</sub> concentrations. Seaton et al. (2005) sampled on the Central, Northern and Victoria lines, and at three stations, measuring PM<sub>2.5</sub> and particle number concentration. In a new study we placed personal monitoring equipment (Aethlabs AE51 microAeth, TSI Sidepak AM510 and Phillips Aerasure Nanotracer) in the driver's cabin, and simultaneously in the

passenger's cabin, to measure PM<sub>2.5</sub>, particle numbers and black carbon concentration across the entire network. We complimented this with a 'fixed site' on the platform of Hampstead Station to provide calibration for the mobile equipment. By manually completing a time-location diary, we were able to examine differences in concentrations by line, line-depth, underground v. uncovered, and passenger cabin v. driver cabin. The findings from this study will be presented at SETAC Europe 2015. References: Adams, H.S., Nieuwenhuijsen, M.J. & Colvile, R.N., 2001. #### **Nanomaterial release data for LCI and derivation of nanomaterials impact factors for LCIA: Nanopolytox case studies**

D. González, Leitat Technological Center; C. Hidalgo, Leitat Technological Center / RD Safety Sustainability Division; G. Janer, Acondicionamiento Tarrasense; E. Fernández-Rosas, G. Vilar, Leitat Technological Center; M. Escamilla, LEITAT / Sustainability Unit; S. Vázquez-Campos, Safety Sustainability  
The increasing use of nano-enabled products has brought controversy due to the lack of data on their potential impact on human health and environment. On that concern, there is a consensus that Life Cycle Assessment (LCA) is a suitable method to assess the environmental performance of this new technology, but the number of studies that generate data for the Life-Cycle Inventories (LCI) is very scarce, most of them focus only in the manufacturing step (cradle-to-gate studies) and the impacts of released NM are usually neglected. So, LCA for nanotechnologies is challenging since there still are a lot of uncertainties and data gaps. The NanoPolyTox project was designed to propose a methodology to determine the Human Health (HH) and Freshwater Ecosystem (FE) impacts due to the release of NM during the whole nano-enabled product value chain; further apply this methodology to derive the impact factors of nanocomposite applications; and, finally, include these impact factors in a complete cradle-to-grave LCA study. In order to determine such HH and FE impacts, a combination of release determination over the different life-cycle stages (NM synthesis, nanocomposite production, use and recycling/disposal) and characterization factors was performed for three polymeric nanocomposites for outdoors applications (MWCNT-PP, TiO<sub>2</sub>-PA, ZnO-EVA). NM releases were determined based in the literature for the manufacturing and experimentally for the other stages. Accelerated aging conditions were used to evaluate the release of nanomaterials and possible transformations during the use phase, and recycling and end-of-life processes were also tested to evaluate possible transformations occurring on the nanomaterials. For the characterization factors, USEtox® was used as starting point; we have developed a general methodology to derive fate, human health and ecotoxicological factors for nanomaterials. On one side, fate and intake models were adapted to NM exposure factors determination. On the other, different approaches were considered for human health hazard and ecotoxicological factors derivation depending on the availability of data. Different variables can dramatically change the hazardous effects of a nanomaterial. Therefore, decision criteria were suggested on how to select input data for these factors. Despite these particularities, the general concept and methodology around the derivation of human and ecotoxicological effect factors are however unchanged.

575

#### **Comprehensive LCI and LCIA modelling for nanomaterials and its influence on study results – the case of Nano-TiO<sub>2</sub>**

R. Hirschier, EMPA / Technology and Society Lab; B. Salieri, EMPA / C.I.R.S.A.; M. Pini, University of Modena and Reggio Emilia / Department of Sciences and Methods for Engineering

A couple of review studies in the last 5 years (e.g. Hirschier and Walser, 2012, Miseljic and Olsen, 2014) have shown, that the application of LCA in the area of nanotechnology currently presents three major weaknesses and thus challenges: (i) the choice of an adequate functional unit, taking into account all functionalities that a new product version, containing engineered nanomaterials (ENM), shows in comparison to a traditional option, (ii) the availability of adequate, consistent and complete life cycle inventory (LCI) data for the production of the applied ENM, and (iii) the availability of impact assessment characterisation factors, especially concerning human toxicity and ecotoxicity for releases of nanoparticles along the life cycle. However, so far the question is open, which of these three above mentioned challenges / points has the biggest influence on the results of an LCA

study; LCA study in which not the ENM, but the application case is the central view of investigation. This question is investigated by using the case of nano-TiO<sub>2</sub>; one of the most relevant and most sold ENM on the market (Piccinno et al., 2012) – and in the same time one of the most comprehensively examined ENM with LCA (see e.g. Pini et al., 2013, Salieri et al., 2015, Pini et al., 2015, or Hirschier et al., 2015). Various application cases – paints, glass coating, ceramic tiles, etc. – and several production pathways for the synthesis of this ENM have been reported in the last couple of years; however, no comparison between e.g. these various production pathways – and the consequences on the results of an application case – can be found so far in the literature. Similar situation concerning the assessment of releases of nanoparticles of TiO<sub>2</sub> into the environment – the recent literature reports several different approaches/procedures, but again, no comparison of these approaches can be found. This presentation in the special session “LCA of nanotechnology-based products” will show the results of the currently on-going comparison of these various LCI models for the nano-TiO<sub>2</sub> production and of the different LCIA characterisation factors that have been established in the recent past by applying this range of LCI resp. LCIA data on some of the published case studies mentioned above. **References** Hirschier R, Nowack B, Gottschalk F, Hincapié I, Steinfeldt M, Som C (2015) Life Cycle Assessment of Façade Coating Systems containing Manufactured Nanomaterials. *Journal of Nanoparticle Research* 17 (68):13 pp. doi:10.1007/s11051-015-2881-0 Hirschier R, Walser T (2012) Environmental Sustainability Assessment of Engineered Nanomaterials: State of Art & Strategies to Overcome Existing Gaps. *Science of the Total Environment* 425:271–282 Miseljic M, Olsen SI (2014) Life-cycle assessment of engineered nanomaterials: a literature review of assessment status. *J Nanopart Res* 16 (2427):33 pp. doi:10.1007/s11051-014-2427-x Piccinno F, Gottschalk F, Seeger S, Nowack B (2012) Industrial production quantities and uses of ten engineered nanomaterials in Europe and the world. *J Nanopart Res* 14 (1109):11 pp. Pini M, Cedillo González EI, Neri P, Siligardi C, Ferrari AM Life cycle assessment of nanoTiO<sub>2</sub> coated self-cleaning float glass. #### **Sustainability Check of nano-enabled products and applications**

M. Möller, Oeko-Institut e.V / Division Sustainable Products and Material Flows  
As part of the current debate on the opportunities and risks of nanotechnology, the need to quantify possible contributions to sustainable development is becoming increasingly important. Against this background, the Nano-Sustainability Check developed by Öko-Institut provides an instrument offering an integrated approach relative to sustainability aspects of nano-enabled products and applications throughout their whole life-cycle. The approach chosen for this tool allows to serve as a strategic radar system for the management of opportunities and threats, in order to anticipate beneficial effects for the environment and to identify new markets on the one hand, and on the other to avoid bad investments and dangers to the society. With the help of the Nano-Sustainability Check, companies that develop or produce nano-enabled products and applications can carry out a self-evaluation of their own business activities. The most important feature in this context is an evaluation grid by means of which a nano-enabled product or application can be analysed by comparison with an existing reference product that has been manufactured without the use of nanomaterials. In addition, the evaluation grid is able to address any possible threats. The aspects investigated within the Nano-Sustainability Check are represented in the form of a total of 14 key performance indicators. The focus is on aspects of environmental and climate protection, but also user benefits and life-cycle costs are considered. Complementarily, the opportunity / threat analysis takes into account external conditions such as employment effects, societal benefits and risk perception. The results of the individual key performance indicators are combined into a single representation. To this purpose, the "SWOT analysis" originally derived from business administration is adapted as a central tool in the communication of results. Based on the SWOT matrix, recommendations for a strategic optimisation of the investigated object can finally be developed. Their goal is to maximise the potential of strengths and opportunities with regard to sustainability while minimising potential negative effects of weaknesses and threats. Besides the description of the methodological approach, also the results and conclusions from selected case studies of nano-enabled products will be presented. These cover a concrete catalyst as well as electronically dimmable windows.

## Life Cycle approaches for nanotechnology-based products

T. Ligthart, TNO

Nanotechnology often aims to improve the performance, like increase energy efficiency, reduce waste production or reduce the use of scarce resources, of product systems. Although there may be benefits of applying nanotechnology it is also associated with risks for human health or the environment. For a proper consideration of these benefits and risks one cannot focus on a single stage like production or use, only a life cycle approach seems fit to assess all the benefits and risks. Key is that the life cycle approach encompasses all the stages, cradle-to-grave, of a product system. The assessment of the benefits and/or risks may be of a qualitative, semi-quantitative or quantitative nature. In this presentation examples of both qualitative as quantitative methods will be shown. An example of a qualitative tool is LICARA nanoSCAN (LICARA, 2014b). Using the technique of multi criteria decision analysis it presents the user with an overview of both the economic, environmental and societal benefits as well as the environmental risk and public, occupational and consumer health risks. Finally an evaluation the combined benefits and risks is presented. Substance or material flow analysis is a quantitative tool and has the potential to show the flows of a nanomaterial throughout a product system and show the emissions to the environment. The tool focusses on the risks of e.g. nano-TiO<sub>2</sub> (Gottschalk, Scholz, & Nowack, 2010). The tool can be used to identify hot spots of release to the environment. Life Cycle Assessment (LCA) assesses the environmental impacts of all substances in a product system and can compare the environmental impact of the nano-based product system with the conventional one. An example is the assessment of facade coating systems (Hischier et al., 2015). This study showed that nano-based systems may or may not have a better environmental performance than the conventional ones. LCA considers the environmental risks and benefits of nanotechnology-based products but doesn't address economic or societal benefits. The tool for this is socio-economic valuation or cost benefit analysis. An example for a nanosilver coated door handle aimed to reduce the number of hospital acquired infections (LICARA, 2014a) will be shown. The socio-economic valuation uses LCA results to address the environmental aspect, but also includes application costs and the benefit of infection reduction. References: Gottschalk, F., Scholz, R. ### Open discussion

S. Vázquez-Campos, Safety Sustainability

After the overview given by the talks proposed for the session the discussion will be focused on the perspectives in the area of LCA of nanotechnology-based products, mapping the challenges and the gaps and how should we approach them. An important point to cover in the round table discussion is **how to transfer the data/knowledge needs from the LCA experts to the experts in the related areas** (material science, nanotoxicology, fate) to be able to improve/modify the existing LCA tools to be fully applicable to nanotechnology-based products. Therefore, we invite experts from other related areas to participate in the round table discussion of this session.

### Ecological Risk Assessment (ERA) of pesticide run-off from banana plantations into the river and lagoon Madre de Dios in Costa Rica using SSD, msPAF and PERPEST models

R. Rämö, Stockholm University / Dept of Ecology Environment and Plant Sciences D; P.J. van den Brink, Alterra and Wageningen University; C. Ruepert, Universidad Nacional / IRET; L.E. Castillo, Universidad Nacional, Costa Rica / IRET; J. Gunnarsson, Stockholm University / Department of Ecology Environment and Plant Sciences DEEP

Costa Rica faces environmental problems due to high pesticide use in agriculture. In this study, ecological risks to aquatic species from pesticides were investigated in a river and coastal lagoon system on the Caribbean coast of Costa Rica. Three recent ERA approaches were used: SSD, multi-substance PAF (msPAF) and the PERPEST model. The results from each model are presented and compared. Analysis of pesticide residues in over 200 surface water samples at IRET, UNA, Costa Rica within the TROPICA project showed occurrence of 31 pesticides: 8 insecticides, 8 herbicides and 15 fungicides. The pesticides diuron, ametryn, ethoprophos, epoxiconazole, diazinon, pyrimethanil, chlorpyrifos, azoxystrobin, chlorothalonil and difenoconazole were frequently detected (>10% pos. detection). Due to limitations in literature data only 12 of these pesticides were assessed in SSD using data from ≥6 species. Endpoints were LC<sub>50</sub> or EC<sub>50</sub> for sensitive species i.e. primary producers (algae, aquatic plants) for herbicides, arthropods

(crustaceans, aquatic insects) and fish for insecticides and all groups for fungicides. High risk was caused by the organophosphates diazinon and ethoprophos (PAF>0.05). Other pesticides posed lower risk (PAF< 0.05) but hexazinone, oxyfluorfen and chlorothalonil approached 5% species affected. The msPAF assessment was carried out at five sites using data for ≥4 species. Results show that all groups are exposed to pesticide mixtures at a high risk of acute lethal effects (msPAF≥0.05). For primary producers max msPAF ranged from 0.05 to 0.75. For arthropods and fish max msPAF were more similar ca 0.36 at all 4 sites downstream plantations compared to a max msPAF of 0.068 upstream. A pattern emerged in msPAF independent of organism group: highest risk was caused by herbicides, followed by fungicides, and then insecticides. These results are unexpected as insecticides were presumed to be the greatest contributor of toxicity to arthropods and fish. This is a result of herbicides and fungicides outweighing insecticides. These results show that it is essential to study toxicity caused by mixtures in multiple exposure systems. While single substance risk assessment show fairly low risks to sensitive species, mixture toxicity assessments show that organisms in the system are exposed to mixtures that lead to a higher-than-acceptable percentage of species being affected at a 50% mortality level quite frequently.

581

### Predicted fish toxicity risks of pesticides used in paddy rice fields in the Mekong delta, Vietnam, and comparison between different agro-management regimes

N. Stadlinger, Stockholm University / Ecology Environment and Plant Sciences; H. Berg, Örebro University; P.J. van den Brink, Alterra and Wageningen University; N. Tam, Nong Lam University; J. Gunnarsson, Stockholm University / Department of Ecology Environment and Plant Sciences DEEP

Simple risk-assessment procedures are becoming increasingly important in tropical areas where chemical use is increasing, but where little background data is available. There is also less knowledge on fate and effects of the chemicals in tropical areas. The Mekong Delta in Vietnam is an example of an area with highly intensified paddy rice agriculture, where high amounts of chemicals are being applied. There have been studies on pesticide application in the area, but little is known about the effects on aquatic organisms living in adjacent water bodies. In this study we wanted to evaluate if the toxicity risks to fish were different between rice and rice-fish farmers with and without a background in Integrated Pest Management (IPM) and between two provinces. Risks were calculated using PRIMET, a simple model that calculates a risk quotient and a predicted environmental concentration based on a minimum of input parameters and takes into account temperature dependent physico-chemical parameters. The risk was thereafter further characterized using Species Sensitivity Distributions (SSDs) based on published toxicity test fish data (LC<sub>50</sub> acute mortality) in order to derive potentially affected fraction values for fish within the rice paddy. Pesticides with definite risk to aquatic organisms based on a worst-case assumption were alpha-cypermethrin, diazinon, etofenprox, fenobucarb, fipronil, permethrin, phenthoate, quinalphos and the herbicide fenoxaprop-P-ethyl. Whereas the province of Can Tho applied lower amounts of pesticides, the toxicity risks were higher for all management regimes compared to Tien Giang. The results from SSDs show that farmers cultivating fish often have lower toxicity risks in their rice fields compared to non-fish farmers. However, risks were generally high with a substantial part of the fish population being affected. This study did not evaluate toxicity of pesticide mixtures or indirect effects that would likely enhance the risks to fish. The high toxicity risks found in this study could explain why integrated rice-fish systems have not been so successful over time. The pesticides do not only pose a threat to farmed fish but also to native aquatic species. The insecticide use in Southeast Asia has not changed much in rice-fish farming, with the same substances being used today as three decades ago. For more successful integrated rice fish systems, the chemical input has to be reduced and the most toxic pesticides replaced.

582

### Combining tissue-level biomarkers and chemical analysis to assess ecosystem health in Caribbean mangroves: relevance for pollution monitoring

J.R. AGUIRRE RUBI, Univ. Basque Country (UPVEHU) / Dept Zoology Animal Cell Biology; A. Luna Acosta, University Jorge Tadeo Lozano of Bogota UJTLB / Dept of Marine Biology; L. Garmendia, University of the Basque Country / Zoology and Animal Cell Biology; N. Etxebarria Loizate, University of the Basque country UPVEHU / Dept of Analytical Chemistry; M. Ortiz Zarragoitia, B. Zaldibar Aramburu, M. Soto Lopez, U. Izaguirre Aramayona, University of the Basque country UPVEHU / Dept of Zoology and Animal Cell Biology; J.F. Espinoza, National Autonomous University of Nicaragua / Dept of Microbiology; L.M. Villamil Diaz, University Jorge Tadeo Lozano UJTLB / Dept of Marine Biology; M.J. Ahrens, Universidad de Bogotá Jorge Tadeo Lozano; I. Marigomez Allende, University of the Basque country UPVEHU / Dept of Zoology and Animal Cell Biology

Nowadays, the established monitoring programs at regional level in the Caribbean coast are just focused on chemical endpoints (e.g. Reducing pesticide runoff to the Caribbean (GEF-REPCAR, 2007-2011) and Heavy metals accumulation in the Caribbean (under an IAEA Technical Cooperation project (RAL/7012), 2007-2012)) including chemical distribution of contaminants in bivalves' tissue, sediment and water. But the aimed of the present study was to screen and

understand a battery of biological effects parameters as relevant tools for the assessment of the ecosystem health status. For that, a pilot biological effect monitoring program was launched in 3 localities of Nicaragua and 5 localities of Colombia in 2012-2013, using *Crassostrea rhizophorae* as sentinel species. The localities were chosen according to different levels and sources of contaminants. Samples were collected both in the rainy and dry seasons and a battery of biomarkers at tissue-level, gamete developmental stages and stress on stress (SoS) were measured along with chemical analysis in each locality and sampling time. In the Nicaraguan localities, SoS showed that those oysters collected near urban areas were less sensitive than those ones collected further, being able to survive 1-2 days more. Likewise, differences in gamete developmental stages, histopathological alterations and metal body burdens were recorded between oysters collected from Half and Pigeon Cay (localities near urban areas) and Punta Lora (reference locality). Overall, even the observed tissue alterations and metal levels were under threshold values, differences between localities and season could be detected. In the Colombian localities high concentrations of Cd, Cu and Zn were recorded, with significant differences between localities. In concordance of chemical data, studied biomarkers showed significant differences between localities. These results are the first approaches in an attempt to study the ecosystem health status in the selected localities to better understand and design a biomarkers-based pollution monitoring program in the Caribbean, and especially in mangroves.

### Effects of the mixture of herbicides ametryn and tebuthiuron on antioxidative defenses in juvenile tilapia (*Oreochromis niloticus*)

M.A. Moura, Instituto Biológico / Laboratório da Ciência das Plantas Daninhas; F.G. Sampaio, Embrapa Meio Ambiente; Z. Clemente, Embrapa Meio Ambiente / Embrapa Environment; D.A. Monteiro, Universidade Federal de São Carlos / Departamento de Ciências Fisiológicas; F.T. Rantin, Federal University of São Carlos (UFSCar) / Department of Physiology; C.M. Jonsson, Embrapa - Brazilian Agricultural Research Corporation / Embrapa Environment

Metallothioneins (MT) are non enzymatic proteins with low molecular weight and high cysteine concentration. The induction of MT synthesis has been described in various animal groups in response to contamination by metals, pesticides and industrial effluents, suggesting the potential use of MT concentration as a biomarker. Antioxidant enzymes, such as catalase (CAT), play a major role in reducing the oxidative stress by removing the reactive oxygen species (ROS) induced by pollutants on fish. This study assessed the activities of MT and CAT, respectively in gills and liver, of tilapia (*Oreochromis niloticus*) exposed to the mixture of the herbicides ametryn and tebuthiuron (1:0.6, respectively). These compounds are widely used in sugarcane crops, one of the predominant cultures in Brazil. Fish were exposed during 14 days to the mixture of herbicides ametryn + tebuthiuron (control, 0.1076 and 1.076 mg L<sup>-1</sup> active ingredient), both in the form of commercial products in concentrated suspension containing 50% a.i.. Tests were conducted in duplicate by the exposure to 1/100 and 1/10 of LC<sub>50-96h</sub> during 14 days, followed by a same period of depuration in water without the herbicides. Fish (Ls = 9.98 ± 0.56 cm; Wt = 33.48 ± 6.15 g) (n=36) were fed *ad libitum* and maintained in tanks of 115 L with aeration, in a density around 3.8 g L<sup>-1</sup>, in room with temperature (26.0 ± 2 °C) and photoperiod (16:8h, light: dark) control. The concentration of MT in gill increased significantly in fish exposed to the highest concentration of AMT + TBUT mixture for seven days. After this period, the activity of this non-enzymatic antioxidant was reduced, with a more pronounced decrease in seven days of depuration (p < 0.05). The activity of CAT was decreased in 44.6% compared to the control (p < 0.05) in fish exposed to the lowest concentration tested in 14 days of exposure. This is consistent with the gradual accumulation of products in fish tissues and the increase of exposure time. Our results indicate the negative impact of the mixture of herbicides AMT + TBUT on tilapia physiology, as well demonstrate an herbicide-induced adaptive response in this tropical species. Furthermore, these enzymatic and non-enzymatic tissue antioxidants serve as surrogate markers of exposure to oxidant pollutants in fish. These results may also be useful for the establishment of maximum herbicides concentrations limits in water bodies.

## 584

### Soil Ecotoxicology in Brazil: where we are, where to go

C.C. Niva, Embrapa Cerrados; J.C. Niemeyer, Rua Prof. Sabino Silva / Department of Life Sciences; F.M. Rodrigues da Silva Júnior, Laboratory of Pharmacological and Toxicological As; M.T. Nunes, Universidade de São Paulo / Hidráulica e Saneamento; J. Roembke, ECT Oekotoxikologie GmbH

The first publications on soil ecotoxicological tests using soils organisms in Brazil can be dated from the beginning of the 21st century as a result of the increasing consciousness of the researchers on the importance of soil compartment. The number of groups working on soil ecotoxicology has increased significantly since then. Here, we present the state of art and advances of soil ecotoxicology in Brazil and discuss the needs for the improvement of tropical ecotoxicological tests. The information presented here were based on studies in soil ecotoxicology developed in Brazil found in peer-reviewed papers and also thesis, dissertations and congress abstracts which contain important data on the activities going on in the country. Originally, ecotoxicological tests have been applied in temperate regions mainly for pesticide registration (prospective approach) and that was not different in Brazil, a tropical country. However, methods standardized for temperate climate

may not generate realistic results in tropical conditions, since temperature, soil and ideal test organisms are different. An adaptation largely used nowadays and which turned a recommendation of standardized norms (Brazilian Association of Technical Standards - ABNT) in the country (most of them translations of ISO guidelines) is the use of the Tropical Artificial Soil - TAS, replacing the peat sphagnum for coconut fiber as source of organic matter. Another recently adopted recommendation in the norm for acute test with earthworms is the use of 25°C, instead of 20°C, although in practice, different groups all over Brazil had been using temperatures ranging from 20 to 29°C depending on the local climate. Tested substances range from herbicides, fungicides, insecticides, metals, oil, manure, sewage and others. Most studies are of prospective approach with single-species experiments trying to determine the potential impact of these substances, but pioneering studies on ecological risk assessment such as in a metal contaminated area and higher-tier tests have also been carried out. Advances and needs regarding reference natural soils, use of relevant test species, regulatory aspects and network activities will be presented and discussed.

### Elevated mobility of persistent organic pollutants in the soil of a tropical rainforest

L. Nizzetto, NIVA; Q. Zheng, Chinese Academy of Sciences Guangzhou Institute of Geochemistry; X. Liu, Guangzhou Institute of Geochemistry, Chinese Academy of Sciences / Department of Civil and Structural Engineering; K. Borga, Department of Biosciences, University of Oslo / Department of Biosciences; J. Starrfelt, NIVA; J. Li, Y. Jiang, X. Liu, Chinese Academy of Sciences Guangzhou Institute of Geochemistry; K.C. Jones, Lancaster University / Lancaster Environment Centre; G. Zhang, Guangzhou institute of Geochemistry Chinese Academy of Sciences / State Key Laboratory of Organic Geochemistry

Semi-volatile persistent organic pollutants (POP) are bioaccumulative and toxic contaminants. Their global distribution depends on source distribution, atmospheric transport, degradation and the exchange with ocean and land surface. Forests are crucial terrestrial reservoirs due to the commonly envisaged high capacity of their surface soils to store and immobilize airborne contaminants bound to soil organic matter. Here we show instead that POPs can be unexpectedly mobile in the soil of a tropical rainforest due to fast litter degradation (leading to rapid POP transfer to the sub-soil) and leaching rates exceeding degradation rates. This determines a markedly different distribution pattern with lower bulk capacity for POPs accumulation compared to soils of colder environments. Tropical forests represent 60% of the global terrestrial production expectedly playing a relevant role in POP cycling. Hence our results suggest that biogeochemistry of organic matter degradation can represent a key control on the overall contaminant fate in soil.

## Multistress in aquatic environments: the big picture (IV)

### How much do organic toxicants contribute to multiple stress in freshwater ecosystems?

R.B. Schaefer, University Koblenz Landau / Institute for Environmental Sciences; B. Kühn, Institute for Environmental Sciences University of KoblenzLandau; E. Malaj, Helmholtz Centre for Environmental Research-UFZ / Department of EffectDirected Analysis; R. Gergs, Institute for Environmental Sciences University of KoblenzLandau

Freshwater ecosystems are threatened by multiple stressors including habitat degradation, pollution and invasive species. There is a paucity of studies on the relative importance of organic toxicants for the ecological status of rivers and their co-occurrence with other stressors. We used German monitoring data to analyse the individual and joint occurrence of four stressors, namely habitat degradation, invasive species, excessive nutrients and organic toxicants. All stressors were examined for potential ecological effects based on the exceedances of low and high risk thresholds, which were based on previous studies and regulatory thresholds. At approximately 85% of the sites nutrients and habitat degradation exceeded ecological thresholds, whereas in approximately 50% of the sites the thresholds for invasive species and organic toxicants were exceeded. All sites, where data on the four stressors were available, displayed threshold exceedance from at least one stressor. Toxicity was weakly positively correlated with nutrients and habitat degradation. The risks of ecological effects from habitat degradation and invasive species were higher in lowland streams, which was particularly pronounced for invasive species. Our assessment demonstrates that habitat degradation and nutrients are dominant stressors, although we likely underestimated the risk from organic toxicants and invasive species. All sites were at risk from multiple stressors and mitigation focusing on individual stressors is unlikely to improve the ecological status. The risk of ecological effects from organic toxicants is prevalent and previous studies showed that organic toxicants may interact with other stressors in complex ways. Hence, integrating freshwater ecology and ecotoxicology is pivotal to tackle the challenge of multiple stressors.

## 587

### Modelling combined effects of exposure to metals and global warming: from individual energy budgets to ecosystem processing

N. Galic, School of Biological Sciences / School of Biological Sciences; V.E.

Forbes, University of Nebraska Lincoln / School of Biological Sciences

Freshwater ecosystems provide a number of services that are essential for human well-being, but are, at the same time, jeopardized by a range of anthropogenic activities. Changes in historical temperature regimes are exacerbated by changes in global temperatures, predicted to rise anywhere between 0.5° and 4° C by the end of the century, which is already impacting ecosystems worldwide. All these changes are predicted to have substantial effects on biotic interactions, but also on chemical toxicity. Temperature-dependency of chemical toxicity is an emerging topic of research, but has until now been focused mainly on deriving temperature-dependent ECx or assessment factors. We here present a study that integrates temperature driven sublethal effects of metals - cadmium and copper - on energy budgets of freshwater amphipods in a simulated environment where the temperature and resource dynamics are seasonal. We model the consequences for individual life histories, population dynamics and ecosystem processing. To this end, we developed an individual-based model (IBM) of a freshwater amphipod, *Gammarus pseudolimnaeus*. This amphipod is a shredder of leaf litter, and thus plays an important role in the decomposition process in freshwater ecosystems. Individual life histories are based on energy budget dynamics which are driven by external temperature, resource availability and exposure to metals. The model has been parameterized on lab and field data. We simulated a number of temperature and toxicity scenarios and compared the results to baseline simulations. Exposure profiles were assumed to be constant and at sublethal concentrations. The metal toxicity submodel was implemented as a function of temperature in two ways: hump-shaped where toxicity increases below and above an optimal temperature, and linear where toxicity steadily increases with temperature. In addition, we also modeled temperature independent metal toxicity. We show how combining independent and interactive effects of metal toxicity and warming conditions yields different predictions about possible effects on different levels - individual, population and ecosystem. The extent of these effects depended on the temperature-dependent shape of chemical toxicity and on the relative thermal changes. With our modelling approach, we are able to identify systems and scenarios potentially most at risk.

## 588

### Multistress assessment in a Mediterranean River: a field study

M. Blanco; J. RIZZI, Federal University of Paraná / Hydraulics and Sanitation; N. Colin, A. Maceda-Weiga, University of Barcelona / Department of Animal Biology; B. Wassmur, University of Gothenburg / Department of Biological and Environmental Sciences; J. Sturve, Göteborg University / Zoophysiology Dept; D. Fernandes, Institute of Environmental Assessment and Water Research IDAEACSIC; C. Porte, CSIC - IIQAB / Environmental Chemistry

The Ripoll River is a small Mediterranean river strongly affected by human pressure. Over the summer period, urban and industrial discharges arrive into the river with little dilution. In order to assess the water quality during this period, barbels -*Barbus meridionalis*- and catalan chubs -*Squalius laietanus*-, were collected from six sites, including stressed areas receiving urban and industrial waste water along the city of Sabadell, and potential reference sites, upstream the river. Hydroxylated-PAHs, nonylphenol, octylphenol and galaxolide were analysed in bile as a measure of recent exposure to these pollutants in conjunction with different biochemical responses including, 7-ethoxyresorufin-O-deethylase (EROD) and 7-benzylxy-4-trifluoromethyl-coumarin O-debenzylxylase (BFCOD). Additionally, CYP19 aromatase activity was determined in the ovaries of female barbels as a potential marker of endocrine disruption. Levels of the analysed chemicals were significantly higher in the stressed areas compared to the reference sites, which indicate that fish from the lower course of the Ripoll River are strongly impacted by anthropogenic activities. Accordingly, a significant induction of EROD (9 to 10-fold) and BFCOD (3 to 5-fold) activities were determined in both barbels and chubs. Increased CYP19 aromatase activity was detected in females collected in the stressed sites in comparison to those from reference areas. Overall, this study highlights the impact of urban and industrial effluents in common Mediterranean species from the lower course of the Ripoll River. Keywords: *Biomarkers, fish, Mediterranean rivers, pollution*

### Understanding salinity and acid mine drainage as stressors of *Caridina nilotica*

E.C. Vellemu, Rhodes University / Institute for Water Research; C.G. Palmer, Institute for Water Research; P.K. Mensah, Rhodes University / Unlever Centre for Environmental Water Quality Institute for Water Research

Salinisation of freshwater ecosystems is recognised as a global major environmental challenge. In South Africa, freshwater bodies face two fold intertwined problems: increased salinity and acid mine drainage (AMD). For over a century the country's freshwater bodies have been receiving large amounts of AMD and salts. These problems potentially threaten the country's freshwater species including macroinvertebrates such as indigenous *Caridina nilotica*. The mining industry is considered as one of the economic backbones for South Africa. However, coal and gold mining have been widely identified as the major culprits of AMD release which is associated with high sulphate and increased heavy metal concentrations. During coal mining, the rock pyrite gets fractured, oxygenated and produces sulphuric acid which makes the water highly acidic (low pH) for many aquatic species to tolerate as run off occurs. In addition, South Africa has plenty of

abandoned mining sites that decant AMD water. AMD has sharply emerged as a topical subject in recent years. Most reports in South Africa acknowledge that AMD poses negative impacts in rivers. However, there is insufficient evidence to support the risks or damages of AMD on macroinvertebrates. Although there is recommendable ongoing rivers monitoring program by the Department of Water Affairs and Sanitation, there is lack of a clear trend at spatial and temporal scales that quantifies and defines AMD in various catchment systems in the country. There is also lack of sound scientific information that establishes the interaction between salinity and acid mine drainage in water quality assessments. Therefore, this study is aimed at understanding the interaction of salinity and acid mine drainage as stressors of freshwater macroinvertebrates using *Caridina nilotica*, a common freshwater shrimp indigenous to Southern African rivers. Using chemical information and various toxicity tests, the study also seeks to establish both spatial and temporal trends of AMD occurrence in selected monitoring points in the Olifants River catchment system of Mpumalanga to institute the connection between AMD and salinity as stressors of freshwater macroinvertebrates. The findings are useful in policy formulations for water management and guidelines in the protection of freshwater macroinvertebrates to these combined stresses.

### Effects of pharmaceuticals on larvae and juveniles of *Palaemon varians* under daily variation of temperature

E. Gonzalez-Ortega; J. Blasco, Inst. Ciencias Marinas de Andalucía / Instituto de Ciencias Marinas de Andalucía; L. LeVay, L. Gimenez, School of Ocean Sciences Bangor University

The effects of pharmaceuticals are usually conducted at non-target species, evaluating a single compound at a time and at fixed environmental conditions; in addition most studies focus on one phase of the life cycle. Although the effects of emergent compounds may not significantly affect larval stages, larval experience may influence juvenile performance and the likelihood of successfully recruitment to the adult population. The objective of this study was to evaluate the effect of single vs mixture toxicity of two pharmaceuticals, Sodium diclofenac (DS) and Clofibric Acid (CA), on larval and juvenile stages of the non-target saltmarsh species *Palaemon varians*. Experiments also consider the effect of pharmaceuticals and daily variation in temperature with another pharmaceutical more, clotrimazole (CLZ), in order to test whether this compound has similar toxic effect than on *Palaemon serratus* larvae. We considered cyclic variations in temperature because larvae develop commonly in saltmarshes where water temperature may vary considerably at the daily scale. The individual exposure of DS and CA at environmental concentrations (10 and 20 µg/L) did not have any effect on survival and duration of development. The effects of these PhCs on larvae appeared with the mixture of DS and CA at intermediate doses (234 and 194 µg/L): this mixture increased the duration of development and intermoult duration required to reach the first juvenile stage. The mixture also reduced growth rates at 18°C leading to a reduction in body mass. At daily variation of temperature, the mixture of the three compounds (DS, CA and CLZ) at intermediate doses increased duration of development and at high doses also decreased larval growth rate and larval body mass. CLZ had toxic effects similar to *P. serratus* larvae: increased duration of development, decreased growth rate and larval body mass under daily variation of temperature. Some effects of pharmaceuticals appeared later during juvenile phase. This study manifested the importance to test environmental risk assessment taking into account species specific habitat conditions, the mixture of different emergent compounds and consider more than one stage on Non-target Organisms with complex life cycle. Acknowledgement - Financial support to EGO was given by Marie Curie fellowship and SCARCE (Consolider-Ingenio 2010 CSD2009-00065).

### Linking multi-pollutant stress to adverse outcomes

P. Antczak, University of Liverpool / Institute of Integrative Biology; T. Williams, University of Birmingham / School of Biosciences; M. Seibire, J. Elphinstone-Davis, Cefas; M.R. Viant, University of Birmingham / School of Biosciences; J. Chipman, The University of Birmingham / School of Biosciences; I. Katsiadaki, Cefas / Environment and Animal Health; F. Falciani, University of Liverpool / Functional Genomics

Understanding the effect of multiple stressors on aquatic organisms is vital for environmental monitoring and risk assessment. Stressors within these environmental compartments encompass perturbations in environmental factors, such as temperature, pH or oxygen saturation, and anthropogenic contaminants. Pollutants in particular are of major concern as their effect, specifically in mixtures, is largely unknown. Assessing the impact of these complex mixtures has proven to be a challenging task due to the observation of non-additive effects which may have devastating outcomes in local aquatic populations. This is only aggravated by the scarcity of toxicity information relating to chemicals shown to be present in the environment. To address these limitations, 'omics' technology has been utilized to provide an unbiased approach to measure effects of compounds and to show that the molecular state of organisms can be predictive of exposure. While these successful applications of molecular toxicity identification evaluation (mTIE) approaches have shown great potential, they generally focus on acute transcriptional response and do not provide predictive ability of chronic endpoints. Here we present a computational framework that addresses these limitations by modelling

non-additive mixture effects from acute transcriptional responses and linking those to chronic outcomes. The nature of our approach allows us to develop putative adverse outcome pathways (AOPs) which provide putative molecular initiating events (pMIE) linked through key events (KE), as observed via perturbation of pathway activity, through to measured chronic endpoints within our experimental system. We show that our approach successfully identifies key pathway perturbations linked to chronic endpoints which can be predicted via gene expression profiles derived from single chemical exposures.

## Challenges and Opportunities in Protecting Human and Ecosystem Health: Understanding the Fate, Transport, and Toxicity of Wastewater-borne Contaminants (I)

### A novel exposure model for chemicals used globally in HPC products: A Case study and evaluation

J.E. Hodges, Unilever / SEAC; J. Kilgallon, Unilever; O.R. Price, Unilever / Colworth Science Park; A. Franco, Unilever / Safety and Environmental Assurance Centre; R. Vamshi, C.M. Holmes, V. Sclater, Waterborne Environmental Inc

The global use of a range of home and personal care products is increasing. Industry has a responsibility to assess the environmental safety of chemicals used in consumer goods in all markets, not only in regions where regulations exist. Using spatially explicit data sets we present a global model, the Scenario Assembly Tool (ScenAT) to predict in-river concentrations of chemicals used in home and personal care (HPC) products. A case study has been performed estimating Predicted Environmental Concentrations (PECs) for Linear Alkylbenzene Sulphonate (LAS) calculated using a European per capita use value. Regional and country profiles of important variables (e.g. water use and sanitation practice, receiving water dilution) are explored and the impact of these variables on emission estimates and PEC distributions in major regions around the globe are illustrated and discussed. The PEC estimates for LAS are likely to be a conservative (over) estimate especially for developing areas of the globe as a European per capita usage estimate has been applied to all countries. In areas where higher PECs are forecast, further understanding into disposal practices and how products are used can be developed. Distributions will be shown for PECs, water use, dilution factors and sewage treatment connectivity for selected key countries. A preliminary evaluation exercise has been performed in China modeling the chemical ingredient Triclosan in ScenAT. On Comparison of measured concentrations and modelled urban concentrations, PECs were slightly higher than measured data (by a factor of 1.2 to 6.0). Further evaluation has been undertaken in the United States. Based on the water quality monitoring data sets available, 5 chemicals were run through the ScenAT model. The dataset showed good geographical coverage of the US and included temporal data, therefore a methodology to compare point locations (monitoring data) with polygons (ScenAT results) was created. For the majority of chemicals analysed good correlations were found between modelled and observed data. The applicability of the proposed model evaluation methodology is discussed in relation to spatial and temporal resolution of datasets. It is possible to generate improved PEC estimates at a refined spatial scale using screening level models. This allows identification of geographic locations for further investigation or more refined exposure modeling and can inform targeted monitoring campaigns.

593

### A quantitative risk ranking model to evaluate the environmental fate of "classic" and emerging contaminants in biosolid amended land and potential transport to drinking water

r.M. Clarke, University College Dublin / Biosystems Engineering; E. Cummins, University College Dublin / Biosystems Engineering

There have been concerns in recent years regarding the safety of biosolids as organic and inorganic contaminants remain in biosolids (post wastewater treatment), and can potentially infiltrate the environment following land application. The primary objective of this study was to develop a quantitative human health risk assessment model for "classic" and emerging contaminants in biosolids in Ireland. Sixteen "classic" and emerging contaminants, including surfactants (nonylphenol (NP), its short ethoxy chain precursors nonylphenol mono-(NP1EO), and di-ethoxylate (NP2EO)), perfluorooctane sulfonate (PFOS) and perfluorooctanoate (PFOA) substances, PPCPs (triclosan, triclocarban, carbamazepine), bisphenol A (BPA) and steroids (estrone and estradiol) were ranked to identify those that may pose the greatest risk to surface and drinking water and ultimately human health. A probabilistic risk assessment model was developed based on existing knowledge regarding contaminant behaviour and flow. The model was based on a comparison of the Predicted Environmental Concentration of contaminants in surface runoff ( $PEC_{runoff}$ ) to the No Observed Adverse Effects Level (NOAEL), resulting in a chemical toxicity intake Risk Ratio statistic (RR). The model used probability density distributions to characterise the uncertainty and variability in input parameters while the outputs were simulated using Monte Carlo techniques. The results of the  $PEC_{runoff}$  indicate that from the 16 contaminants analysed, the highest  $PEC_{runoff}$  value obtained was from triclocarban with a mean  $PEC_{runoff}$  value of  $3.9E+04 \mu\text{g/L}$ . The human exposure risk ranking model identified the top 5 contaminants that can be considered as priority contaminants requiring

vigilance in Ireland, these were: PFOS, PFOA, estradiol, triclocarban and BPA (with adult risk ratio values of  $3.1E-01$ ,  $7.6E-02$ ,  $1.8E-02$ ,  $1.1E-02$ ,  $8.2E-03$ , respectively). A sensitivity analysis of model inputs revealed that the soil sorption coefficient (Koc) and the soil organic carbon (SOC) were the most important parameters that affected the variance in the model predictions (Correlation coefficient values -0.61 and -0.57, respectively). The model developed in this study is of importance for risk managers in providing a ranking of potential chemical hazards resulting from the spreading of biosolids on agricultural land, while highlighting some emerging contaminants requiring vigilance in the future.

594

### Sustainability and Precautionary Principle in Source Water Protection For Drinking Water Production

I. Brünig, IAWR; A. Bannink, RIWA

From the seventies of last century the waterworks along the Rhine river in Europe (International Association of Waterworks in the Rhine basin, IAWR) have been active in the improvement of the Rhine water quality. The ultimate goal has always been a source water quality that allows the production of perfect drinking water using simple treatment only. Already in 1973 IAWR published a Rhine Memorandum stating quality demands that would help reach that goal. Interestingly, those very demands were subsequently used by the European Union as the basis of a Directive on the abstraction of surface water for drinking water production (75/440/EC). Several updates of this memorandum were published over the years. In 2013 other associations of water works also endorsed the underlying philosophy and the memorandum was broadened to the Danube-, Meuse-, Ruhr-, Elbe-, and Rhine Memorandum -European rivers which provide ground filtered water for drinking water production- representing over 170 utilities in 17 European countries, with well over 115 million consumers. The most important demands for a Source Water Protection are quality objectives for not otherwise regulated variables as groups, and demands and suggestions to (political) decision makers on the achievement of the desired water quality based on the precautionary approach.

595

### Comparison of the impact of two WWTPs discharges on PAHs in suspended particular matter (SPM) and sediment contamination in chalk streams

A. Chiffre, Laboratoire Chrono Environnement / Department of ChronoEnvironnement; A. Bolard, E. Chanez, F. Degiorgi, University of FrancheComte / Department of ChronoEnvironnement; P. Badot, University of FrancheComte CNRS / Laboratoire ChronoEnvironnement

Since 2009, several chalk streams of Northeast France, has been affected by repeated increased fish mortality and loss of macro-invertebrate diversity and density. Wastewater treatment plants (WWTPs) are considered as a major source of organic pollutants in freshwater ecosystems and could participate to the degradation of the river quality. Indeed, WWTP generally receive complex mixtures containing a wide variety of organic pollutants from domestic, industrial and storm-water sources. So they represented an important source of organic contaminants such as metals, polycyclic aromatic hydrocarbons (PAHs) and polychlorinated biphenyls (PCBs) release in the environment. Chemical contaminations were assessed in suspended particulate matter (SPM) and sediment sampled in 2 chalk streams of the Franche-Comté region (France) with a karst watershed. A small WWTP (site A) of 5000 population equivalent, and a largest (site B) of 50000 population equivalent were monitoring during a flow event. Concentrations of polycyclic aromatic hydrocarbons (PAHs) were measured in samples upstream and downstream the discharge of the both WWTPs. SPM were collected with six trap systems in each station during a flood event. PAHs diagnostic ratio was assessed to estimate the pollution emission source of SPM and sediment. Total concentration of the sixteen PAHs in SPM showed an increase downstream for both WWTPs. For site A, mean concentrations ranged from  $1524 \text{ ng g}^{-1} \text{ dm}$  upstream to  $2433 \text{ ng g}^{-1} \text{ dm}$  near downstream the WWTP. In site B SPM concentrations were higher than in site A and ranged from  $2160 \text{ ng g}^{-1} \text{ dm}$  upstream to  $4099 \text{ ng g}^{-1} \text{ dm}$  near downstream the WWTP. SPM and sediments sampled in the area with the highest anthropogenic activities were more contaminated than sampled from the rural site. The isomer ratio suggests a pyrolytic source for PAHs. The present study highlights that continuous WWTP discharges contributed to PAHs contamination from combustion source with concentration that could damage organisms.

596

### Identification and aerobic biodegradation of photo-transformation products of sulfamethoxazole

T. Su, Stockholm University / Department of Environmental Science and Analytical Chemistry ACES; H. Deng, Tongji University / College of Environmental Science and Engineering; M. Radke, Institute for Hygiene and Environment / Environmental Laboratory

The antibacterial sulfamethoxazole (SMX) is widely studied due to its ubiquitous presence in the aquatic environment and potential to induce antibiotic resistance in pathogenic bacteria. SMX can enter the aquatic environment from wastewater treatment plant or agricultural waste effluents. While photolysis and biodegradation contribute to the (relatively slow) removal of SMX in the environment, the fate and behavior of SMX transformation products (TPs) – some of which have antibacterial properties – is less well characterized. The objective of the present work was to investigate a) SMX phototransformation kinetics and product formation under

various conditions (natural versus purified waters, pH) using simulated sunlight, and b) the tendency of these photo-TPs to undergo biodegradation by sediment bacteria. The phototransformation half-life of SMX ranged from 5.2 - 32.5 hours and increased with pH. SMX tended to be more persistent in natural waters compared to acidic purified waters, likely due to a combination of radical scavenging (e.g., by nitrate), light absorption (e.g., by natural organic matters), and protonation state. Four out of the seven phototransformation products did not undergo further photolysis. Remarkably, these same TP, some of which have antibacterial properties, were also found to be recalcitrant during sediment biodegradation experiments. Also notable was an increase in SMX concentrations during biodegradation experiments, possibly indicating reformation of the parent compound from its photo-TPs by sediment bacteria. While this finding remains tentative at this time, such a process could contribute significantly to the persistence of SMX in the environment. These data highlight the importance of considering multiple transformation processes and products during the risk assessment of emerging organic contaminants.

597

#### Detection of physiological activities of pharmaceuticals in river water in Japan

M. Ihara, H. Zhang, S. Hanamoto, H. Tanaka, Kyoto University  
Over recent years, growing numbers of human pharmaceuticals have been detected in effluents of wastewater treatment plants (WWTPs) and river water. Although these are generally found at very low levels (e.g., ng/L to µg/L) in these waters, concern about their potential risks to aquatic species has been raised because they are designed to be biologically active. Before we can determine whether pharmaceuticals in aquatic environments are a threat to aquatic organisms, we must know (1) whether physiological activities, determined by mode of action (MoA), are detectable in environmental water, and, if so, (2) the extent to which aquatic organisms might be exposed to these activities. Membrane receptors act like an inbox for messages in the form of peptides, lipids, and proteins. G protein-coupled receptors (GPCRs) are the largest group of these cell surface receptors in eukaryotes, and participate in various physiological and pathophysiological processes. It is estimated that nearly half of all marketed pharmaceuticals act by binding to GPCRs: for example, antihypertensives, antipsychotics, antidepressants, antiallergenics, and antiasthmatics. In 2012, Inoue et al. developed an *in vitro* transforming growth factor- $\alpha$  (TGF $\alpha$ ) shedding assay, in which GPCR activation is measured as ectodomain shedding of a membrane-bound preform of alkaline phosphatase-tagged TGF $\alpha$  (AP-TGF $\alpha$ ) by TNF $\alpha$ -converting enzyme (TACE) and its release into conditioned medium. The TGF $\alpha$  shedding assay can detect not only activation but also inhibition of GPCRs via all four G $\alpha$ -induced signals in the same format, and is a very simple and rapid tool. In this study, we investigated the physiological activities of pharmaceuticals in a WWTP effluent in Japan, and upstream and downstream of the WWTP using the TGF $\alpha$  shedding assay. We selected receptors for angiotensin (AT1), dopamine (D2), acetylcholine (M1), histamine (H1), and so on, and investigated (1) whether GPCR was activated or inhibited by wastewater and river water extracts, and (2) whether the WWTP effluent affect the physiological activities of pharmaceuticals in river water.

### Innovations in environmental analytical chemistry: the quest for pollutants using target and non-target approaches (IV)

598

#### Analytical and chemometric tools for the comprehensive study of complex environmental matrices by High-Resolution Mass Spectrometry

A. KISS, Institut des Sciences Analytiques / TRACES Team; A. Gonzales, S. Baig, Degremont; E. Vulliet, CNRS

Due to recent technological advancements, the comprehensive (non-target) analysis of complex environmental matrices is now a high potential strategy characterised by robustness and high throughput. This growing strategy is now recognized as a promising analytical field for various types of environmental chemistry and human health studies. In this context, we chose to illustrate a complete workflow for the interpretation of molecular prints with a special emphasis on the contribution of high resolution mass spectrometry (HRMS). The results presented here are issued from the study of an integrated water treatment system combining biological and chemical oxidation. Thus, the aim of our study is to develop an analytical methodology based on comprehensive molecular prints in order to (i) identify and prioritize emerging contaminants and (ii) to contribute to the assessment of the performance. This analytical strategy was implemented on a LC-QqTOF instrument and consisted in two main steps: (i) a target and non-target screening for compounds and their transformation (degradation) products (*monoisotopic exact mass, isotopic profile and mass defect*) and (ii) a comprehensive study based on the comparison of 2D molecular prints (*m/z*, retention time) by *multivariate chemometric approaches* such as Principal Component Analysis. In order to illustrate the strengths and the limitations of mass spectrometry for the annotation and identification of small molecules, we will thoroughly discuss specific notions based on practical examples obtained during this study (resolution, precision, the exact monoisotopic mass, mass defect and isotopic profile, fragmentation). The main challenges regarding the quality of the molecular prints (i.e. acquisition and data analysis parameters) will be also emphasised during this talk. The comprehensive approach applied in this study led to information-rich molecular

prints which *successfully complement* the previous target study by offering a broader view of the samples. The use of separation techniques coupled to high resolution mass spectrometry is fully justified by (i) the high number of detected signals, (ii) the wide dynamic range, (iii) the diversity of physicochemical properties, (iv) the presence of isomers and (v) the need for an additional dimension in order to discriminate the signals having similar *m/z* ratios.

#### Prediction of pharmaceutical and illicit drug residue retention times in wastewater extract data acquired by gradient liquid chromatography-high resolution mass spectrometry

L. Barron, Kings College London / Analytical and Environmental Science; K. Munro, Analytical and Environmental Science; T.H. Miller, Kings College London / Analytical and Environmental Sciences; C.P. Martins, A. Edge, Thermo Fisher Scientific; D.A. Cowan, Kings College London / Drug Control Centre  
The application of *in silico* tools for post-data acquisition mining of liquid chromatography-high resolution mass spectrometry (LC-HRMS) data holds potential to more rapidly identify novel or emerging pollutants. Data-mining tools are currently available for mass screening of complex HRMS data, but suspect confirmation still requires a matching chromatographic retention time (*t<sub>R</sub>*) with a reference standard, which are often prohibitively expensive, limited or require synthesis *ab initio*. Even with HRMS technology, several viable chromatographic peaks at isobaric *m/z* may exist in environmental samples, which makes selection of reference materials for synthesis even more challenging. Currently, appropriate *t<sub>R</sub>* prediction tools for small ionisable molecules such as pharmaceuticals, personal care products and illicit drugs in complex samples are lacking. Herein, the development, characterisation and application of an accurate neural network (ANN) for prediction of gradient reversed-phase liquid chromatographic retention times (*t<sub>R</sub>*) for 166 pharmaceuticals in wastewater extracts is presented for the first time and coupled with qualitative HRMS data mining methods. Multiple ANN architectures including radial basis function (RBF), multilayer perceptron (MLP) and generalised regression neural network (GRNN) were investigated and a comparison of their predictive ability for model solutions discussed. The influence of wastewater matrix complexity on *t<sub>R</sub>* showed a variance of >1 min for some compounds in comparison to model solutions. Similarly, matrix impact on ANN predictive ability was addressed towards developing a more robust approach for routine data screening applications. Overall, the optimised GRNN-type model had a predictive accuracy of < 1.3 min at the 75<sup>th</sup> percentile of all measured *t<sub>R</sub>* data in wastewater samples (2=0.92). Finally, the model was evaluated for application to the semi-targeted identification of pharmaceutical residues during a weeklong wastewater sampling campaign. The model successfully identified native compounds from an HRMS database shortlist (from >1,500 compounds) at a rate of 82±5 % and 74±5 % in influent and effluent extracts respectively. Ultimately, this research will potentially enable faster identification of emerging contaminants in the environment through more efficient post-acquisition data mining

#### Sensors for in-situ monitoring of Eutrophication

M. McCaul, National Centre for Sensing Research / National Centre for Sensing Research; J. Cleary, Carlow Institute of Technology; E. McNamara, D. Diamond, Dublin City University / National Centre for Sensing Research  
This work is carried out as part of the COMMON SENSE European FP7 project. The COMMON SENSE project aims to provide a reliable sensing platform for in-situ measurements on key marine water quality parameters relating to eutrophication, heavy metal contaminants, marine litter and underwater noise. The COMMON SENSE nutrient sensor is based on a combination of microfluidic analytical systems, colorimetric reagent chemistry, low-cost LED-based optical detection, and wireless communications. The reliable quantification of nutrients in marine environments is challenging due to the low concentration of these solutes in the ocean and the nature of the matrix in which they are held. Initial studies are focused on validating a method for the sequential determination of nitrite and nitrate in marine environments. Coupled with the traditional well established Griess-Ilosvay reaction for the determination of nitrite, a vanadium chloride (VCl3) solution is used as the reducing agent. The method shows potential as an alternative to the toxic cadmium column for the reduction of NO3- to NO2- in marine water as results indicate that there is no apparent interference from variances in background salinity. The method was tested on a series of samples with varying salinities and sample matrices (costal, estuarine and freshwater), the method is low cost, reproducible and requires low volumes of sample and reagents.

#### Using UV LEDs to Limit Biofilm Formation with Applications for Optical Sensors

K. Murphy, Dublin City University / NCSR; A. Barrett, Dublin City University / Department of Chemical Sciences; T. Sullivan; J. Moreno, Dublin City University / Department of Chemical Sciences; f. Regan, Dublin City University / Chemical Sciences  
Biofouling is a serious, longstanding issue for optical detection systems working in aquatic environments. UV radiation has long been known as having a germicidal and biocidal effect, particularly in the UV-C regime. This effect has been used for applications such as water sterilisation and food safety. It has also garnered interest

among researchers of environmental sensing as an anti-foulant, or as an aid to it, in particular for optical sensors. The increase in the volume of sensors means that the cost of ownership of sensors needs to be addressed, making biofouling abatement a key issue. Traditionally, logistical and cost reasons prevented the use of UV light on optical surfaces underwater, with broadband UV lamps being unsuitable and impractical for use with individual optical sensors. Recent advances in UV LED technology mean shortly it should be possible to treat small surfaces areas effectively. Some investigations have taken place of late, focusing on water disinfection, into the use UV LEDs, of distinct wavelengths, for germicidal purposes. Harnessing the germicidal and biocidal effects of UV radiation using LEDs could lead to a cost- and power-effective method for anti-fouling with *in-situ* sensors for aquatic environments. In this abstract we present early results of biofilm growth abatement on polymer surfaces with UV LED radiation treatment, in a laboratory environment conducive to the growth of biofilms. Commercially available, competitively priced LEDs are utilised in this work (UVTOP UV-LEDs). These LEDs have a peak wavelength of 285nm, a FWHM of 12 nm and an optical power at 20mA of 0.8mW. A water bath incubator is seeded with *Chlorella Vulgaris* algae and PDMS coupons are placed into it, with some illuminated by the UV LED and some unexposed as control coupons. The exposed coupon is covered and so is unaffected by ambient light. The control coupons are subject to ambient light conditions. Using this setup a number of trials were carried out, with the level of biofilm growth on the coupons quantified using epifluorescence microscopy and a cell counting image analysis program. Initial results from a test series, of one test and one control coupon each split into four quadrants, are presented here. The results show a 62% reduction in cell numbers in the centre of the coupons, where the majority of the UV is concentrated but fades away towards the edge of the coupon.

602

#### Development of an indirect enzyme-linked immunosorbent assay for the detection of sulfonamides in seawater

C. Bosch, IDAEA-CSIC; J. Salvador, P. Marco, Institut Català de Nanociència i Nanotecnologia ICN CSIC CIBERBBN; M. Farre, IDAEA-CSIC; D. Barcelo, IIQAB-CSIC / Institute for Environmental Assessment and Water Research Aquaculture has increased and intensified during last decades all over the world. The widespread of these activities have displayed some other inconvenients as the case of the antibiotics abuse. Although these compounds are very efficient to treat bacterial diseases in the marine organisms, are also used in prophylactic therapy and for growth promotion, causing their propagation along the aquatic environment as well as along the food chain. Moreover, it has been demonstrated that antibiotics promote the bacterial acquired resistance even at low concentration levels. Sulfonamides (SAs) are a large group of antibiotics widely used in aquaculture. Seven of the most frequently used SAs have been studied in this work - sulfadiazine (SDZ), sulfathiazole (STZ), sulfapyridine (SPY), sulfadimethazine (SDZ), sulfamethoxy-pyridazine (SMP) and sulfaquinoxaline (SQ). A competitive indirect enzyme-linked immunosorbent assay (ELISA) has been developed to determine the presence of these compounds in seawater. The results obtained will be used to develop a biosensor based on immunosensor system in the frame of the Sea-on-a-CHIP project. The optimal concentrations of the immunoreagents were set by double checkerboard experiments, selecting those which absorbance values were near the unit. Concentrations were reached through successive serial dilutions in relation 1/2 ranging from 1 µg/mL of SA2-BSA and ranging from 1/1000 of As155. The optimal concentration was 0.25 µg/mL for SA2-BSA and the dilution of 1/8000 for As155. The limit of detection (LOD) for the method (IC<sub>90</sub>) was 0.060 ± 0.041 µg/mL. IC<sub>50</sub> (concentration corresponding to the 50% of the maximum signal) was 1.051 ± 0.384 µg/L (4.182 ± 1.712 nM). The assay showed good performance as class immunoassay for the most commonly used sulfamides antibiotics in veterinary medicine; the 7 compounds can be recognised as demonstrated the cross reactivity assays, while not significant matrix effects were observed using seawater instead of phosphate buffers.

603

#### Pesticides in seawater: method development & fate in Catalonia coastal areas (NE-Spain).

M. Köck-Schulmeyer, Water and Soil Quality Research Group Dept of Environmental Chemistry; M. López de Alda, Institute of Environmental Assessment and Water Research IDAEA CSIC / Environmental Chemistry; M. Farre, IDAEA-CSIC; D. Barcelo, IIQAB-CSIC / Institute for Environmental Assessment and Water Research Anthropogenic activities in coastal areas lead to loss of species and populations, physical damage to marine habitats and chemical pollution, littering to the sea, and introduction of non-indigenous species. Among the different pollutants, the group of endocrine disrupting chemicals, which is an extensive and heterogeneous group of substances that may interfere with the endocrine system and hormone activities of organisms, is especially relevant. Within this category, pesticides stand out for being chemicals extensively used in both agricultural and urban areas, reaching environmental waters through diverse processes. In this context, the main goals of this study were the optimization and validation of an analytical approach suitable for the assessment of multiple pesticides (more than 30, including some transformation products) in seawater, based on solid phase extraction (SPE) followed by liquid chromatography-electrospray-tandem mass spectrometry

(LC-MS/MS), and its application in the analysis of different coastal seawater (40 samples) collected along the Catalan coast. This goal is under consideration in the **SEA-on-a-CHIP project** (which aims to develop new analytical approaches and a miniaturized, autonomous, remote operated sensor system able to analyse organic contaminants affecting or/and produced by aquaculture in marine waters under multi-stressor conditions) and the **Solutions project** (which aims to develop tools for the identification, prioritization and assessment of those water contaminants that may pose a risk to ecosystems and human health). The method developed showed satisfactory performance in the analysis of the target pesticides in both HPLC water and seawater. The analytical method presented recovery rates (calculated after blank subtraction) between 70 and 120% relative to the corresponding deuterated standards in most cases. In addition, good sensitivity with method limits of detection (MLOD) in the ng/L range or lower was achieved in real seawater samples. Satisfactory linearity and repeatability (with relative standard deviations below 20% in the most of the cases) were also obtained. In the present study, concentrations at ng/L levels of several of the target compounds were found, in agreement with the results of previously published studies. In addition, hot spots related to pesticides contamination along the Catalan coast were identified. The potential sources of contamination by pesticides are also hypothesized and discussed.

## Challenges in Wastewater Treatment and Reuse and the Agricultural Use of Manures and Biosolids (III)

#### Impacts of metals on antibiotic resistance and conjugal plasmid transfer in soil bacterial communities

K.K. Brandt, University of Copenhagen / Department of Plant and Environmental Sciences; U. Klümper, Technical University of Denmark / Department of Environmental Engineering; W. Luo, University of Copenhagen / Department of Biology; J. Song, University of Copenhagen / Department of Plant and Environmental Sciences; T.A. Johnson, Michigan State University / Center for Microbial Ecology Department of Civil and Environmental Engineering; J.J. Modrzyński, University of Copenhagen / Department of Plant and Environmental Sciences; L. Riber, University of Copenhagen / Department of Biology; M.H. Nicolaisen, University of Copenhagen / Department of Plant and Environmental Sciences; L.H. Hansen, Aarhus University / Department of Environmental Science; J. Jensen, Aarhus University, DMU / Department of Bioscience; A. Dechesne, Technical University of Denmark / Department of Environmental Engineering; S.A. Hashsham, Michigan State University / Center for Microbial Ecology; P.E. Holm, University of Copenhagen / Department of Plant and Environmental Sciences; B. Elberling, University of Copenhagen / Center for Permafrost; J.M. Tiedje, Michigan State University / Center for Microbial Ecology Department of Civil and Environmental Engineering; O. Nybroe, University of Copenhagen; B.F. Smets, Technical University of Denmark / Department of Environmental Engineering; S.J. Sørensen, University of Copenhagen / Department of Biology Environmental selection and horizontal gene transfer constitute key processes in the environmental development and spread of antibiotic resistance. We previously demonstrated that long-term (+85 years) exposure to Cu had co-selected for antibiotic resistance in a soil receiving no known anthropogenic inputs of antibiotics. Here, we extend our previous work on metal-induced selection pressures for the expansion of the soil bacterial resistome by studying the co-selection phenomenon and its underlying mechanisms in more detail. Phenotypic antibiotic resistance profiling was performed at the community level using the pollution-induced community tolerance (PICKT) approach complemented by phenotypic resistance plating of soil bacterial isolates. Antibiotic resistance genes were enumerated using a high-capacity quantitative PCR array against DNA extracted from soil. Plasmid prevalence was determined in a large set of soil bacterial isolates and plasmid DNA from selected isolates was sequenced (Illumina MiSeq). Effects of metal stress (Cu, Zn, Ni, Cd, As) on the permissiveness of soil bacteria to take up the broad host range plasmid pKJK5 was studied using a recently developed cultivation-independent approach employing high-throughput fluorescence activated cell sorting allowing sorted transconjugants to be identified by 16S rRNA gene amplicon pyrosequencing. Our results suggest that the potential for metal-induced co-selection is a general phenomenon for bacterial communities present in Danish agricultural soils, but not for 'pristine' permafrost bacterial communities. However, co-selection of antibiotic resistance is difficult to predict due to spatial heterogeneity and requires higher Cu levels than required for development of Cu resistance. The detection of a novel plasmid carrying two copper resistance gene clusters along with various efflux pump encoding genes likely to be involved in antibiotic resistance suggest co-resistance as a likely co-selection mechanism in polluted soils, but such mobile genetic elements may be missing in permafrost containing 'pre-antibiotic era' bacterial communities. We also demonstrate that a large fraction of the soil bacterial community can take up the broad host range plasmid pKJK5. However, metal stress changes the plasmid transfer ability suggesting that this should be considered when applying metals to fields through agricultural practices.

#### Silver tolerance and resistance in environmental microbial communities:

## Implications for human health

E. Donner, S. Vasileiadis, E. Lombi, University of South Australia / Centre for Environmental Risk Assessment and Remediation; S. Wakelin, AgResearch; G. Kowalchuk, Utrecht University

Silver-induced selective pressure on environmental bacterial communities is becoming increasingly relevant due to the growing use of silver nanoparticles (Ag-NPs) as antimicrobial agents in biomedical supplies and other commercial products. Genetic silver resistance in Bacteria is known to exist, and it is possible that horizontal gene transfer mechanisms, such as those involving intermediate to broad host range conjugative plasmids (e.g. IncH and IncP groups) [1], may facilitate the transfer of resistance among bacterial community members in densely populated environments. We conducted several different studies to investigate the effects of significant silver selective pressure on environmental microbial communities. In one study, 5 Australian soils with a broad range of physico-chemical properties were exposed to silver for 2 weeks (2W or fresh) or 9 months (9M or aged) at concentrations ranging from 50–400 mg/kg Ag, while unspiked soils were maintained as controls. Total DNA was extracted from the soils in triplicates and polymerase chain reaction (PCR) based counting (real-time quantitative PCR) and partial sequencing (Illumina MiSeq platform based) of the 16S rRNA gene of Bacteria in 100 samples was performed for bacterial diversity studies. In a second study, 10 different soils were exposed to 9 concentrations of Ag<sup>+</sup> ranging from 1 – 2000 mg/kg to ensure full dose-response curves could be obtained. After a two month incubation, analysis included 6S rRNA partial sequencing for phylogenetics, quantification of key genes by real time-PCR, high-throughput soil respiration by MicroResp, and a suite of 8 different enzymatic activities. Silver resistance was also tested in wastewater samples from the Adelaide treatment and reuse schemes. Collectively, our results show that the effects of silver on total environmental microbial communities depend on the pre-exposed communities, and that potentially silver-resistant pathogenic strains can be found in environmental samples.

606

### In situ microbial resistance to sulphonamides: quantification and fate of sulphonamide consumption in the Llobregat river.

R. Gioia, Cefas; M. Costa, CSIC-IDAEA; J. Aceña, IDAEA-CSIC; S. Perez, IDAEA-CSIC / Environmental Chemistry; D. Barcelo, IQAB-CSIC / Institute for Environmental Assessment and Water Research; E.O. Casamayor, CEAB-CSIC; J. Dachs, IDAEA-CSIC / Environmental Chemistry

The occurrence and spread of antibiotic-resistant bacteria (ARB) are pressing public health problems worldwide, and aquatic ecosystems are a recognized reservoir for ARB and antibiotic resistance genes (ARGs). In order to assess the role of ARB in affecting antibiotic concentrations (sulfamethazine and sulfamethoxazole) in freshwaters, and vice versa, we collected river water and cobbles at the source of the Llobregat river (Spain, upstream, pristine waters) and at the mouth of the Llobregat river (NE Iberian Peninsula, downstream, polluted waters). The activity of the benthic microbial biofilms attached to rocks (epilithic) was investigated in response to chemical concentration of antibiotic sulphonamides. The experiment lasted for approximately 60 days (July–September 2012). We observed a decrease of sulfonamide antibiotics concentrations within 2 days in both pristine and polluted waters, and the production of different transformation products concomitant with a steady increase of ARG in the epilithic biofilm community. However, the two ARG tested (SULF1 and SULF2) showed different patterns. Results suggest higher effects after high additions of antibiotics, although in all mesocosms the communities were fully recovered after 30 days. The microbial biofilm act as “natural treatment systems”, resulting in decreased chemical concentrations of antibiotics.

607

### Definition of limits of detection and quantification of antibiotic resistance genes in soils: a first step on the assessment of the impact of wastewater irrigation

S. Teixeira, Faculdade de Engenharia - Universidade do Porto / LEPABE Laboratório de Engenharia de Processos Ambiente Biotecnologia e Energia; C. Becerra-Castro, CBQF - UCP / CBQF Centro de Biotecnologia e Química Fina; C.M. Manaia, CBQF Centro de Biotecnologia e Química Fina; O.C. Nunes, Faculdade de Engenharia - Universidade do Porto / LEPABE Laboratório de Engenharia de Processos Ambiente Biotecnologia e Energia

The spread of antibiotic resistance is considered an environmental problem worldwide that represent a serious threat to public health. Wastewater is known to be an important source that contribute to this dissemination. Therefore, the use of treated wastewater for irrigation could introduce antibiotic resistant bacteria and genes into soils. However, the correct assessment of the implications of wastewater irrigation will be limited by the minimal dose of genes or bacteria cells in soils that can be detected and quantified. In this study, we aimed at assessing the PCR and qPCR detection and quantification limit of antibiotic resistance genes in an agricultural soil. With that purpose, were settled microcosm assays, in which an agricultural soil was soaked with a synthetic effluent inoculated with two antibiotic resistant isolates from wastewater. Antibiotic resistant strains *Escherichia coli* A2FCC14, which harbours the genes *bla*TEM, *bla*CTX-M-15, *bla*OXA-1, *aac*(6)-Ib-cr and the integrase *Int*I-1, and *Enterococcus faecalis* H1EV10, with the gene *vanA*, were inoculated in agricultural soil at densities ranging from

approximately 10<sup>2</sup> to 10<sup>9</sup> CFU g<sup>-1</sup> soil. A control was prepared using the same synthetic effluent without bacteria. Serial dilutions of soil samples were plated on m-Faecal Coliforms agar and on m-Enterococcus agar for enumeration of coliforms and enterococci, respectively. Bacteria growing on these culture media were compared with originally inoculated strains based on RAPD profiling. For gene detection and quantification, total DNA was extracted from soil with Power Soil™ DNA Isolation Kit (MO BIO) and PCR amplification was performed for each treatment targeting the abovementioned genes. The limit of detection by conventional PCR for the *bla*TEM and *vanA* genes corresponded to bacterial densities higher than 10<sup>5</sup> CFU g<sup>-1</sup> soil. These results and other conventional and qPCR estimations will be discussed, emphasizing the importance of defining the detection and quantification limits when the fate of antibiotic resistance genes in soils irrigated with wastewater is under analysis.

Keywords: antibiotic resistance, soil, wastewater

Acknowledgments: This study was carried out under the scope of the COST Action ES1403 –NEREUS and financed by FCT (PEst-OE/EQB/LA0016/2013, PEst-C/EQB/UI0511/2013) and FEDER through “Programa Operacional do Norte-ON2” (LEPAE/CEFT – reinforcing R&D engineering competences in Energy, Environment & Health)

### Establishing causality in ecotoxicological risk assessment of micropollutants in wastewater effluents

A. Tlili, Eawag / Environmental Toxicology; R. Behra, Eawag / Department of Environmental Toxicology

Micropollutants (MPs) released into fresh waters via wastewater treatment plants (WWTPs) are recognized as a global problem contributing to the degradation of ecosystem quality. Therefore, the aim of this field study is to causally link real effects resulting from microbial community-level exposure to complex mixture of MPs present in WWTPs effluents. To achieve this goal, we combined time-integrative passive sampling technologies with the assessment of extract toxicity via bioassays; using in-situ sampled periphyton. Periphyton were sampled up- and downstream of four WWTPs effluents in Switzerland and exposed to various dilutions of extracts from passive samplers that were immersed at the effluent of each site. Tolerance of communities to Chemcatcher® passive sampler extracts was determined according to the pollution-induced community tolerance (PICT) concept by measuring the inhibition of various functional endpoints. Specific tolerance of the heterotrophic component of periphyton was measured by <sup>14</sup>C-leucine incorporation and MicroResp™ method to measure secondary production and heterotrophic respiration, respectively. Specific tolerance of the phototrophic component of periphyton was assessed by <sup>14</sup>C-carbonate assimilation and algal fluorescence to measure primary production and photosynthetic yield, respectively. Additionally, we examined shifts in the structure of up- and downstream periphyton by performing a community level physiological profile (CLPP) and a DNA fingerprint analysis. Results showed that despite low concentrations of MPs detected downstream of the effluents, phototrophic and heterotrophic components of the sampled periphyton displayed increased tolerance towards these MPs. Interestingly, in comparison to heterotrophic functional endpoints, tolerance increase of phototrophic endpoints was variable among sites. These findings might give a first indication on the MPs composition in the effluents (dominance of herbicides or bactericides), which was confirmed by analytical identification of MPs in the passive samplers' extracts. The observed effects were accompanied by changes in the microbial CLPP and in molecular diversity. Overall, our study highlights the sensitivity of the proposed approach to detect effects of low MPs concentrations occurring in the field and to establish a causal link between exposure and the observed ecological effects on freshwater microbial communities.

609

### Real-time and in situ monitoring of aquatic environments using indigenous microbial community-based biosensors

J. Monier, O. Sibourg, ENOVO

Increasing contamination of aquatic environments by organic loads or toxic chemicals has resulted in the need for real-time monitoring tools to be used in pollution detection and risk assessment. While monitoring aquatic environments is critical to ensure their quality and sustainability, monitoring strategies often relies on the collection of individual spot samples followed by *ex situ* analyses under laboratory conditions. Such approach, usually costly and time-consuming, only provides a snapshot that may often fail to detect localized transient contamination events and describe the dynamic changes of the monitored environment. The objective of our work was to develop a cost-effective event detection system to monitor aquatic environment in real-time, inform targeted sampling by conventional means (ie spot sampling) and act as a decision support tool. This novel biosensor uses microorganisms naturally occurring in the targeted environment as bioindicators and exploits their ability to convert chemical energy into an exploitable electrical signal. The electrical signal generated by the sensor is proportional to the organic load or affected by the presence of toxic compounds, as it directly reflects microbial activity at the surface of the colonized electrodes. Biosensors have been deployed at different sites in order to estimate either the organic load or BOD in real time (eg, sewage networks, wastewater treatment plants, groundwater...) or detect toxic compounds and assess their impact on their environmental sink (eg, industrial processes and wastewater treatment plants...).

Through real case studies, the presentation will address the principle, information provided and advantages (*in situ*, autonomy, robustness, representativeness, sensitivity) of such devices and how they can provide unique information to act as a decision support tool (eg, targeted sampling, process optimization, process dysfunction identification, bioremediation treatment efficiency...). Work in progress regarding a metrological station that uses a combination of different monitoring devices developed to manage urban water in real time will also be presented.

## Emerging Contaminants in the Marine Environment: Presence, Effects, Regulation (I)

### 610

#### Marine monitoring campaign in France and French overseas departments: more than 10 000 datasets from grab and passive sampling

F. Botta, INERIS; A. Abarnou, G. Bocquené, M. CHAMPIN, G. Durand, J. Gonzalez, J. Masson, P. Priou, C. Tixier, M. LeMoigne, IFREMER; N. Tapie, ISM/LPTC - UMR5255 CNRS; F. Lestremay, S. ANDRES, INERIS; M. Dévier, LPTC-EPOC, University of Bordeaux / Oceanic and Continental Environments and Paleoenvirons; P. Labadie, University of Bordeaux / UMR EPOC Equipe LPTC; e. vuillet, ISA; D. Amouroux, LCABIE IPREM / UMR CNRS; M. Montperrus, Université de Pau; H. Budzinski, University of Bordeaux / UMR EPOC Equipe LPTC; V. Dulio, INERIS

A screening study of emerging contaminants was carried out in 2012 in coastal waters in both metropolitan France and overseas departments (Martinique, Guadeloupe, Reunion, Mayotte and French Guiana) as part of the National Action Plan against pollution of the aquatic environment, which requires the regular updating of the lists of substances to be included in monitoring programmes. The Action Plan stresses the need to set up a watch list of substances to be investigated at the national level in order to acquire missing information about the level of exposure to emerging contaminants in the aquatic environment and allow identification of substances for which specific actions need to be implemented. The Ministry of Ecology appointed ONEMA as principal contractor and INERIS as project leader. One of the main objectives of this screening study was to gain knowledge of the occurrence of substances of “emerging” concern in the marine environment. Different data were collected, such as the presence/absence of each investigated compound and the level of concentration observed in the aquatic environment (water and sediment). Moreover, the performance of different sampling techniques was assessed. This study contributes to increased knowledge of emerging pollutants in French waters and to the wider considerations for updating the list of relevant substances to be included in the new monitoring programmes to be established. Triplicate sampling of water at the same site followed by SBSE extraction displayed a high results variability, which limits the exploitation of the quantified results. Nevertheless, the testing of *in situ* systems integrators – POCIS – and extraction by SBSE bars has proven the added value of these two complementary techniques for monitoring hydrophobic and hydrophilic compounds in marine water. Finally, analyses of sediment allowed a more complete assessment of the quality of the waterbodies.

### 611

#### Marine monitoring shows emerging long-chained perfluorinated compounds in biota, following the ban of PFOS.

M. Haave, Uni Research, SAM-Marin / Uni Research Environment; K.S. Hatlen, Uni Research, SAM-Marin / Environment

Perfluorinated Alkylated Substances (PFAS) containing perfluorooctanyl sulphate (PFOS) and perfluorooctanoic acid (PFOA) were used in firefighting foams in Norway up to 2005, but were banned due to their persistent, bioaccumulating and toxic properties (PBT). PFOS was replaced with 6:2 fluorotelomersulfonate (6:2FTS) as well as several long-chained PFAS (C9-C14) that would not degrade to PFOS/PFOA. 6:2FTS was considered a safe, non-PBT alternative. Samples from sediment and biota taken from 2010-2013 near petroleum processing plants (gas- plants, refineries, crude-oil terminal) in Western Norway provide data on temporal and spatial trends, including PFUnA and PFTrA that have recently been listed by ECHA as substances of very high concern (SVHC). Sediment, limpets (*Patella vulgata*), common crabs (*Cancer pagurus*) and coastal cod (*Gadus morhua*) were collected during routine monitoring. Sediment (three sites), Limpets (all sites), crab claw-meat (Mongstad refinery, 2013), and cod liver (Kollsnes gas-processing plant, 2010-2013) were collected and analyzed for 22PFAC by an accredited laboratory. PFC levels are low in sediment at all sampled sites. Concentrations in limpets reflect recent and on-going discharge, and include 6:2FTS. FTS levels drop quickly with distance from source, and time. Limpets at reference sites show increasing C9-C13 PFAS during 2010-2013, while PFOS levels decrease. In crabs, the main PFCs are PFOSA, PFTrA and PFTA (34, 28 and 9%, respectively). In cod liver, PFOS and PFDoA dominate (Fig 2A). PFOS in cod decrease from 2011 to 2013, while PFDoA increase to max 32% of ?PFC (mean24 and 15% in 2012 and 2013 respectively). Mean and maximum ?PFC22 in cod liver increases from 2010 to 2013 (Figure 2B), and long chain PFCs, such as PFUnA and PFTrA are emerging PFCs in several types of biota. 6:2 FTS was found in 2011 in cod-liver near the plant, but not at the reference site, and in 2013 FTS was not present in cod. 6:2FTS is also transient in limpets. The findings support that FTS is

not persistent or bioaccumulating, but that C9-C14 PFCs spread and bioaccumulate in limpets, edible crabs and cod liver, far from known sources of PFC. Diffuse sources may exist. PFAS, chain length C15-C18 are not routinely analyzed in marine monitoring, and their presence is so far unknown. Mean PFOS levels are below Predicted No effect Concentrations (PNEC) in biota and EFSA's Tolerable Daily Intake (TDI) at all sites. Continued monitoring is advised.

### 612

#### Occurrence and fate of endogenous steroid hormones, alkylphenol ethoxylates, bisphenol A and phthalates in Pearl River Delta, China

Q. Wu; C. Lam, X. Zhang, City University of Hong Kong; X. Guo, Shenzhen Oceanography and Fishery Environment Monitoring Station; K. Lam, City University of Hong Kong

The endocrine disrupting chemicals (EDCs) have attracted strong scientific interest for causing hazard effect on aquatic organisms. The occurrence, distribution and potential risk of highly concerned alkylphenol ethoxylates (APEOs), bisphenol A (BPA) and phthalic acid esters (PAEs) in Pearl River Delta (PRD), the “world factory”, were investigated in this study. Natural estrogens, especially estrone, were found with higher concentration level and detect frequency, while the synthetic estrogen 17 $\alpha$ -ethynylestradiol, Diethylstilbestrol and equilenin were sporadically detected. For progesterone and androgen, norethindrone, progesterone and testosterone were detected at low concentration levels. Nonylphenol-n-ethoxylates (n=0-2) were significantly higher than 4-tert-octylpheno-n-ethoxylate (n=0-2), but still lower than the level from other countries. Bisphenol A concentrations were almost within the same order of magnitude from these studies all over the world, suggesting their gradually converged worldwide usage. Dimethyl phthalate (DMP), diethyl phthalate (DEP), di-n-butyl phthalate (DNBP), di-iso-butyl phthalate (DIBP), bis(2-ethylhexyl) phthalate (DEHP) were the most frequently detected PAEs, but with obvious spatial distribution diversity. The concentrations of DMP in river water were significant higher than that in Shenzhen coast area, nevertheless, the concentrations of DIBP in coast seawater was predominated and were much higher than that in river samples. The composition profiles and concentration levels of the target compounds between the surface and bottom water in the same sampling location were similar, which indicated the rapid vertical diffusion. The average distribution coefficient ( $K_d$ ) showed positive correlation with the octane-water partition coefficients ( $K_{ow}$ ) in logarithm for compounds in PAE group, while that in other two groups didn't own the correlation. A preliminary risk assessment was quantitated by risk quotient (RQ). The result showed that APEOs and PAEs had less potential to cause adverse effect to the local species (RQ<0.1), however the steroid hormones, E2 and EE2, had higher risk for causing estrogenic effects to the marine organisms at several sampling points in the west of Shenzhen coastal (RQ>1). Therefore, it's necessary to give high priority in further reducing the level of steroid hormone in PRD region in consider of their high estrogenic activity.

#### Field Validation of an Integrative Passive Sampler for Munitions Constituents in Marine Environments

G.H. Rosen, SPAWAR Systems Center / Energy and Environmental Sustainability; G.R. Lotufo, U. S. Army ERDC / Environmental Laboratory; J.B. Belden, Oklahoma State University / Department of Zoology; R.D. George, US Navy, Spawar Systems Center 2361; V.J. Kirtay, SPAWARSYSCEN SAN DIEGO / Energy and Environmental Sustainability; B. Wild, SPAWAR Systems Center Pacific

The measurement of trace level polar organic compounds in environmental matrices represents a significant challenge. Recent improvements in analytical techniques coupled with the development of passive sampling devices (PSDs) have much to offer towards *in situ* monitoring of ultra-low concentrations of legacy and emerging contaminants by providing time-integrated samples, including use of Polar Organic Chemical Integrative Samplers (POCIS). We expanded the use of POCIS to include energetic materials such as trinitrotoluene (TNT), degradation products of TNT (e.g. aminodinitrotoluenes [ADNTs] and diaminonitrotoluenes [DANTS]), and trinitrohexahydro-s-triazine (RDX), due to their prevalence in military munitions worldwide, and regulatory and public concern associated with their potential for exposure to marine environments. The POCIS were first calibrated for the above MC in laboratory based experiments which showed that the commercially available pharmaceutical HLB formulation was optimal, that the samplers were integrative for at least 14 d for all of the above under constant conditions, and provided sampling rates ( $R_s$ ) between 34-215 ml/, in the range reported for other polar organics. Fluctuation of MC concentrations (averaging ~0.43  $\mu$ g/L for each analyte) over a 28-day exposure indicated that wildly fluctuating, moderately fluctuating, and constant exposure concentrations resulted in statistically similar sampling rates, verifying that POCIS were integrative across multiple anticipated exposure conditions. A controlled field validation using Composition B (39.5% TNT, 59.5% RDX, 1% wax binder) as a positive control and point source was conducted in Santa Rosa Sound, Florida, FL. The results of this field effort indicated that water concentrations, expressed as POCIS-derived TWA concentrations ranged from 11-218 ng/L for TNT and RDX outside the source canister, with concentrations rapidly decreased with increasing distance from the source to below detection at 5m. The controlled field study verified the utility of the POCIS for MC in marine environments. Our study team will summarize the above

calibration and field validation results, and also discuss initial results associated with current efforts to refine  $R_s$  in flume studies using precision flow control, and plans to field validate the approach at a U.S. Navy Munitions Response site in Fall 2015, specifically the former Live Impact Area at Vieques, Puerto Rico.

614

#### **SIMULTANEOUS DETERMINATION OF PER- AND POLYFLUOROALKYL SUBSTANCES IN LIVER AND MUSSEL SAMPLES**

I. Zabaleta, E. Bizkarguena, Analytical Chemistry; A. Vallejo, M. Ortiz, L. Fernández, University of the Basque country UPVEHU; A. Prieto, University of the Basque country UPVEHU / Analytical Chemistry; O. Zuloaga, University of the Basque country UPVEHU

An analytical method for the simultaneous determination of 14 perfluorinated compounds (PFCs), including 3 perfluoroalkylsulfonates (PFSA), 7 perfluorocarboxylic acids (PFCAs), 3 perfluorophosphonic acids (PFPA) and perfluorooctanesulfonamide (PFOSA), and 10 precursors, including 4 polyfluoroalkyl phosphates (PAPs), 4 fluorotelomer saturated acids (FTCAs) and 2 fluorotelomer unsaturated acids (FTUCAs) was developed in fish liver and mussel samples. After setting different variables affecting the chromatographic separation (column type and mobile phase), the electrospray ionization (capillary voltage, nebulizer pressure, drying gas temperature and drying gas flow) and mass spectrometric detection (fragmentor voltage and collision energy) of the target analytes, different clean-up strategies by means of solid phase extraction (SPE) using WAX, Envi-Carb or a combination of them were optimized and evaluated for the clean-up of focused ultrasonic solid-liquid (FUSLE) extracts. In all the cases the analysis was performed by liquid-chromatography-triple quadrupole mass spectrometry (LC-MS/MS). WAX coupled in-line to Envi-Carb was selected and validated in terms of recovery (external calibration using isotopically labeled analogues as surrogates and matrix-matched calibration approaches were tested) and method detection limits (MDLs). Recovery values in the 65-116 % and 59-119 % range and MDLs in the 0.1-2.7 ng/g and 0.1-3.8 ng/g range were obtained for liver and mussel samples, respectively. The developed method was applied to the analysis of grey mullet liver (*Chelon labrosus*) and mussel (*Mytilus galloprovincialis*) samples from the Basque Coast (North of Spain). In the case of liver samples perfluorooctane sulfonate (PFOS), PFOSA and perfluorodecanoic acid (PFDA) were detected. The highest average PFOS concentrations were observed in Gernika (988 ng/g) followed by Deba-Mutrikui (54 ng/g), Pasaia (35 ng/g), and Plentzia (26 ng/g). PFOSA and PFDA concentration were in the 4-15 ng/g and 1-2 ng/g range, respectively. In the case of mussels, although low concentration of PFOS (1.4-2.0 ng/g) and PFOSA (3-8 ng/g) were detected, 8:2 mono-substituted polyfluorodecyl phosphate (8:2 monoPAP) in the range of 21-86 ng/g was detected in Vigo, Pasaia, Santurtzi, Getxo and Muskiz. To our knowledge this is the first work where 24 per- and polyfluorinated compounds are determined in fish liver and mussel and the first time that the 8:2 monoPAP has been detected in mussels.

615

#### **Chemical Adsorption of Hydrophobic Persistent Organic Pollutants in the Marine Environment onto Microplastic Polymers and Subsequent Trophic Transfer**

C. Crawford, C. Ewins, University of the West of Scotland / Institute of Biomedical and Environmental Health Research; B. Quinn, Irish Centre for Environmental Toxicology (ICET) / Institute of Biomedical and Environmental Health Research; M. Russell, Marine Scotland Science / Marine Environmental Assessment

With an approximate degradation time of 450 years, plastic is one of the most durable and persistent environmental contaminants in the modern world. Production since the 1950s has increased prodigiously. In the marine environment, photo-oxidative degradation and the abrasive action of waves progressively degrade larger pieces of plastic into tiny polymer particles less than 5 millimetres in diameter, termed microplastics. Consequently, microplastics are inadvertently ingested by ocean dwelling biota, particularly susceptible filter feeders such as *Mytilus edulis*. Crucially, these organisms are located at the bottom of the food chain and recent research has demonstrated detrimental effects such as inhibition of gastrointestinal function and feeding impairment. However, it has newly emerged that microplastics are able to act as a transporter for the uptake of hydrophobic persistent organic pollutants (POPs) whereby hydrophobic organic chemicals (HOCs) become adsorbed onto the surface of the microplastic particles. Compounds such as polychlorinated biphenyls, which exhibit a broad spectrum of hydrophobicities, are particularly ubiquitous. Furthermore, increased chlorine substitution results in a decrease in susceptibility to photodecomposition by ultraviolet light and thus, resistance to degradation in the marine environment. Ingestion by biota, combined with the typical pH changes associated with digestion results in POPs leaching off the surface of the microplastics with the consequence of bioaccumulation within the organism. Since susceptible organisms are located at the bottom of the food chain, chemical adsorption provides a mechanism for trophic transfer up the food web to larger organisms, including humans. Consequently, chemical adsorption of a specifically nominated POP onto a polyethylene microplastic polymer organic phase was investigated to determine the sorption capacity of the microplastic in order to evaluate the level of contaminant capable of being transported. Furthermore, subsequent submersion of the microplastic in an

acidic pH environment at gut temperature enabled simulation of physiological conditions while facilitating investigation and quantification as to the level of POP leached into the surrounding medium. Consequently, this allowed determination as to the extent of leaching exhibited by POP coated polyethylene microplastics when exposed to a physiologically simulated chemical environment and the associated risk to marine biota.

#### **Challenges for environmental risk assessment of nanomaterials: addressing knowledge gaps, protection goals and regulatory perspectives**

616

#### **The Evolution of Risk Assessments of Manufactured Nanomaterials over the past 10 years - A regulatory perspective**

Y. Sultan, T. Francis, B. Fisher, Environment Canada

Regulatory bodies around the world continue to assess and manage potential risks associated with manufactured nanomaterials. Over the past decade we have seen a shift, from nanomaterials being considered completely novel and potentially requiring their own regulatory regime to the recent OECD Council Recommendation stating that nanomaterials can be safely regulated under existing regulatory frameworks, taking into account nano-specific considerations. To support existing regulatory programs, governments and jurisdictions are working together with their stakeholders, such as the scientific, industry, and NGO communities to ensure that decisions and approaches are scientifically robust. Examples of these activities will be highlighted in this presentation, which include: Canadian domestic activities such as the recent publication of the New Substances Program guidance on how new nanomaterials are considered under the New Substances Notifications Regulations (Chemicals and Polymers); The general agreement that categorization frameworks are appropriate for nanomaterials and the recent categorization work done under the Canada-US Regulatory Cooperation Council Nanotechnology Initiative and the OECD's Working Party on Manufactured Nanomaterials on how and when to use categorization schemes; The activities of the OECD WPMN Steering Group on Risk Assessment and Regulatory Program (SG-AP) which has a mandate to develop risk assessment and risk management approaches to support the OECD Council Recommendation. These include applying existing approaches used for conventional chemicals to nanomaterials, developing new approaches, and looking at cross-cutting issues such as categories of nanomaterials to address risk assessment *issues*; and Transition from focusing on physical-chemical properties as predictors for environmental or population level effects to looking at behavioural tests together with physical-chemical properties. In addition, this presentation will draw parallels between the regulatory approaches used for conventional chemicals and nanomaterials and provide future directions on regulatory needs to conduct both screening-level and data-rich risk assessments of manufactured nanomaterials.

617

#### **Adapting standard aquatic and sediment toxicity tests for use with manufactured nanomaterials: Key issues, expert consensus, and recommendations**

S.A. Diamond, NanoSafe Inc. / Midwest Division; G. Goss, University of Alberta; K.T. Ho, U.S. EPA / Atlantic Ecology Division; J. R. Lead, University of South Carolina / Center for Environmental NanoScience and Risk; S.K. Hanna, National Institute of Standards and Technology / Biosystems and Biomaterials Division; K. Hund-Rinke, Fraunhofer IME; A.J. Kennedy, CEERD-EPR; B.T. Mader, 3M / EHS Operations Environmental Laboratory; N. Manier, P. Pandar, INERIS; E. Petersen, National Institute of Standards & Technology; E. Salinas, BASF SE; P. Sayre, nanoRisk Analytics; K. Schwirn, German Federal Environment Agency; D. Völker, Federal Environment Agency, Germany

The unique properties of manufactured nanomaterials (MNs) suggest that their direct use or application in nano-enabled products will increase in the future. This will result in increased potential for human and environmental exposure to MNs during their manufacture, use, or disposal and suggests the need for MN-specific hazard and risk assessment approaches. Assessment of MN risk will require reliable, standardized hazard testing methods such as those provided by the Organization of Economic Cooperation and Development (OECD). However, guidance on how to design studies to address the many difficulties in testing MN, due to their particulate, fibrous, and colloidal properties, has yet to be developed. Here, we summarize findings from an expert workshop convened (as part of OECD's Working Party on Manufactured Nanomaterials ongoing activities) for the purpose of developing such a guidance document for aquatic and sediment testing. Workshop attendees (23 experts from 6 countries) identified critical components of test guidelines that will require additional or modified guidance. The discussion was based on attendees own research experience and on literature information elucidating the common issues related to material losses, dissolution, or modification in exposure systems and inconsistencies in testing practices. These include preparation of dispersions, exposure metrics, maintaining (and monitoring) consistent exposure levels, and reliable analytical and quantitative methods. In this presentation, we discuss these topics and identify where consensus was, and was not, achieved including the heavily-debated issues of use of dispersants,

manipulation of media properties (e.g. ionic strength or composition), testing unstable materials, using a water accommodated fraction approach, and adhering to the 20% exposure fluctuation thresholds (or applying other, MN-specific thresholds) common to many test guidelines. Workshop attendees also identified specific information gaps that might be addressed in future research to facilitate development of testing guidance. In addition to addressing standardized testing, the workshop findings will also facilitate more consistent testing and reporting of results in more exploratory research.

## 618

### **A transparent method to assess the regulatory adequacy of nanoecotoxicity studies**

N.B. Hartmann, Technical University of Denmark (DTU) / DTU Environment; H. Lützhøft, Technical University of Denmark / Department of Environmental Engineering; M. Agerstrand, Stockholm University / Environmental Science and Analytical Chemistry; A. Baun, DTU Environment / Department of Environmental Engineering

Environmental risk assessment of nanomaterials is required to ensure safety and protect the environment from unintentional adverse effects. In a regulatory context this requires reliable and relevant environmental hazard data upon which Predicted No-Effect Concentration (PNEC) values can be estimated. It is current practice that ecotoxicological studies are considered more valid for regulatory use if obtained according to accepted and validated test guidelines, preferably also following good laboratory practice (GLP). Evaluation of ecotoxicity studies is often done according to criteria specified by Klimisch et al. (1997), resulting in a so-called Klimisch score as a measure for study reliability. However, engineered nanomaterials (ENMs) are known to behave very differently in ecotoxicity test systems compared to soluble chemicals, for which most guidelines and the Klimisch method were intended. For this reason non-standard tests, or tests following modified test guidelines, may in some cases provide information of equal or higher reliability. Such data should therefore not *per se* be considered less reliable as basis for PNEC estimation. The aim of this paper was to develop a robust and transparent method to evaluate the reliability and relevance of ecotoxicity studies for nanomaterials. The development of this method draws on similar approaches developed for other groups of chemical and for evaluation of human toxicity data, as well as state-of-the-art knowledge on ecotoxicity test methods for nanomaterials. The result is a science based method that is practical and flexible enough to accommodate different types of nanomaterials and aquatic ecotoxicity studies. The method is directly applicable in regulatory frameworks such as in risk assessment under the European chemical legislation, REACH. Klimisch, H. J., Andreae, M., & Tillmann, U. (1997). A systematic approach for evaluating the quality of experimental toxicological and ecotoxicological data. *Regulatory Toxicology and Pharmacology* : RTP, 25(1), 1–5. doi:10.1006/rtp.1996.1076

## 619

### **Ecotoxicity testing strategy towards development for grouping of nanomaterials**

N.M. Deleebeeck, Arcadis Belgium / Environment; M. Messiaen, Arcadis Belgium nv; E.A. Bleeker, RIVM; D.T. Sijm, Head Bureau REACH; F. Van Broekhuizen, National Institute for Public Health and the Environment; K. Selles, Ecotox Services Australasia (ESA) laboratory

The use of nanomaterials in manufacturing operations and consumer products has increased as scientists and engineers have realized their benefits. The physicochemical characteristics of nanomaterials may differ from their non-nano counterparts, affecting such fundamental properties as solubility, reactivity, environmental transport, and toxicokinetics. This may introduce risks for humans or the environment. This study explores the physicochemical properties of nanomaterials and relevant ecotoxicological, kinetic, and exposure data in order to come to a strategy towards the development of concepts and criteria for grouping of nanomaterials for the purpose of testing for nanomaterial hazards and determination of potential risks. The proposed testing strategy involves four steps. In a first step, the known information is compiled, including information on potential read-across candidates. Next (step 2) a hypothesis is developed about how the nanomaterial might behave under relevant time scales and the effects following exposure. Specifically for the environmental compartment, solubility, substance identity (with coatings and composition as main characteristics), particle size and shape are mostly identified with hazard. For surface charge and reactivity, less information is available on the direct relationship with hazard and these are more used in a weight-of-evidence approach. To test the hypothesis (step 3) to what extent grouping can be used, in a first tier additional physico-chemical testing may be performed, in a next tier, ecotoxicity testing. In this first tier, water solubility/dispersibility and dissolution seem to be the main parameters affecting fate and behaviour in the environment, and are thus also of relevance for ecotoxicity testing. Comparison of nanomaterial behaviour under laboratory and environmental conditions indicates that agglomeration state, dissolution and dispersibility of nanomaterials are more variable under environmental conditions. Based on the solubility results of tier 1 testing, it can be decided if additional testing is needed. OECD Technical Guidelines relevant for ecotoxicity testing are applicable to nanomaterials, with some adjustments to the test protocols. From the data collected in the tiers, it can be assessed (step 4) if the nanomaterial has a unique behaviour or not. All the data can then be used in a weight-of-evidence approach to support the

grouping hypothesis.

## 620

### **Challenges in the environmental hazard assessment of nanomaterials under REACH: Information in REACH registration dossiers for aquatic toxicity**

L. Deydier Stephan, European Chemicals Agency / Evaluation Directorate; A. Kapanen, European Chemicals Agency - ECHA

Registration, Evaluation, Authorisation and Restriction of Chemicals (REACH), even if having no special provision that refers to nanomaterials, covers nanoforms of the substances. REACH Annexes from VII to X include standard information requirements for assessing environmental toxicity, fate and behaviour for all substances depending on the manufactured or imported quantities of the substance, including nanoforms. Dossiers registered under REACH regulation for substances known or detected as NMs were screened for acute and chronic aquatic toxicity results as part of the data available in the respective IUCLID dossiers. Around 20 dossiers and 15 different substances were analysed. Information in the aquatic toxicity studies including acute and long term toxicity testing on algae, aquatic invertebrates (mainly *Daphnia*) and Fish reported as key studies or supportive evidence were analysed. In addition, provided WoE (Weight of Evidence) to fulfil the information requirement or adaptations applied not to perform these tests were evaluated. The specific and general adaptations and information as key studies and test or preparations protocols have been analysed. Regardless of the data richness of the dossier, the reporting on the characteristics of the tested (nano)form, sample preparation, test performance and interpretation of the results was in many cases incomplete. In general, provided study summaries did not allow thorough evaluation of the appropriateness of the tested nanoform or the quality of the performed test. Short term testing was preferred in the dossiers for testing aquatic toxicity and requirement for long-term testing often adapted referring to: lack of exposure, natural abundance, insolubility, or technical difficulties in testing. Based on the observations in the screening of information on the aquatic toxicity in the NM related dossiers, a series of regulatory and scientific as reporting recommendations were made to improve the quality of the information for NMs. In conclusion majority of the challenges may be overcome with proper documentation of the sample characteristics, test protocols and interpretation of the obtained results with support of the foreseen adoption of new or updated test guidelines or guidance documents on protocols for dispersion and dissolution and ecotoxicity test protocols to be finalised within international organisation.

## 621

### **Output from a recent workshop on nanomaterial environmental risk assessment**

A. Palmqvist, Roskilde University / Department of Environmental Social and Spatial Change; L.F. Baker, Baylor University / Department of Environmental Sciences; V.E. Forbes, University of Nebraska Lincoln / School of Biological Sciences; A. Gergs, RWTH Aachen University / Department of Environmental Social and Spatial Change; F. Von der Kammer, Vienna University / Department of Environmental Geosciences; S.N. Luoma, University of California, Davis / John Muir Institute of the Environment; H. Lützhøft, Technical University of Denmark / Department of Environmental Engineering; E. Salinas, BASF SE; M.T. Sorensen, ENVIRON International Corporation / Senior Science Advisor; J. Steevens, US Army Engineer Research and Development Center

Although engineered nanomaterials (NMs) have been the focus of intense research during the last couple of decades, several issues related to developing a scientifically based environmental risk assessment (ERA) framework for such materials within existing legislation still remain unsolved. Research so far suggests that there may be particle specific complexities demanding a more NM-targeted approach to estimating environmental exposures and testing toxicological effects. In addition, studies on effects from chronic and environmentally realistic exposures are scarce in the published literature. To address these issues an international workshop was held on November 9, 2014 in Vancouver prior to the SETAC NA meeting. Through seven invited talks and a panel discussion, two overarching charge questions were addressed: 1) Is it prudent to assess environmental risk based on current knowledge and understanding of NM fate and effects?, and 2) How may we direct future research to address potential uncertainties and data-gaps? In addressing this, workshop participants acknowledged the pragmatic challenges in assessing NM risk based on existing methods and knowledge, and advocate that ERA is carried out with an understanding of identified uncertainties, challenges and limitations in NM effect- and exposure assessments. More specifically, since ERA should focus on what we are trying to protect, information may be needed beyond that found in published literature or produced by standard test guidelines, and therefore there is a need to allow inclusion of relevant nano-tailored studies in ERA. Efficient communication among researchers, regulators, and practitioners is essential to ensure effective assessments are conducted using appropriate endpoints and test conditions. This requires that the language and terminology used to describe fate, exposure, and biological effects of NMs, in addition to test procedures, mature to properly embrace specific particle complexities. In order to focus future NM research, it was generally agreed that one way forward could be to explore how models can be used to take a top down approach to identify: 1) what types of data and information are needed, 2) what parameters best predict nano-specific hazard and effects on protection goals, and 3) the information needed to make sense of the dynamic nature of different particle characteristics interacting

with environmental components. More detail on main workshop output will be provided.

## Assessing the exposome: Prioritization, biomonitoring, modeling and experimental assessment of exposure factors (I)

622

### Developmental neurotoxicity assessment of mixtures in children

P. Leonards, VU University, Institute for Environmental Studies / Institute for Environmental Studies IVM; M. Dingemans, IRAS

Worldwide, serious concern has arisen about the increased incidence of learning and developmental disorders in children. From a scientific point of view, there is no doubt that exposure to neurotoxic chemicals during early brain development can adversely affect learning and development. Various recent epidemiological studies have indicated that exposure to low doses of environmental biologically active contaminants (e.g. pesticides) during human development can have deleterious effects on cognitive development in childhood. The European commission-funded project DENAMIC "Developmental Neurotoxicity Assessment of Mixtures in Children" investigates neurotoxic effects (e.g. learning and developmental disorders) of low-concentration mixtures of pesticides and a number of common environmental pollutants in children. We focus on (subclinical) effects on learning (cognitive skills) and developmental disorders in children (e.g. ADHD, autism spectrum disorders and anxiety disorders). One of the aims is to develop better and sophisticated tools, procedures and testing methods to screen compounds for (developmental) neurotoxicity and to improve assessment of exposures and effects ([www.denamic-project.eu](http://www.denamic-project.eu)). As part of the project, a new alternative assessment strategy based on a combination of *in vitro*, *in vivo* assays and human exposure assessment is under development in order to prioritize compounds, and to further investigate the pathways and mechanism involved in disorders and diseases. The approach and results of DENAMIC will be presented.

623

### Multiscale connectivity - a high dimension biology approach to unravel the exposome

D.A. Sarigiannis, S. Karakitsios, Aristotle University of Thessaloniki / Chemical Engineering

The exposome represents the totality of exposures from conception onwards, simultaneously identifying, characterizing and quantifying the exogenous and endogenous exposures and modifiable risk factors that predispose to and predict diseases throughout a person's life span. Unravelling the exposome implies that both environmental exposures and genetic variation are reliably measured in tandem and linked through mechanistic analysis of toxicity pathways rather than only phenotypically associated. To better understand the interaction between environmental exposure and disease, we need to: (a) capture the biological perturbations initiated by exposure to environmental stressors; and (b) identify which of these perturbations overcome the homeostasis barrier, resulting in observed alterations of the cell/tissue environment and eventually to pathologic phenotypes. Towards this aim, integrated exposure biology provides the methodological elements for the surveillance of changes at different levels of biological organization through the use of the full array of -omics and post-omics technologies including epigenomics. Starting from untargeted transcriptomics and metabolomics we proceed with joint analysis of biological processes induced by exposure to xenobiotics at the molecular level and of metabolic processes induced in parallel. Dynamic flux balance analysis is a key element in the joint interpretation of gene expression data and metabolite profiles. This allows us to identify putative pathways of toxicity, which need to be verified by targeted multi-omics and functional assays. Identification of the functional links among the data derived from different high throughput testing platforms and their proper interpretation are supported by advanced bioinformatics such as support vector machines and clustering algorithms and systems biology models. Examples of the dawn of the exposure biology era are given and the future perspectives discussed in the context of supporting efficiently exposome studies.

624

### Toxicogenomic analysis of ambient Particle Matter (PM) from rural and urban environments

S.R. Mesquita, Center of Marine and Environmental Research CIIMAR / METOX Coastal and Marine Environmental Toxicology; B.L. van Drooge; E. Oliveira, IDAEA-CSIC / Environmental Chemistry; J.O. Grimalt, Environmental Chemistry; C. Barata, CSIC / Environmental Chemistry; N. Vieira, CIIMAR and Faculdade de Ciências da Universidade do Porto; L. Guimaraes, CIIMAR University of Porto / METOX Coastal and Marine Environmental Toxicology; B. Pina, IDAEA-CSIC / Environmental Chemistry

The toxic potential of the organic fraction of atmospheric particle matter (PM) of six sizes (>7.2; 7.2-3; 3-1.5; 1.5-1; 1-0.5; <0.5  $\mu\text{m}$ ) was studied for an urban site in Barcelona and a rural site in the Pyrenees (NE Spain), in warm and cold periods between 2012 and 2013. A yeast-based assay for dioxin-like activity (AhR-RYA) was used to first screen the samples, and the zebrafish embryotoxicity (ZET) assay

was used to analyze their *in vivo* toxicity. Dioxin-like activity was observed in both urban and rural samples, whereas only rural winter PM<0.5 $\mu\text{m}$  samples induced severe deformations and mortality on zebrafish embryos, related to their very high content on organic compounds. Selected samples of urban and rural PM were used for the transcriptome analysis of exposed embryos, along with a positive control performed with the classic dioxin-like compound Benzo[a]Pyrene (BaP, 0.1mg/l). Transcriptomic analyses of zebrafish embryos exposed to BaP, urban and rural PM extracts showed a strong (and similar) induction of the aryl hydrocarbon receptor signalling pathway (i.e. dioxin-like activity). Additional source-specific transcriptomic alterations were also observed. Rural samples (dominated by biomass burning emissions), activated genes related with neuronal function and inflammation, while urban samples (dominated by urban primary emissions, such as traffic) up-regulated biotransformation and oxidative stress gene cascades. This work emphasizes the need of a tighter surveillance on rural PM emissions from biomass combustion, particularly for PM<0.5  $\mu\text{m}$  and gives insights on which biological pathways are affected upon exposure to organic PM from urban and rural primary sources. *Acknowledgements - This study was supported by the Spanish Ministry through the project TEA-PARTICLE (CGL2011-29621; 2011-2013), and the Portuguese Foundation for Science and Technology for the doctoral grant of Sofia R. Mesquita (SFRH/BD/80710/2011) funded by the Program POPH - QREN through the Portuguese Ministry of Education and Science and the European Social Fund, and support through project PEst-C/MAR/LA0015/2013.*

625

### Recommendations for selecting biomarkers of exposure to organophosphate flame retardants in human biomonitoring

N. Van den Eede, Pharmaceutical Sciences; A. Covaci, University of Antwerp, Toxicological Center / Toxicological Centre

While the demand for flame retardants, such as organophosphate esters (PFRs), has increased, there are still major uncertainties regarding the human exposure to these compounds. Biomonitoring is considered the best approach to monitor internal exposure, yet little is known regarding the metabolic processes PFRs undergo in the human body and the identity of biomarkers of exposure. In the present study, we aim at presenting recommendations on the selection of the target biomarkers to be used when assessing the human exposure to PFRs through biomonitoring. These recommendations are largely based on our recently published *in vivo* and *in vitro* data completed with *in vivo* literature data. More precisely, we evaluate the usefulness of oxidative metabolites specific for one parent PFR as compared to non-specific or infrequently detected diesters formed by hydrolytic processes. Exposure biomonitoring studies for rapidly cleared chemicals require identification of stable (and specific) major metabolites for parent chemicals of interest. We have reported the *in vitro* metabolism of several PFRs, including tris(1-chloro-2-propyl) phosphate (TCIPP), tris(1,3-dichloro-2-propyl) phosphate (TDCIPP), tris(2-butoxyethyl) phosphate (TBOEP), ethylhexyl diphenyl phosphate (EHDPHP) and triphenyl phosphate (TPHP), by human liver enzymes. Several metabolites, such as diesters and oxidative metabolites, have been suggested as potential useful for biomonitoring in urine. For the selection of biomarkers for PFR exposure, we have based our conclusions on findings from biomonitoring (*in vivo*) studies in urine and on the identification of PFR metabolites in *in vitro* liver preparations. Together with the corresponding diesters (BDCIPP, BDCIPP, BBOEP, and DPHP), specific metabolites formed by oxidative metabolism, such as bis(1-chloro-2-propyl) 1-hydroxy-2-propyl phosphate (BCIPHP), (bis(2-butoxyethyl) 3'-hydroxy-2-butoxyethyl phosphate (HO-TBOEP), bis(2-butoxyethyl) 2-hydroxyethyl phosphate, and (hydroxyphenyl diphenyl phosphate (HO-TPHP), are suggested to be used in biomonitoring studies. The *in vivo* formation of some PFR metabolites has not been confirmed, and as a result, their suitability for human biomonitoring is still unknown.

626

### Patterns of accumulation of persistent organic pollutants in a representative sample of the population of Catalonia.

M. Garí, IDAEA-CSIC / Environmental Chemistry; J.O. Grimalt, Environmental Chemistry

Persistent organic pollutants (POPs) are man-made chemical compounds with notable toxicity potential and persistence, hence posing a threat to humans and the environment. This study focuses on the presence of POPs in a representative sample of the adult population of Catalonia, in the Western Mediterranean area. It is based on a public health survey conducted by the Government of Catalonia in 2002, including a health exam and a blood testing (human serum) for 919 people. Blood serum analysis was performed to measure the concentrations of a wide array of POPs, including organochlorine (OC) and organobromine (OB) compounds. Concerning OCs, hexachlorobenzene (HCB),  $\beta$ -hexachlorocyclohexane ( $\beta$ -HCH), 4,4'-dichlorodiphenyltrichloroethane (4,4'-DDT) and its major metabolite 4,4'-dichlorodiphenyldichloroethylene (4,4'-DDE), and polychlorobiphenyls (PCBs) were determined by gas chromatography with electron capture detection (GC-ECD). Concerning OBs, different congeners of polibromodiphenyl ethers (PBDEs), including BDE-209, were determined by gas chromatography coupled to mass spectrometry operating in negative chemical ionization mode (GC-MS-NICI). All the studied individuals from the population of Catalonia show detectable levels of POPs, for at least one compound. In general terms, the OC concentrations in the population of Catalonia are equivalent to those described for other populations

worldwide. Concerning PBDEs, their concentrations rank amongst the highest in the world, with the exception of North America and highly-polluted sites. Age, sex and the body mass index are strong determinants in the patterns of accumulation of OCs and PBDEs. The concentrations of OCs increase with age while the concentrations of PBDEs are higher in young individuals (Sexual differences are also observed: with increasing age, women have higher concentrations of several OCs, particularly HCB and  $\beta$ -HCH. Furthermore, the influence of the body mass index in the accumulation of these compounds is proportionately higher among men than in women. These differential trends may probably lie in the conjunction of both the physical-chemical properties of these compounds and the dynamics of human metabolism. Other socio-demographic determinants such as educational level, social class and place of birth contribute less to explain the accumulation of POPs in the studied population.

## Effect Modelling of environmental systems - extrapolation and prediction of species response (I)

627

### Assessing data needs, precision of parameter estimates and goodness-of-fit of model predictions for TK/TD models: chlorpyrifos as a test case

A. Focks, Alterra Wageningen University and Research Centre / Ecotoxicology Environmental Risk Assessment Team; M.N. Rubach, Syngenta Crop Protection AG / Global Regulatory; M. Zafar, Quaid-i-Azam University; R. Ashauer, University of York / Environment; P.J. van den Brink, Alterra and Wageningen University

Toxicokinetic-toxicodynamic models provide exciting opportunities in linking exposure with effects. These opportunities are accessible, however, only when the models are properly parameterised, an exercise still necessary for each and every combination of species and chemical. The data needs and related effort for parameterising TK/TD models were considered to be quite high for long times. Recently, Nyman et al. investigated the influence of the availability of internal concentration data on the goodness of fits of survival probabilities for propiconazole in *Gammarus pulex* for different TK/TD model types. They found that the goodness-of-fit of model predictions did not improve significantly if data on internal concentrations were considered for the parameterisation. Based on a comprehensive dataset for the organophosphate insecticide Chlorpyrifos, we extended the questions of Nyman et al. by additionally considering whether absolute values and confidence intervals of estimated model parameter are dependent on knowledge about toxicokinetics. The dataset offered the unique opportunity to analyse related questions for a set of 14 macroinvertebrate species and to test the goodness of fit of different model parameterisations by using survival data for 6 of those 14 species under pulsed exposures. More information is given in the extended abstract.

### Can toxicokinetic and dynamic modelling be used to understand, quantify and predict synergistic interactions between chemicals?

N. Cedergreen, K. Dalhoff, M. Gottardi, University of Copenhagen / Department of Plant and Environmental Sciences; A.C. Kretschmann, University of Copenhagen Mixture toxicity models such as Concentration Addition and Independent Action have shown to predict non-interactive mixtures well. Some chemicals do, however, interact by either enhancing or decreasing the effect of each other. The question is to what degree toxicokinetic (TK) and toxicodynamic (TD) models can be used to understand, quantify and predict the joint effect of interacting mixtures? To investigate this we have developed a TKTD model for the synergistic azole/pyrethroid mixture. We have parameterised it using the azole propiconazole together with the pyrethroid  $\alpha$ -cypermethrin in the aquatic crustacean *Daphnia magna*. Uptake and elimination kinetics of  $\alpha$ -cypermethrin in the absence and presence of propiconazole was measured to parameterise the TK part of the model, testing the hypothesis that propiconazole affects the elimination rate constant of  $\alpha$ -cypermethrin only. The immobility of daphnids monitored during four days after an  $\alpha$ -cypermethrin pulses of varying concentrations was used to parameterise the TD part of the model. The hypothesis that the synergistic enhancement of  $\alpha$ -cypermethrin toxicity in the presence of propiconazole can be explained by a prolonged internal  $\alpha$ -cypermethrin concentration in the propiconazole treated daphnids, was tested on a dataset of daphnids conducted as described above, but in the presence of 500  $\mu\text{g/L}$  propiconazole. Predicting immobility with the TKTD model with the  $\alpha$ -cypermethrin elimination rate constant being the only parameter affected in the presence of propiconazole explained 60% of the variance in the data. Increasing the killing rate approximately four-fold improved the fit to explain 80% of the variance in the data. We conclude that the TK data could be well described by assuming propiconazole decreasing  $\alpha$ -cypermethrin elimination rates, probably by inhibition of P450 monooxygenases. The increase in toxicity of the mixture, however, could not solely be explained by prolonged  $\alpha$ -cypermethrin presence inside the organism, but also the killing rate seemed to be affected by the presence of propiconazole.

### How toxicokinetic and toxicodynamic processes contribute to the time dependency of toxicity? - A modeling case study for different adverse outcome

#### pathways

C. Vogs, Department Bioanalytical Ecotoxicology; R. Altenburger, UFC Centre for Environmental Research / Department of Bioanalytical Ecotoxicology  
Abstract The time course of toxicological effects of chemicals may result from toxicokinetic and toxicodynamic processes. This study seeks to characterize whether toxicokinetics or toxicodynamics dominates the perturbed growth of the green algae *Scenedesmus vacuolatus* for different kinetics of bioconcentration and adverse outcome pathways. To this end, comprehensive data of internal effect concentrations and the related affected growth profiles were used for effect modeling of concentration-time-response relationships. The choice of six model chemicals was based on the expected time to reach equilibrium concentrations in the algae cells according to a hydrophobicity-driven partition process combined with the suspected time to progress the effect from the initiating event to the adverse outcome through key toxicity pathways. As a result, delayed toxicity occurred to be mainly dominated by the toxicodynamic processes. The predicted kinetic rates characterizing the effect progression ranged over six orders of magnitude in the following order: inhibitor of the photosystem II > reactive chemicals > inhibitor of lipid synthesis. Kinetics of effect progression were quantified to be specific for different adverse outcome pathways and seemed to be independent of whether equilibrium concentrations in the algae were reached over minutes or hours. The determination of effect progression rates might help to characterize and distinguish different adverse outcome pathways. **Keywords:** phytotoxicity, modes of toxic action, toxicokinetic-toxicodynamic modeling, hypothesis-based experimental set up

### Death dilemma and organism recovery: toxicodynamic patterns in chemical space

R. Ashauer, University of York / Environment; I.A. O'Connor, Pflanzenschutzchemie; A. Hintermeister, TESTEX AG / Analytics Department; B.I. Escher, Helmholtz Centre for Environmental Research GmbH - UFZ / Cell Toxicology

Why do some individuals survive after exposure to chemicals while others die? Either the tolerance threshold is distributed amongst the individuals in a population, and its exceedance leads to certain death, or all individuals share the same threshold above which death occurs stochastically. Both assumptions lead to the typically observed sigmoidal dose-response curves, but the time course of mortality differs markedly. More importantly, if one were to assume stochastic death one would conclude systematically stronger compensation and damage repair mechanisms than with the assumption of individual tolerance. Thus we face a circular conclusion dilemma because inference about the death mechanism is inherently linked to the speed of damage recovery. Recent theoretical advances have established a mathematical relationship between the two assumptions and resulted in the General Unified Threshold model of Survival (GUTS). In previous work we experimentally quantified the uptake, biotransformation and elimination rates of 14 synthetic organic chemicals in the aquatic invertebrate *Gammarus pulex* and built a toxicokinetic model. But now we were able to construct a toxicokinetic-toxicodynamic model for each compound where the toxicokinetic part simulates the time course of the internal concentrations. The sums of internal concentrations of the toxicologically active chemicals were the inputs for the toxicodynamic model part. We include mixture effects by explicitly modelling the biotransformation products and their contribution to toxicity. Stochastic death (SD) and individual tolerance (IT) were about equally likely. By separating toxicokinetics from toxicodynamics, we studied the position of chemicals in the toxicodynamic parameter space and found patterns and clusters amongst chemicals related to modes of toxic action. Thus we suggest toxicodynamic parameters as novel phenotypic anchors for *in vitro* to *in vivo* toxicity extrapolation. For all chemicals IT was associated with smaller recovery rates than SD, which confirms the expectation that organism recovery is slower in case of IT as compared to SD. This means that any given survival data can be explained by either slower organism recovery and a wider individual tolerance distribution, or faster organism recovery paired with a narrow tolerance distribution in the test population. What's more: GUTS debunks the myth of asymptotic LC50s.

631

### Species sensitivity and metabolic rate

J. Baas, Centre for Ecology & Hydrology; S.A. Kooijman, Vrije Universiteit Ecotoxicological studies have shown considerable variation in species sensitivity for chemical compounds, but general patterns in sensitivity are still not known. A better understanding of this sensitivity is important in the context of environmental risk assessment but also in a more general ecological and evolutionary one. We investigated the metabolic rate or more precise the specific somatic maintenance (expressed in  $\text{J}\cdot\text{cm}^{-3}\cdot\text{d}^{-1}$ , at a standardised body temperature of 20 °C) on the sensitivity of a species to chemical poisoning. The sensitivity of a species was expressed in terms of its threshold concentration for survival in the simplest toxicokinetic toxicodynamic model available, the No Effect Concentration (NEC, expressed in  $\mu\text{mol/L}$ ). Somatic maintenance data were based on the 'add-my-pet' database hosted by the VU University of Amsterdam. NECs were derived from the US-EPA ECOTOX database. We focussed on 4 pesticides; 2 that need a metabolic activation, Chlorpyrifos and Malathion, and two without metabolic activation, Carbofuran and Carbaryl. All 4 pesticides showed a similar response in over 50

different species in total: a strong negative correlation between the specific somatic maintenance and the *NEC*. This intuitively makes sense, species with a higher metabolic rate are more susceptible for interference with toxicants. The metabolic rate is not the only trait that makes species more or less sensitive to toxicants, however using species traits to get a first appraisal on their sensitivity to chemical stress is a promising line of research

632

#### **Inter-species and inter-level transferability of ecotoxicological test results**

A. Gergs, RWTH Aachen University / Department of Environmental Social and Spatial Change; T.G. Preuss, Bayer CropScience / Environmental Modelling  
Environmental risk assessment of chemicals is largely based on adverse effects measured for individuals belonging to standard species under laboratory conditions. Protection goals for environmental risk assessment usually include non-target species as well as the populations and communities they constitute. Interspecies differences and interactions between chemical, physical and biological factors are thereby generally unaccounted for. Uncertainties in the risk assessment procedure are thus related to the extrapolation of ecotoxicological test results to non-standard species and higher level protection goal such as populations. To bridge this gap between effect measures and protection goals and to account for various species in variable environments, we need predictive modeling approaches. Therefore, process-based mechanistic effect models, that take underlying physiological and ecological mechanisms into account, are gaining resonance in scientific and regulatory communities as a means to bring more ecological realism and more informed predictions into ecological risk assessment of chemicals. In this regard, we raise the question if effects on populations that belong to a certain species are predictable from effect measures derived from ecotoxicological tests using a different species. In a toxicokinetic-toxicodynamic modelling approach we assume that differences in effects among species and among different life stages within a species are the result of differential toxicokinetics, i.e. the process translating exposure to body residues. We test this assumption based on acute toxicity tests employing three aquatic species, the water flea *Daphnia magna*, the copepod *Mesocyclops leuckarti* and the larval phantom midge *Chaoborus crystallinus*, exposed to triphenyltin. In a second step we extrapolate acute effects observed for *M. leuckarti* and *C. crystallinus* to populations of *D. magna* by integrating the toxicokinetic-toxicodynamic model in an individual-based population model framework. The approach is evaluated by confronting model predictions with independent population data. While we conclude that the inter-species and inter-level extrapolation of ecotoxicological test results is feasible to some extent, we also discuss limitations for the presented model.

### **Addressing data collection and computational challenges in LCI (I)**

633

#### **TOWARDS A GLOBAL NETWORK OF INTEROPERABLE LCA DATABASES**

L. Mila i Canals, UNEP; A. Asselin, UNEP DTIE Paris / SCP; H. Cruyppenninck, UNEP-DTIE; S. Liu, USDA; W. Ingwersen, US EPA; T. MacDonald, U.S. Environmental Protection Agency / Office of International Affairs

**Introduction.** Meetings on international LCA cooperation have been held since 2012 among governmental and intergovernmental organizations towards advancing the development and application of life cycle assessment as a tool for sustainability in decision making and public policy. Within this framework, a meeting organized by UNEP, US EPA and USDA was held in April 2014 in Washington D.C., specifically focused on LCA data and databases with more than 60 participants (governments and LCA database experts) from 17 countries. **Purpose.** The objective of the meeting was to develop a vision, guiding principles and an approach for implementing a voluntary international network to promote LCA data accessibility, interoperability and applications, and define a proposed work plan for moving such an initiative forward. **Results.** The two-day interactive workshop on LCA data and database interoperability, and follow-up governmental meeting to consider proposals from the workshop (as well as review experience of LCA applications in public policy, other data quality issues, and capacity building interests) resulted in an executive summary, including proposed “Next Steps on Building a Global Network of Interoperable LCA Databases.” Key elements included a proposed governance structure to help create a global LCA database network, as well as a proposed set of early deliverables. Results related to governance included: Forming an interim planning group (IPG) composed of governments and international organizations to better defining the initiative and propose a long term governance structure, including the establishment of a Steering Committee that would supersede the IPG. The IPG should also establish a Technical Advisory Group (TAG) to advise and support the IPG and subsequent Steering Committee, including in efforts constitute and to define terms of reference for various Working Groups. Working Groups would be the operational units of the initiative created for a limited durations and focused on particular tasks products, or other deliverables. Working groups were proposed to take on development of several “Early Deliverables” identified as key resources to help shape development of a Global Network of Interoperable LCA Databases, including: Identifying network options: exploring the technical and organizational options, the level of

data harmonization needed, the possibility of user access to the network, and related costs and timelines  
**Determining metadata descriptors:** describing the metadata to accompany datasets that would be available through a data network and providing examples of descriptors and explanations of how metadata might be used in the context of integrating various datasets  
**Narrowing nomenclature gaps:** investigating opportunities for consensus building on LCA flows nomenclature in order to help reduce current divergences that hamper interoperability  
The IPG has already begun consultations among identified representatives of this group, and further outreach is being done to enlist other country interests among these who also manage or support national or regional LCA databases or database network, or have a concrete plan to build one, and have an interest in participating in being part of the proposed global network. This presentation will also include additional information on this initiative expected to emerge from the fourth international meeting on governmental LCA cooperation planned for March 2015 in Malaysia.

634

#### **Steps toward a global open source LCI database**

M. DESAXCE, 2.-0 LCA consultants; B.P. Weidema, Aalborg University / Danish Centre for Environmental Assessment

This paper describes the BONSAI database initiative – a not-for-profit, open source community initiative, using semantic wiki technology and automatic data harvesting to increase the free access to structured LCI data. The initiative aims at ensuring completeness by embedding the LCI data in a global multi-regional input-output framework and a top-down approach to impact assessment to cover all known biophysical, economic and social impacts. The presentation shows how BONSAI integrates the experience from other LCI databases and open source initiatives, while adding innovative elements for raw data harvesting, data consolidation, validation, review, system modelling, uncertainty propagation, and user interfaces. The current challenges and status of the initiative and its 10 working groups are presented.

635

#### **Towards a global regionalised inventory of thermoelectric power plants and their emissions**

C.E. Raptis, Institute of Environmental Engineering; S. Pfister, ETH Zurich

The electricity industry has been the focus of many LCA studies, owing to the many different impacts associated with their operation. Nowadays it is difficult to imagine a product or process that does not involve electricity production, therefore, being able to access a global, regionalised inventory of emissions per unit of energy produced becomes all the more important. In this work we present the first steps and results of our holistic and systematic approach to creating a global, spatially explicit inventory for thermoelectric power plants, based on analysis of the data available in the Platts World Electric Power Plant (WEPP) database. Starting by systematically georeferencing the power plants we proceed to carry out a computationally intense data analysis, permitting the calculation of the thermal efficiency of each individual thermoelectric generating unit. These thermal efficiencies are improved compared to generic estimates based on the fuel used, often encountered for thermoelectric plants, and can be further employed in the calculation of emissions important to LCA, or ones never calculated so far, such as freshwater thermal emissions. We present the steps in the data analysis, followed by the results for both thermal efficiencies and freshwater thermal emissions per power plant technology, fuel type and MJ of electricity produced on a 0.5x0.5 degree grid scale with global coverage. Freshwater thermal impacts are expected to be highly regional, making an analysis on this level of geographical detail crucial. Preliminary results for a fraction of thermoelectric power plants using once-through cooling systems and subcritical steam conditions show that the highest absolute freshwater thermal emissions come from nuclear power plants, but that the fraction of heat rejected/electricity produced is similar between the power plants of this category. As an example for coal-fueled power plants on average 2.4 MW are emitted into freshwater for every MW of electricity produced, for gas-fueled power plants this value is 2.3 MW/MW and for nuclear power plants this value is equal to 2.9 MW/MW. We analyse the variability in all results in terms of fuel and technology type, and in terms of the location of the power plant. We discuss the advantages and limitations of our approach, with particular focus on the need to fill in patchy data, and we present our future steps in completing the global, regionalised set of emission data for thermoelectric power plants.

#### **Applying information retrieval to gross margin handbooks: A method to create site-specific LCIs at national scale and farm level**

J. Navarro, CSIRO Land and Water / Land and Water Flagship; B. Bryan, O. Marinoni, CSIRO / Land and Water Flagship; S. Eady, CSIRO / Agriculture Flagship; A.B. Halog, University of Maine / Geography, Planning and Environmental Management

Finding optimal solutions for sustainable intensification requires research that models agricultural production from a system's perspective at the local, landscape and national scales. This is so the relationship between on-farm activities, yields, and large-scale impacts can be better understood. In this paper we present a new method to produce spatially-explicit life cycle inventories based on the combination of data from gross margin handbooks with spatial datasets at farm level resolution (1km<sup>2</sup>). The method uses natural language processing techniques and an

implementation of an information retrieval method used in popular web search engines (query expansion with background knowledge). We applied our method to produce crop life cycle inventories for the whole of Australia at 1km<sup>2</sup> resolution, and validated modelled fertiliser, pesticide and fuel use against the best available datasets at the national and local scales. The model covers the 72 highest ranked broad-acre and horticultural crops in terms of area coverage and economic value in Australia. Its results can be scaled up to analyse the baseline environmental impacts at the landscape, regional or national level. Our method delivers valuable information for on-farm decision making and contributes to the design of more cost-effective policies around sustainable intensification or land sparing by providing policy-makers with a greater understanding of the relationship between small-scale actions and large-scale impacts

637

**A Novel Approach for Inclusion of LUC from Biofuels in Consequential LCA**  
Y. Cikovani, Technische Universität Darmstadt / Civil and Environmental Engineering; L. Schebek, Technische Universität Darmstadt / Material Flow Management and Resource Economy; R. Schaldach, F. Wimmer, University of Kassel CESR

Keywords: biofuels, spatially explicit land use modelling, computational methods  
Biofuels are considered a major option for the mitigation of climate change and have therefore been included in climate policies worldwide. However, several studies gave insight that the demand for agricultural biomass as feedstock for biofuels may induce land use change (LUC) and might even offset the savings of greenhouse gas (GHG) emissions by the replacement of fossil fuels. Studies based on these approaches give valuable insights, but generally on a spatial very aggregated level. To overcome these limitations and as to including sophisticated data in LCI within CLCA, we developed a novel approach of coupling LCA with the spatial explicit land use change simulation model LandSHIFT (Land Simulation to Harmonize and Integrate Freshwater Availability and the Terrestrial Environment) in an integrated and automatized IT-tool which comprises interfaces between all tasks of concern. The model input is a set of exogenous drivers such as population and production of agricultural commodities. The model output is a time series of high resolution raster maps of the changing land use pattern. The LandSHIFT output data, i.e. output raster maps, can be processed within LCA for a determined scenario. Benefit of this approach is that GHG emissions not only can be investigated as to different demand scenarios, but moreover within one and the same scenario, impacts and effects of relevant parameters - such as the influence of technology efficiencies, changes in land productivities, influence of feedstock and technology compositions etc. - can be evaluated in order to provide specific on-site recommendations for action. Summing up, this computational approach enables the fine-tuning of LCA data regarding land use change from biofuels within the framework of CLCA factoring in socioeconomic as well as biophysical aspects. The approach integrates a computational tool outside of the LCA sphere, yet is coupled to LCA and can improve sophistication of LCI data. Thus, the generated data is implemented as to a parameterization of conventional LCA-database. This approach therefore supports decision making on a regional level and facilitates governing the complexity of environmental aspects and management practices to regional stakeholders and brings forward the current insights regarding spatial, temporal and uncertainty issues in a holistic manner.

638

**Life Cycle inventory of chemical emissions during product use: A parsimonious emission model of chemicals encapsulated in products**

L. Huang, University of Michigan / Dept of Environmental Health Sciences School of Public Health; O. Jolliet, University of Michigan / Environmental Health Sciences School of Public Health

Current approaches for life cycle inventory calculations in life cycle assessment (LCA) have primarily focused on the impacts of outdoor emissions or the manufacturing stage without considering near-field releases and exposures during product use. However, studies have demonstrated that near-field chemical intakes may exceed environmentally mediated exposures and are therefore essential to be considered when assessing chemical emissions across a product's life cycle. Chemicals encapsulated in materials/products can be a major emission source in the use phase. This includes for example volatile organic compounds (VOCs) in building materials and flame retardants in furniture/consumer products. Previous models describing such emissions require complex analytical or numerical solutions, which poses a great computational burden and lack transparency. In the present study, we adapted a model which describes VOC emissions from building materials and subsequent loss by ventilation, and simplified the governing equations by assuming a pseudo-steady-state between emission and loss. The solution of the simplified governing equations for total mass emitted, which consist of a sum of infinite exponential terms (2000 – 5000 terms are needed to be accurate), was further reduced to a sum of only two exponentials. Results show that this simple two-exponential solution can approximate the real total mass emitted over 15 years with R-square greater than 0.99 for a wide range of compounds. This approach greatly reduces the computational burden, and can be easily implemented in Excel, which is suitable for high-throughput modeling. Based on this approach, the emissions of chemicals encapsulated in products can be reported in the inventory either as the quantity of chemical inside a product over a certain time, with subsequent determination of product intake fraction in LCIA, or as indoor

releases, followed by application of the USEtox indoor model.

## Endocrine Disruptors: Exposure, Hazard & Risk Assessment (I)

639

**Which Aquatic Invertebrate Tests should be in the OECD Conceptual Framework for Testing and Assessment of Endocrine Disruptors?**

R.S. Benstead, Food and Environment Research Agency / Centre for Chemical Safety and Stewardship

The OECD Conceptual Framework for Testing and Assessment of Endocrine Disruptors (2012) sets out a framework for assessing the risk of chemicals having activities able to interact with the Estrogenic, Androgenic, Thyroidal and Steroidogenic (EATS) pathways in vertebrates. It proposes that two aspects are determined before a chemical can be referred to as endocrine disruptive. Firstly, the mode of action must be demonstrated to interfere with these pathways (by *in vitro* testing, or *in vivo* using biomarkers etc.), and secondly such effects should have a measurably adverse outcome. Invertebrates are also included in the Framework, but as yet, no tests are available for assessing EATS modes of action in these groups. In the absence of this information, this project makes an assessment of the responses of species and clades of invertebrates to compounds known to control these pathways in vertebrates, in order to identify those species that are most suited to use in the Conceptual Framework for the protection of invertebrate populations from chemicals regarded as endocrine disruptive under this definition. Research into relevant modes of action in invertebrates is in its infancy, but this should not defer the assessment of such chemicals in these organisms, and where there is a clear need to include invertebrate tests in the Conceptual Framework, these should be developed and proposed for regulatory risk assessment. Conversely, where invertebrate tests are not relevant for the purposes of the Conceptual Framework, they should not be included. In conclusion, the Guidance Document that includes the Conceptual Framework (OECD Guidance Document 150) states that 'the interpretation of results from invertebrate test guidelines is not included due to the rather poor current understanding of endocrinology in most invertebrates, and the lack of diagnostic screening endpoints with these taxonomic groups.' If the recommendations from this project are adopted, then interpretation of the invertebrate tests will be easier, since responses will be aligned to demonstrated wide-scale responsiveness in the invertebrate group used in testing, and the apical end-points measured will be conceptually linked to those observed in vertebrates.

640

**Targeted analytical toxicology: Simultaneous determination of 17 $\alpha$ -ethynylestradiol and the estrogen-induced vitellogenin biomarker**

F. Yang; W. Huang, W. Xie, Zhejiang University; C. Lu, Harvard School of Public Health / Environmental Health; W. Liu, Zhejiang University / College of Environmental and Resource Sciences

In most toxicological studies, chemical concentrations and its biological/molecular response (biomarker) levels are often quantified separately. We report a method, named as Targeted Analytical Toxicology (TAT), for simultaneous determination of levels of chemicals and protein biomarkers in organisms by UPLC/ESI-MS/MS on the basis of targeted proteomics. The TAT method is successfully applied to detect the concentrations of 17 $\alpha$ -ethynylestradiol (EE<sub>2</sub>) and EE<sub>2</sub>-induced vitellogenin (a biomarker for estrogens) in male zebrafish exposed to EE<sub>2</sub>. It is expected for TAT to have broad application in toxicology, especially environmental toxicology, due to its high sensitivity, accuracy, reproducibility, high throughput, and the savings of time, cost and labor.

641

**A frog is a frog is a frog...or is it? Variation in response of *Xenopus laevis* to oestrogen**

T. Hayes, UC Berkeley / Integrative Biology

Despite the acceptance of the African clawed frog (*Xenopus laevis*) as a laboratory model to examine endocrine disruptors, little is known about intraspecific variation in the response to hormones and endocrine disruptors in this model. In the current study, we evaluated the response of *X. laevis* to estradiol 17 $\beta$  (E2) using multiple sources of *X. laevis*. We identified significant variation in the response to E2 between populations of *X. laevis*. Animals from a commercial source (Nasco) and from a feral population from San Diego were very sensitive to E2 and responded to E2 concentrations as low as 30 pg/ml with genetic males developing ovaries. Animals from other commercial sources (Xenopus Express and Xenopus One) were least sensitive to E2 and did not respond until a concentration 100 times higher (3 Ng/ml). At 3 Ng/ml differences in sensitivity were also observed. In animals from a feral population from San Diego, up to 90% of the exposed males developed ovaries, compared to less than 15% sex reversal in all other populations, except the San Francisco population where E2 exposure at this concentration resulted in 50% hermaphrodites. Examination of multiple clutches per pair demonstrated that results were repeatable across clutches. Repeating experiments at 17 and 27 °C showed that temperature did not impact the effect of E2 on sex differentiation. Examination of multiple pairs within each population showed that the differences in sensitivity were repeatable within a population, with the exception of the population from Potchefstroom, where larvae from different pairs showed a range of sensitivity

that overlapped with populations deemed sensitive and insensitive. These data demonstrate that there is significant variation in sensitivity to estrogen between sources of *X. laevis*. Given the popularity of *X. laevis* as a model for examining endocrine disruptors, these findings are significant.

642

#### Are all chemicals endocrine disruptors?

J.R. Wheeler, Dow Agrosciences; S. Marty, Dow Chemical Company; E.M. Mihaich, ER2; L.S. Ortego, Bayer CropScience / Environmental Toxicology and Risk Assessment; K.K. Coady, The Dow Chemical Company / Toxicology Environmental Research and Consulting; L. Zorrilla, Bayer CropScience LP

Endocrine disrupting (ED) properties require evaluation under the European REACH regulation, as well as for regulation of plant protection and biocidal products. Specific criteria is under development in the EU to identify ED properties to enable hazard-based regulation, while in the US and Japan, risk-based approaches are being developed. Irrespective of the regulatory process, most geographies use the WHO IPCS definition, or variants thereof, requiring that a substance is demonstrated to cause a change in endocrine function that consequently leads to an adverse effect in an intact organism to identify it as an endocrine disruptor. Such a definition is broad and at its most cautious might capture many mechanisms that in general would not specifically be considered ED. For instance, stress is a non-specific, neuro-endocrine response that can lead to adverse outcomes. In addition, other toxic mechanisms (e.g. liver toxicity) may also secondarily impact the endocrine system and tissues. Furthermore, endocrine responses may be adaptive in nature, designed to maintain homeostasis, rather than inducing an irreversible adverse effect. Such factors should be considered when screening and testing substances for potential endocrine activity or disruption. Following the large scale screening of pesticides and pesticide inert under the USEPA's Endocrine Disruptor Screening Program, practical experience with screening assays has highlighted some of these factors as important to data interpretation and study design. Clearly, the misidentification of indirect effects as truly ED has serious consequences in terms of triggering unnecessary higher testing (animal and resource intensive) and potentially severe regulatory consequences in the EU (removal from the market). A review of effects that could be misinterpreted as ED was undertaken using both practical experience with the assays and relevant, peer-reviewed, scientific literature. Focus was on the ecotoxicology screens (fish short term reproduction and amphibian metamorphosis) while drawing parallels to mammalian toxicology. This work demonstrates that without a suitable framework for interpreting study results, potentially all chemicals could be considered ED at some exposure level, if too broad a definition of endocrine disruption is used. This presentation highlights the problem of distinguishing non-endocrine from endocrine mechanisms of action when operating in a purely hazard-based regulatory environment.

643

#### Hazard versus Risk Assessment of Endocrine Disruptors: A Communications Challenge

T.A. Verslycke, K.R. Reynolds Reid, Gradient

While *hazard* and *risk* are terms commonly used in everyday life, they are often misunderstood by the general public and poorly communicated by academia, industry, government, non-profits, and the media. There is certainly no lack of examples where public perception and outrage over environmental health risks has been at odds with the scientific assessment of these same risks. Similarly, *chemical hazard* and *chemical risk* are two distinct terms that are generally well understood by environmental toxicologists and chemists (i.e., the "SETAC community"), but are difficult to communicate beyond (and sometimes even within) this community. In an age of growing consumer scrutiny and information overload, it has become increasingly challenging to effectively communicate hazards and risks, as well as the benefits of chemicals and products. Endocrine disruptors are perhaps the textbook example of the challenges associated with communicating chemical hazards and risks. As illustrated in this presentation, the issue of endocrine disruptors is not only impacting industry through existing and pending chemical regulations, it also poses significant challenges for the development of credible and effective industry product stewardship programs. We reviewed several ongoing and pending chemical legislation initiatives related to endocrine disruptors in the EU and US (e.g., EU Plant Protection Product Regulation, EU Biocides Product Regulation, REACH, Endocrine Disruptor Screening Program, CA Green Chemistry Initiative). Similarly, we reviewed several product stewardship and chemical/product labeling schemes that have incorporated assessment of endocrine disruptors (e.g., GreenScreen<sup>®</sup> for Safer Chemicals, Chemistry Scoring Index, the Cradle to Cradle<sup>™</sup> Certified Product Standard, US EPA's Design for the Environment Program). Our review focused on how these regulatory and product stewardship initiatives address the issue of hazard *versus* risk-based evaluation of endocrine disruptors.

644

#### Are non-monotonic dose-response curves relevant to regulatory decision-making?

J.P. Myers, Environmental Health Sciences; L. Vandenberg, Tufts University

Endocrinology has acknowledged the existence of non-monotonic dose response curves as a basic attribute of hormone signaling for decades. Many examples have

now been published in peer-reviewed studies of endocrine-disrupting compounds. This phenomena, however, has yet to be incorporated in regulatory toxicology in the determination of chemical safety standards. We conducted thought experiments on whether non-monotonicity could interfere with calculation of determination of safe levels of exposure using standard procedures of regulatory toxicology considering three cases: (1) non-monotonicity occurs at high levels of exposure; (2) non-monotonicity takes place around the level that has been determined as the no-observed adverse effect level (NOAEL); and (3) non-monotonicity occurs within the range of the reference dose established by high dose experiments. We also queried the peer-reviewed literature to determine whether these conditions of each case actually occur. We found multiple examples of each case. We conclude that non-monotonicity is problematic for calculating safe levels of exposure because it occurs regularly at concentrations that would prevent its detection by regulatory toxicology as it is commonly practiced today.

## Ecotoxicology in tropical and polar regions (II)

645

#### Biological indicators for the impact assessment of (new) human activities in the Arctic

A.S. Szczybelski Ciordia, T. Kampen, C. Wang, Wageningen University / Aquatic Ecology and Water Quality Management; M. Van den Heuvel-Greve, Wageningen IMARES / Marine Coastal Systems; N.W. van den Brink, Wageningen University / Dept of Toxicology; A.A. Koelmans, Wageningen University / Aquatic Ecology and Water Quality Management Group

Marine sediments often act as a sink for bioaccumulative persistent chemicals, including oil or petrogenic PAHs. Sediment PAH composition may be altered due to weathering resulting in a heavier PAH mixture. Similar reasoning applies to other relevant compounds, such as PCBs. The current project aims to develop specific and sensitive biological indicators that can be used for impact assessment of oil and gas activities (O&G) and harbour development in the Arctic. Sediment samples and benthic species were collected above 67 degrees north in Kongsfjorden Bay (Svalbard, Norway), east of Kong Karls Land, south-east of Edgeøya and Snøhvit (Barents Sea); and in Eastern Scheldt and at Rotterdam harbour (The Netherlands) in 2013-2014 in order to evaluate the total and bioavailable organic pollutant (OP) baseline level at each location. Long-term exposure experiments to an OP-clean sediment (Eastern Scheldt) and to a mixture of different OP-clean : OP-contaminated sediment ratios (5 and 10% of Rotterdam harbour sediment) were carried out under controlled experimental conditions at IMARES (Yerseke, The Netherlands) and Kings Bay AS (Ny-Ålesund, Svalbard) in order to: (a) identify pressures and impacts of petroleum and combustion PAH sources and O&G equipment PCB sources, (b) identify pathways of exposure, linking economic activities to potential impacts on benthic organisms, and (c) explore the potential for read-across between Arctic (*M. calcareea*, *N. ciliata*) and Atlantic (*M. balthica*, *N. virens*) species. PAH and PCB baseline concentrations in sediment samples were analysed, and biota-sediment accumulation factors (BSAFs) in field and lab were determined. The sediment concentration analyses revealed low PAH or PCB concentrations in all Barents Sea and Kongsfjorden stations. The ratios BaA/228 and IP/(IP + Bghi) were used to identify the PAH sources. According to these ratios, PAH composition in samples collected inside Kongsfjorden Bay OP-clean areas (Blomstrand island and Kapp Guissee stations) indicated a petrogenic origin; PAHs in samples collected in stations located on Barents Sea depressions (E. Kong Karls Land – SE. Edgeøya) and in Snøhvit station probably originated during coal combustion; and PAHs in samples collected at Ny-Ålesund harbour station (Kongsfjorden Bay) are presumed to originate from combustion processes, like vehicle emission. BSAF data were interpreted using a mechanistic model.

#### Emerging Flame Retardants in Air in the Canadian Arctic

H. Hung, Environment Canada / Air Quality Processes Research Section; L.M. Jantunen, E. Sverko, Y. Yu, Environment Canada; E. Barresi, Environment Canada / National Laboratory for Environmental Testing; N. Alexandrou, Environment Canada / Air Quality Research Processes Section; P. Roach, Indian and Northern Affairs Canada (INAC); P. Fellin, AirZone One Ltd.; K. Nordin, Laberge Environmental Services

The Canada-operated Northern Contaminants Program (NCP) conducts measurements of persistent organic pollutants (POPs) and other priority organic pollutants in Arctic air at land-based stations since 1992. In collaboration with the ArcticNet program, air measurements of priority organic pollutants were also collected aboard cruises since 2007. Air samples were screened for new POPs and emerging organic pollutants to assess the long-range transport potential (L RTP) of these emerging pollutants in support of national and international control initiatives. To better understand and evaluate the effectiveness of control measures, temporal trends of these compounds in the environment are assessed. In this study, results from atmospheric measurements of emerging flame retardants (FRs), including brominated (BFRs), chlorinated (CFRs) and organophosphate (OPFRs) flame retardants, are reported in comparison with measurements of polybrominated diphenyl ethers (PBDEs). Non-BDE FRs including dechlorane plus (DP), 1,2-bis(2,4,6-tribromophenoxy)ethane (BTBPE), ally-2,4,6-tribromophenyl ether (ATE), 2-ethyl-1-hexyl 2,3,4,5-tetrabromo-benzoate (EHTBB),

bis(2-ethyl-1-hexyl)tetrabromophthalate (BEHTBP) and bis(2-ethyl-1-hexyl)tetrabromophthalate (TBPH), were frequently detectable in air at the Canadian Arctic station of Alert (82°30'N, 62°20'W). At the Yukon station of Little Fox Lake (61°21' N, 135°38' W), DP, dechlorane 602, pentabromotoluene (PBT), 2,3-dibromopropyl-2,4,6-tribromophenyl ether (DPTE), and hexabromobenzene (HBB) were frequently detected. Occasional high concentrations observed may be related to atmospheric transport episodes. Levels of OPFRs, including tris-chloroethyl phosphate (TCEP), tris-chloropropyl phosphate (TCPP), triphenyl phosphate (TPHP), ethyl-hexyl diphenyl phosphate (EHDPP) and tris-dichloropropyl phosphate (TDCPP), measured on cruises were higher than all other FRs in the Arctic. OPFRs arrive in the arctic sorbed to small particles.

#### **Immunomodulatory effects of In vitro and In vivo exposure to PCBs and perfluorinated compounds in East Greenland ringed seals**

M.J. Levin, University of Connecticut; J.W. Desforjes, Aarhus University (AU) / bioscience; E. Gabhard, University of Connecticut; R. Dietz, C. Sonne, Aarhus University / Department of Arctic Environment; R. Bossi, Environmental Science; R.J. Letcher, Environment Canada / Ecotoxicology and Wildlife Health Division; k. Gabrielsen, Norwegian University of Science and Technology / Biology; B.M. Jenssen, Norwegian University of Science and Technology / Dept of Biology; S. De Guise, University of Connecticut / Department of Pathobiology and Veterinary Science

To better elucidate the potential immune-related health effects of contaminant exposure on the health of sentinel arctic species, we collected high-quality tissue samples from 14 ringed seals (*Pusa hispida*) during the 2012 aboriginal subsistence harvest in East Greenland. We measured the concentration-response effects of in vitro exposure to various PCB congeners and perfluoroalkylated substances on mitogen-induced lymphocyte proliferation. Neither perfluorooctanoic acid (PFOA) nor perfluorooctane sulfonic acid (PFOS) modulated lymphocyte proliferation in the exposure range of 0 to 300 ppb. The non-coplanar PCB congeners CB-138, -153, and -180, but not the coplanar CB-169, reduced ringed seal lymphocyte proliferation between 10 and 20 ppm upon *in vitro* exposure. Serum levels of PFOA correlated with the concentration of cytokines measured from the supernatant of cultured lymphocytes; IL-15 ( $r^2=0.63$ ,  $p<0.05$ ) and IL-18 ( $r^2=0.83$ ,  $p<0.05$ ). Serum levels of PFOS and PFOA in free-ranging seals did not correlate with the proliferative response of lymphocytes. Concentrations of PCBs found to modulate immune function in this study are above the range measured in free-ranging ringed seals but within the range of other arctic marine mammals such as polar bears (*Ursus maritimus*) and killer whales (*Orca orca*), suggesting top predators are at risk for immunotoxic effects from environmental exposure of contaminants if they are as sensitive as the studied ringed seals. These results add to our understanding of the impacts of global pollution on arctic top predators and highlight the risk of increased susceptibility to novel pathogens and reduced overall health due to immunosuppression.

648

#### **The role of bird species in biological focussing of Persistent Organic Pollutants and as vectors for the long-range environmental transport of pollutants to the Antarctic**

S.J. Wild, Griffith University; I. Eulaers, University of Antwerp / Biology; A. Covaci, University of Antwerp, Toxicological Center / Toxicological Centre; D. Hawker, Griffith University / School of Environment; R. Cropp, Griffith University; L. Emmerson, C. Southwell, Australian Antarctic Division; S.M. Bengtson Nash, Griffith University / Southern Ocean Persistent Organic Pollutants Program SOPOPP

Persistent organic pollutants (POPs) many of which have a propensity for long-range environmental transport (LRET). LRET is however not the only transport mechanism by which these contaminants may reach the Antarctic. It has been proposed that POPs may be introduced into Antarctica by migratory biota, i.e. via the guano of birds and the introduction of carcasses to the food chain. The profile and concentration of contaminants transported by this alternative LRET is also likely to reflect lower-latitude migratory destinations. Little is known of the importance of this LRET pathway, although it is suspected to introduce POPs into Antarctica that are not subject of abiotic LRET. Chest muscle and guano from non-migratory Adélie penguin (*Pygoscelis adeliae*) and migratory south polar skua (*Stercorarius maccormicki*), and guano from endemic snow petrel (*Pagodroma nivea*) were collected from Adélie colonies in Antarctica. Samples were analysed for a range of legacy and modern POPs, including polychlorinated biphenyls (PCBs), organochlorine pesticides (OCPs) and brominated flame retardants (BFRs). The majority of target PCBs and OCPs were detected in muscle and guano of each species, except for a number of lighter PCB congeners only found in the skua. All samples were dominated by *p,p'*-DDE, and HCB, the two major compounds found in the Antarctic environment, as well as the larger PCB congeners with greater bioaccumulation potential. Although at much lower concentrations than the OCPs, The BFRs  $\alpha$ -HBCD and BDE-47 were found at highest concentration in skua and Adélie.  $\alpha$ -  $\beta$ - and  $\gamma$ -HBCD were the only BFRs found in petrel guano. PCB and OCP levels in samples of the migratory skua were usually 1 to 2 orders of magnitudes higher than those in the other two species, which may be reflective of both foraging region as well as trophic level. BFR

burdens were similar in all species. The similar profiles of PCBs and OCPs in muscle and guano suggests a shared food web. The greatest accumulation difference was seen in BFRs, with each species having unique profiles. Muscle and guano profiles were dissimilar to typical background atmospheric pollution. These results indicate the potential role of colonies of migratory and non-migratory species in the biological focussing of contamination in Antarctica. Migratory species carry the added potential for the direct introduction of recently emitted contamination at levels more consistent with source regions.

649

#### **Organochlorine pesticides in the marine environment of the Southern Ocean (Indian/Pacific Ocean sector)**

M. Bigot, Griffith School of Environment; D.C. Muir, Environment Canada / Aquatic Contaminants Research Division; D. Hawker, Griffith University / School of Environment; R. Cropp, Griffith University; J. Dachs, IDAEA-CSIC / Environmental Chemistry; C. Teixeira, Environment Canada; S.M. Bengtson Nash, Griffith University / Southern Ocean Persistent Organic Pollutants Program SOPOPP

Persistent Organic Pollutants (POPs) are ubiquitous anthropogenic chemical substances that have been widely used in agricultural and manufacturing industries. These compounds, which include a variety of organochlorine pesticides (OCPs), are highly resistant to biodegradation, capable of long-range environmental transport, are toxic and bioaccumulate in living organisms. The Stockholm Convention is a legally binding international treaty that seeks to ban or severely restrict the use and release of POPs into the environment to minimise the hazard they pose. Not all nations manufacturing POPs, however, are signatories. Many POPs are semi-volatile in nature. This has led to primarily atmospheric transport of part of the global POP burden to remote Polar Regions. At these cold conditions at high latitudes, their diminished volatility serves to restrict further movement. Global warming, however, stands to significantly alter the Polar climate and concerns have been raised over the possible inversion of POP movement in regions where there is currently net air to water flux. So-called "polar sinks" may, under this scenario, become secondary sources of POPs to the atmosphere, thus impacting global efforts to moderate human and environmental exposure to these toxic compounds. POP research in the Southern Ocean context remains insufficient to gauge the current magnitude of the Southern Ocean POP reservoir and further, to estimate the current net directional movement of chemicals at the air / ocean interface. Whilst a number of recent studies have focused on the POP burden of the marine environment of the south Atlantic sector of the Southern Ocean, limited studies have been conducted in the south Pacific sector in the past two decades. Here we present new knowledge regarding current levels and profiles of OCPs in the marine environment of the Indian/Pacific Ocean sector of the Southern Ocean. The study facilitates an improved understanding of OCP distribution in this global region. Environmental samples were collected along a transect from Australia to Antarctica on board the RSV Aurora Australis in February 2014. They were analysed for a suite of 31 organochlorine pesticides. Results of this sampling campaign will be presented and discussed.

#### **Challenges and Opportunities in Protecting Human and Ecosystem Health: Understanding the Fate, Transport, and Toxicity of Wastewater-borne Contaminants (II)**

#### **Human health risk assessment of amine emissions from post combustion plant technology**

S. Manzoor, A. Korre, Imperial College London South Kensington Campus / Earth Science and Engineering; A. Simperler, Imperial College London South Kensington Campus / Department of Chemistry

Amine solvents used for post combustion CO<sub>2</sub> capture (PCCC) produce compounds in the atmosphere, such as nitrosamines (NS) and nitramines (NA) that are a deleterious to the human health and the environment. Detailed amine atmospheric chemistry with dispersion calculations to assist in performing human health risk assessments remains a key knowledge gap. In this study, rate coefficients established through quantum chemical theoretical methods and kinetic modelling describing complex atmospheric chemistry mechanisms of the most commonly used amine for CO<sub>2</sub> capture, Monoethanolamine (MEA) and the degradation products, namely methylamine (MA) and dimethylamine (DA), are considered with dispersion studies for the UK's largest pilot plant, CCPilot 100+ in Ferrybridge, in the atmosphere using an air-dispersion model, ADMS 5. The developed methodology enables in determining reliable concentration of the resulting NS and NA in the atmosphere and their transport, dispersion and deposition away from the plant in time and space. Applying it to a worst case scenario of reactive amine emissions from a PCCC plant assists in assessing the risk posed to the human health by comparing to the reported as well as calculated safety limits. It is therefore suggested that this approach is reliable in determining the risk these amine emissions from PCCC technology pose to the humans. This methodology is applicable to any size of a power plant and at any geographical location

## Ecological fate and assessment of home and personal care products in Asia: Ecohope

C. Wannaz, The University of Michigan, Ann Arbor / SPHEHS; A. Franco, Unilever / Safety and Environmental Assurance Centre; J.E. Hodges, Unilever / SEAC; O. Jolliet, University of Michigan / Environmental Health Sciences School of Public Health

Risk assessment of down-the-drain chemicals typically focus on wastewater discharge from centralized systems, either at a large scale in a generic way, or at greater resolution at a lower scale. Discharges into surface water in many developing countries are less controlled, and in many cases can be considered more diffuse. This coupled with the increasing use of household (e.g. HPC) products in these regions requires new tools to assess the potential ecological impacts of HPCs, accounting for local hydrological and use characteristics. The aim of this project is therefore the development a geographically refined modelling framework to improve the environmental risk assessment of down-the-drain chemicals. We aim to develop a model to describe the hydrological and multimedia fate of releases associated with the use of household chemicals in Asia and Oceania. We then aim to combine the fate model with geo-referenced emission scenarios to predict chemical concentrations in the environment as a basis for performing ecological risk assessment at different scales (hotspots, countries, market clusters, eco-regions, continent). Geo-referenced emissions scenarios for eight test substances are first determined for the entire Asia using the ScenAT model, differentiating between treated and untreated wastewater discharge. These emission scenarios are then used as input to the Pangea fate and exposure model that has the ability to create scenario-specific multi-scale grids. As output the model yields chemical exposure maps and ecosystem risk characterization in river catchments across Asia. These are then used to identify hotspots that will warrant future refinement and the definition of archetypes for advanced ecological modelling. The presentation will compare resulting concentrations of different types of chemicals with different usages: LAS and triethanol amine esterquat (TEAQ) as ionic surfactants, triclosan and methylisothiazolinone (MIT) as antimicrobial and preservative, D5 as a siloxane emollient, permethrin as an insecticide and ibuprofen as a pharmaceutical, accounting for the chemical properties of each of these substances. Of special interest is the identification of locations with high exposure concentrations, resulting from different combinations of controlling factors: e.g. high population and emissions versus areas of low advection flow, long travel times of water to the sea.

## 652

### Quantification of plasticizers by UPLC-MS/MS in Besòs River and Risk assessment

G. Bolívar-Subirats; M. Cortina-Puig, Escola Universitària Salesiana de Sarrià; S. Lacorte, IDAEA-CSIC / Environmental Chemistry

Plasticizers are a group of substances added to plastics to modify their physical properties as flexibility or durability. These compounds have been used for a long period of time in the industry. Plasticizers are considered as emerging pollutants as a result of their extensive use and these compounds have an important interest due to their endocrine disrupting properties. The objectives of this study were to evaluate the presence of plasticizers along Besòs river waters (Catalonia, Spain) from source to mouth (17 sampling points, as it can be seen at Figure 1), study their seasonal variability and determine their risk. Sampling points included pristine areas close to the source, with little anthropogenic impact, and very impacted areas with high urban density and industrial activity. The Besòs River basin (Catalonia, Spain) is bordering the city of Barcelona in its northern part and is highly affected by urban and industrial pressures. It has a length of 17.7 km and a medium flow of 4.33 m<sup>3</sup>/s. The complete Besòs River basin has an area of 1,039 km<sup>2</sup> and it receives effluent discharges of 21 WWTPs. It has an industrial volume of more than 10,000 potential contaminant focuses and a population density of 2,000,000 inhabitants. For the analysis, solid phase extraction and ultra-high performance liquid chromatography-tandem mass spectrometry (UHPLC-MS/MS) operating in multiple reaction monitoring mode was used providing good sensitivity. This study demonstrates that ng/L concentrations of plasticizers in an impacted river do not produce any significant toxicity risk. However, other risk can be associated due to continuous inputs.

## 653

### Identification of anthropic impact on the food web using carbon and nitrogen stable isotopes as chemical markers. Case study: Three reservoirs with different eutrophication in Córdoba (Argentina).

J. Griboff, CONICET-UNIVERSIDAD NACIONAL DE CÓRDOBA / ICYTAC; M. Horacek, BLT WIESELBURG Lehr- und Forschungszentrum Francisco Josephi / Research Institute of Wildlife Ecology; M. Monferran, Universidad Nacional de Córdoba; D.A. Wunderlin, Universidad Nacional de Córdoba / ICYTAC DPTO QUÍMICA ORGÁNICA FACULTAD DE CIENCIAS QUÍMICAS

Stable isotopes have been used to trace the impact of anthropic activities, mainly untreated sewage discharges, in three reservoirs presenting different degrees of eutrophication. The main goal of our research was finding chemical-isotopic markers that could be used to link anthropic pollution with changes in different compartments in reservoirs, namely water, sediment, and different levels of the food web (plankton, shrimps and fish). Thus, we measured  $\delta^{13}\text{C}$  and  $\delta^{15}\text{N}$  values in

various organisms (from primary producers to upper consumers) to understand the influence of the different anthropogenic activities on the environment and the possibility to distinguish regions with different types of contamination, as well as areas of greater or lesser risk for food production. Study site samplings were carried out during the wet season (April 2014), after a massive rain event in three lakes in Córdoba, Argentina: San Roque, Los Molinos and Río Tercero lakes. San Roque Lake supplies drinking water to Córdoba city, and is also intended for recreational use. It is surrounded by cities and settlements which are not fully connected to the public sewage system. Los Molinos Lake provides water to the Southeastern area of the city of Córdoba and is used for recreational activities and irrigation. In the surrounding agriculture, mainly corn and sorghum are produced. Río Tercero Lake is the largest artificial reservoir in the province of Córdoba, and it is used for water supply and industrial activities, as well as for providing cooling water for a nuclear power plant. We collected water, sediment, plankton, shrimp (*Palaemonetes argentinus*) and fish (*Odontesthes bonariensis*) from each lake. Stable isotope analyses were performed in an Isotope Ratio Mass Spectrometer (IRMS), connected with an elemental analyzer (both Thermo Fisher Scientific). Results showed distinctive patterns in  $\delta^{13}\text{C}$  and  $\delta^{15}\text{N}$  between the lakes under study, allowing the identification of lakes more exposed to anthropogenic sewage. San Roque Lake showed the highest  $\delta^{15}\text{N}$  values for all the samples, indicating the most prominent influence of sewage on the lake ecology. Further research studies are being conducted to confirm this preliminary result, providing an interesting alternative to link sewage discharges with levels of stable isotopes in biota, including edible fish; thus, pointing out risk for people drinking water or eating fish from such impacted lakes.

## 654

### Seasonal persistence of wastewater-related micropollutants during transport along an urban river segment

G. Guillet, Tübingen University / Applied Geoscience; M. Schwientek, Water and Earth System Science; H. Ruegner, University of Tübingen / Water Earth System Science; B. Kuch, Institute for Sanitary Engineering Water Quality and Solid Waste Management University of Stuttgart; C. Zwiener, Environmental Analytical Chemistry, Center for Applied Geoscience, University of Tübingen / Geosciences; A. Jakimska, Gdansk University of Technology / Department of Analytical Chemistry; S. Merel, French School of Public Health / LERES; P. Grathwohl, Uni Tübingen / Center of Applied Geosciences

Organic micropollutants enter surface waters mainly via waste water treatment plants (WWTPs) effluents, due to incomplete removal, or combined sewer overflows. Little is known about the persistence and transport behavior of the substances released into the aquatic environment. To better identify involved attenuation processes within a selected study river segment and quantify temporal variability of the compounds' reactivity, detailed mass balances were determined over complete 24h cycles in July 2013 and February 2014, representing contrasting summer and winter conditions. Winter results allowed deepening the knowledge on the compounds' behavior in a selected test river segment, highlighting the importance of temporal variability of the compounds' reactivity within the same river section. The Steinlach River in southwest Germany has a total catchment area of 140km<sup>2</sup> and receives treated wastewater from a WWTP four kilometers upstream of its confluence with the Neckar River. Electrical conductivity signals were used to estimate stream velocity in order to sample the same parcel of water along this segment, in a lagrangian-like sampling scheme. A set of twelve 2h composite samples (sampling interval: 15min) were taken using automated samplers at the upstream and downstream ends of the segment, respectively, and analyzed in the lab. A novel transport modelling approach has been tested on winter concentrations to better understand removal pattern over a whole day. Transport modelling and comparison of mass balances demonstrated how the behavior of selected compounds differs on a daily as well as a seasonal scale within the same river section. The winter campaign was performed in order to observe how reactive compounds, in particular the likely photosensitive ones, behaved with weaker wintery insolation. Contrasting results compared to the summer sampling indicated that some processes identified in summer play a minor role in winter. A striking example is the pharmaceutical oxcarbazepine, described as highly reactive in summer but which was conservative along the same river segment during winter time. The synthetic musk fragrances also draw particular attention when comparing daily patterns in winter and summer. A more pronounced reactivity during day time in summer indicated that photodependent processes could be partly responsible for their natural attenuation. This trend is not observed in winter although mean removal rates were comparable with summer data.

## 655

### Transport of Nitrogen and Phosphorus from Onsite Wastewater Treatment Systems to Shallow Groundwater

G.S. Toor, University of Florida / Soil Water Science Department

The knowledge about the nutrients transport from the vadose zone of onsite wastewater treatment systems (commonly called septic systems) is crucial to protect groundwater quality as a large population on both developed and developing countries use septic systems to discharge household wastewater. For example, our preliminary data showed that about 47% of applied water was recovered at 60-cm below drainfield of septic systems. This implies that contaminants present in wastewater, if not attenuated in the vadose zone, can be

transported to shallow groundwater. This presentation will focus on the biophysical and hydrologic controls on the transport of nitrogen (N) and phosphorus (P) from the vadose of two conventional (drip dispersal, gravel trench) and an advanced (with aerobic and anaerobic medias) system. These systems were constructed using two rows of drip pipe (37 emitters/mound) placed 0.3 m apart in the center of 6 m x 0.6 m drainfield. Each system received 120 L of wastewater. During 20-month period (May 2012 to December 2013), soil-water samples were collected from the vadose zone using suction cup lysimeters installed at 0.30, 0.60, and 1.05 m depth and groundwater samples were collected from piezometers installed at 3-3.30 m depth below the drainfield. A complimentary 1-year study using smaller drainfields (0.5 m long, 0.9 m wide, 0.9 m high) was conducted to obtain better insights in the vadose zone. A variety of instruments (multi-probe sensors, suction cup lysimeters, piezometers, tensiometers) were installed in the vadose zones. Results showed that nitrification controlled N evolution in drainfield and subsequent transport of N plumes (>10 mg/L) into groundwater. Most of the wastewater applied soluble inorganic P (>10 mg/L) was quickly attenuated in the drainfield due to fixation (sorption, precipitation) in the vadose zone (< 0.10 mg/L), which was further reduced to < 0.05 mg/L in groundwater. The hydrologic controls (primarily rainfall during wet season of June-September) facilitated transport of N, but not P, to shallow groundwater. The advanced system was extremely effective as it removed >95% N from wastewater, but was less effective at removing P. This presentation will conclude with importance of better septic system design and soil-based processes in reducing N and P transport to groundwater and protecting water quality in aquifers.

## Contaminants of Emerging Concern in Food Webs: Impacts on Non-Target Organisms

656

### Screening of pharmaceuticals and endocrine disrupting compounds in macroalgae, bivalve, and fish from coastal areas in Europe

D. Alvarez-Muñoz; S. Rodriguez-Mozaz, Institute for Water Research (ICRA) / Water Quality; A. Maulvault, IPMA, I.P. / Division of Aquaculture and Seafood Upgrading; G. Fait, Aeiforia Srl; M. Fernandez-Tejedor, Institute of Agriculture and Food Research and Technology; F. Van de Heuvel, Hortimare Projects & Consultancy; M. Kotterman, IMARES / Fish; A.M. Marques, Portuguese Institute for the Sea and Atmosphere / Division of Aquaculture and Upgrading; D. Barcelo, IIQAB-CSIC / Institute for Environmental Assessment and Water Research  
This study focused on the presence and distribution of pharmaceuticals and endocrine disrupting compounds in several species of macroalgae, bivalves and fish collected in 2013 in different locations around Europe. The pharmaceuticals analysed includes compounds belonging to different therapeutic groups like psychiatric drugs, antibiotics,  $\beta$ -blockers, analgesics/anti-inflammatories, tranquilizers, diuretics, etc., and the endocrine disrupting compounds (EDCs) cover different families such as triazoles, flame retardants, hormones, stimulants, plasticizers, etc. The analysis revealed the presence of 7 pharmaceuticals in bivalves, between them azythromycin and velanfaxine were the most ubiquitous ones. The highest concentrations were observed for citalopram and velanfaxine, both psychiatric drugs, reaching up to 20.6 and 36.1 ng/g dry weight respectively in mussels from the Po delta in Italy, one of the top European sites for shellfish farming. In macroalgae and fish all the pharmaceuticals compounds analysed were below the method quantification or detection limits. In the case of EDCs for macroalgae the studied compounds were below the method detection limit while for fish and bivalves 10 compounds were detected at concentrations above the quantification limit. The highest concentration measured corresponded to Tris(2-butoxyethyl) phosphate (TBEP), a flame retardant, reaching up to 98.4 ng/g dry weight in mullet fish collected from the Tagus estuary in Portugal. The frequency of detection of the different contaminants analysed revealed a total of 20 compounds for pharmaceuticals and 10 for EDCs that can be pointed out as the most occurring ones in seafood and can be proposed for further study and as candidates for future monitoring campaigns.

657

### Understanding the fate and bioaccumulation of cyclic volatile methyl siloxanes in an Arctic lake

I.S. Krogseth, Norwegian Institute for Air Research / Environmental Chemistry; N.A. Warner, NILU - Norwegian Institute for Air Research / Environmental Chemistry; G.N. Christensen, Akvaplanntiva; M. Whelan, University of Leicester / Geography; K. Breivik, Norwegian Inst. for Air Research; A. Evenset; I. Wasbotten, Unilab analyse AS

Cyclic volatile methyl siloxanes (cVMS) are used in personal care products and are emitted to aquatic environments through wastewater effluents. Once present in aquatic environments, they can undergo volatilization, hydrolysis or sedimentation. In ice-covered lakes, volatilization of cVMS may be limited and rates of hydrolysis may be slowed down due to low temperatures. This could potentially increase the persistence of cVMS in these systems and hence increase exposure to aquatic organisms. The main objective of this study was to develop a holistic and mechanistic understanding of cVMS behavior by combining multimedia modeling and monitoring for an Arctic lake receiving unintentional wastewater emissions. The dynamic QWASI model and the aquatic module of the ACC-HUMAN model

were used to predict the seasonality of cVMS concentrations in Lake Storvannet in Hammerfest, Norway (70 °N, 23 °E). This lake receives sewage emissions from both leaking pipes and sewer overflow events, and is ice covered for approximately 6 months of the year. Lake water, surface sediments, one sediment core, Arctic char (*Salvelinus alpinus*) and Brown trout (*Salmo trutta*) from the lake, as well as nearby river water and wastewater were sampled in March and June of 2014. In addition, marine water, surface sediments, and Atlantic cod (*Gadus morhua*) were sampled from the nearby marine harbor, where the main municipal sewage outlet is currently located. Samples were analyzed for cVMS using established analytical methods. cVMS were detected in sewage, but were below limits of quantification in lake, river, and marine water. However, cVMS were detected in lake and marine surface sediments, and in deeper sediments deposited up to 30 years ago illustrating the persistence of these compounds. cVMS were also measured in liver tissue from both Brown trout, Arctic Char and Atlantic Cod with large variations between individual fish. The cVMS concentrations in freshwater fish are likely to be enhanced through benthic exposure, stressing the importance of the sediment compartment not only for persistence but also for bioaccumulation of cVMS. Temporal variations of cVMS concentrations in Storvannet will be driven by a combination of variable emissions and seasonality in environmental conditions, which will be further investigated through model simulations.

658

### Comparative Hazard and Exposure Assessment of Perfluoroalkyl Phosphonic and Phosphinic Acids (PFPA and PFPIAs): Are They Overlooked Emerging Contaminants?

Z. Wang, Swiss Federal Institute of Technology / Institute for Chemical and Bioengineering; I.T. Cousins, Stockholm University / Department of Environmental Science and Analytical Chemistry ACES; K. Hungerbuehler, ETH Zurich / Institute for Chemical and Bioengineering; M. Scheringer, ETH Zuerich  
Per- and polyfluoroalkyl substances (PFASs) are a large family of anthropogenic chemicals that have been widely used in various industrial and commercial applications since the 1950s. Among PFASs, perfluoroalkyl carboxylic acids (PFCAs) and perfluoroalkane sulfonic acids (PFASAs) have attracted most attention as emerging contaminants in the past decade because [i] PFCAs and PFASAs are persistent (P) and distributed ubiquitously in the global environment, biota and humans, and [ii] long-chain PFCAs and PFASAs are bioaccumulative (B) and toxic (T). Consequently, numerous studies and control actions have been conducted to understand and reduce the environmental and human exposure to these substances. However, recent (bio)monitoring studies show that wildlife and humans are exposed to a wide range of unidentified organofluorines other than PFCAs, PFASAs and their major precursors, possibly including overlooked PFASs. In particular, perfluoroalkyl phosphonic and phosphinic acids (PFPA and PFPIAs) were recently detected at elevated levels in various matrices (e.g. surface water, indoor dust and food items). In this study, we conduct an extensive literature research with the aim to assess if these PFASs are potentially overlooked emerging contaminants (i.e. attributed with high hazards and exposure) and to highlight critical gaps in need of future research. A fair amount of information of PFPA and PFPIAs is retrieved, regarding their [i] physicochemical properties, [ii] PBT properties, [iii] production and use, [iv] possible emissions, and [v] occurrence in various matrices. A preliminary hazard assessment reveals evidence for concern, despite uncertainties due to limited data. For example, the primary use of PFPA and PFPIAs as defoamers in certain pesticide formulations can lead to immediate, direct exposure of users and the environment, but may also result in their accumulation in the environment due to likely high persistence. In addition, some PFPIA homologues are likely to be similarly bioaccumulative as PFOS and PFPA are likely less bioaccumulative than PFPIAs, but they may bind to blood cells and have a rather long half-life in humans. Furthermore, mixtures of PFPA and PFPIAs exhibited much higher toxicity to aquatic species than PFOA and PFOS, but may have a different mode-of-action from that of PFCAs and PFASAs. Currently, a thorough exposure assessment is ongoing to provide an overview of the environmental and human exposure to these substances.

### Acute and Chronic effects of Diltiazem to Fathead Minnow (*Pimephales promelas*) under Gradients of Dissolved Oxygen

G.N. Saari, S.P. Haddad, S.R. Burket, Baylor University / Environmental Science; K. Chambliss, Baylor University; J. Corrales, Baylor University / Environmental Science; B.W. Brooks, Baylor University / Dept of Environmental Science  
Water resources in arid to semi-arid regions of the United States are stressed by population growth and drought. Such changes influence contaminant and water chemistry dynamics in urban inland waters where flows can be dominated by or even dependent on wastewater treatment plant discharges. In these urbanizing watersheds, fish are exposed to interacting stressors such as contaminants of emerging concern (e.g., pharmaceuticals) and hypoxia that result in adverse outcomes to individuals and populations. Under the Clean Water Act in the USA, States are required to set water quality standards and criteria (WQC) to protect designated uses and specifically dissolved oxygen (DO) due to the increased frequency of hypoxia worldwide and its harmful impacts on aquatic organisms. 3 mg/L represents US Environmental Protection Agency recommendations to protect aquatic life stages other than early life stages from > 50% growth/production impairment and acute mortality. Additionally, 3 mg/L represents WQC for DO

subcategory high aquatic life use, commonly assigned to water bodies in Texas, where 24-hour DO minimum are not to extend beyond 8 hours. Recent field observations from our group identified diltiazem, a vasodilator used to treat high blood pressure, in fish plasma exceeding human therapeutic doses (e.g., C<sub>max</sub>). Therapeutic hazard values (THV) can be used to predict water concentrations expected to cause human drug therapeutic plasma concentrations in fish. The question of stressor mixture effects was highlighted as a major research needs to understand risks of pharmaceuticals in the environment. Therefore, the primary objective of the present study was to determine whether diltiazem differentially affected juvenile *Pimephales promelas* across DO gradients associated with common WQC in streams and lakes. Diltiazem toxicity increased under decreasing DO treatment levels (e.g., DO 8.24 mg/L LC<sub>50</sub> = 35.9 mg/L; -DO 3.00 mg/L LC<sub>50</sub> = 9.52 mg/L) with similar trends observed in heart rates and behavior. No adverse effects were observed on juvenile *Pimephales promelas* at the diltiazem THV value. Our findings indicate that laboratory studies performed at elevated DO concentrations underestimate environmental hazards of diltiazem to fish exposed to low DO levels, including current WQC values in the USA.

#### Reconnaissance of contaminants in larval Pacific lamprey (*Entosphenus tridentatus*) tissues and habitat in the Columbia River Basin, Oregon and Washington, USA

E.B. Nilsen, US Geological Survey / ORWSC; W. Temple, U.S. Geological Survey; B. McIlraith, Columbia River Inter-Tribal Fish Commission  
Pacific lampreys (*Entosphenus tridentatus*) have resided in the Columbia River Basin for many centuries and have great ecological and cultural importance. The role of habitat contamination in recent declines of the species has rarely been studied and was the main objective of this effort. A wide range of contaminants (115 compounds) was measured in sediments and tissues at 27 sites across a large geographic area of diverse land use. This is the largest dataset of contaminants in habitat and tissues of Pacific lamprey in North America is the first study to compare contaminant bioburden during the larval life stage and the anadromous, adult portion of the life cycle. Bioaccumulation of pesticides, flame retardants, and mercury was observed at many sites. Based on available guidance, contaminants are accumulating in larval Pacific lamprey at levels that are detrimental to organism health and could be contributing to declines of the species.

Jones, University of Saskatchewan / School of Environment and Sustainability; h. peng, Toxicology Centre; B. Sarauer, University of Saskatchewan / Toxicology Centre; K.B. Steeves, Toxicology Centre / Toxicology Centre; S.B. Wiseman, University of Saskatchewan / Toxicology Centre

In recent decades, national and international governments have established approaches and regulatory frameworks to assess the risks posed by endocrine-disrupting chemicals (EDCs). Despite global efforts towards establishing standard test strategies and decision-making criteria for monitoring and assessing sources of EDCs to the environment, effluents from wastewater treatment plants (WWTPs) have remained one of the most predominant sources of EDCs to the environment. Given the potential environmental issues resulting from exposure to EDCs and other emerging contaminants downstream of WWTPs, the aim of this project was to establish and validate a screening and prioritization approach ("toolbox") to characterize and assess potential effects of municipal effluents (MWEs) to biota in aquatic ecosystems. This was accomplished through a tiered screening approach that involved a combination of bioassay directed analysis and analytical chemistry in junction with *in situ* and laboratory studies with fish to characterize the potential ecological risks posed by emerging contaminants contained in these effluents. Two WWTPs in Saskatchewan, Canada (Cities of Regina and Saskatoon) that utilize different levels of treatment were investigated. Influent to both WWTPs had significant endocrine activities, with different degrees of amelioration of the observed effects in the effluents as a function of the wastewater treatment process. Furthermore, reproductive functions of fish collected from receiving water bodies or exposed in the laboratory to dilutions of the effluents were significantly impaired. Based on the preliminary data obtained to date the approach featured in this project allowed for characterization and differentiation among MWEs as a source of EDCs to surface waters that may explain biological effects observed in resident fish populations. Successful validation of this "toolbox" will help calibrate a set of common technologies that will be useful in context with characterizing and prioritizing testing of municipal effluents while reducing uncertainty.

#### Ecotoxicity testing and risk assessment of pollutants singly and in complex mixtures using bioluminescent cyanobacterial bioreporters

F. Fernandez-Piñas, Universidad Autónoma de Madrid / Biology; K. Martin-Betancor, M. González-Pleiter, J. Hurtado-Gallego, Universidad Autónoma de Madrid; F. Leganes, I. Rodea-Palomares, Universidad Autónoma de Madrid / Biology

A bioreporter is a transgenic organism carrying a transcriptional fusion between a sensing element (a gene promoter responsive to the stress or chemical to be detected) and a promoterless reporter system encoding quantifiable output signals (i.e. luminescence). Bioreporters complement analytical chemistry methods by providing information on the bioavailable fraction of the pollutants; they are cost-effective and rapid biological test systems. Cyanobacteria are ecologically relevant organisms especially well suited to study ecological impacts of emerging pollutants in aqueous systems, particularly wastewaters. We are constructing a battery of self-luminescent cyanobacterial bioreporters able to monitor the global toxicity of environmental samples as well as others able to detect specific pollutants. Strain *Anabaena* CPB4337 has been used to study the toxicity of priority and emerging pollutants singly and in complex mixtures [1]. It has been found that the nature of the interaction (synergism or antagonism) changes with effect levels and that the synergism found at low effect levels may imply a negative impact in aquatic ecosystems [1]; in a study with a mixture of antibiotics, we have found that certain specific combinations of antibiotics may pose a potential ecological risk with the present measured concentrations in wastewaters [2]. The strain has been found to be highly sensitive in environmental matrices such as wastewaters from municipal and industrial sources [1,3]. Strains *Synechococcus* pBG2120 and *Anabaena* pBG2154 respond to metals and pollutants provoking oxidative stress, respectively. The cyanobacterial bioreporters are useful tools to detect both general toxicity as well as specific pollutants in environmental samples including wastewater. #### Evaluation of cross-contamination of residual emerging contaminants and multi-drug resistant bacteria in lettuce crops irrigated with wastewater treated by sunlight/H2O2

G. Ferro, Civil Engineering; M. Polo-López, Plataforma Solar de Almería-CIEMAT; A. Martínez, University of Almería / Department of Chemistry and Physics; P. Fernández-Ibáñez, Plataforma Solar de Almería-CIEMAT; A. Agüero, University of Almería / Department of Chemistry and Physics; L. Rizzo, University of Salerno / Civil Engineering

Among different options to face water scarcity, wastewater reuse is gaining more attention, although it is considered globally as the most critical element of sustainable water management. Potential environmental and human health risks may rise because of the presence of emerging contaminants (ECs) and resistant (MDR) microorganisms which are not completely removed by conventional treatments. Still present in the treated effluents at very low concentrations, their release into the environment may pose serious risks when reused for crop irrigations. So far neither uniform criteria to assess environmental and human health risks nor quality criteria to safeguard the reuse practise are available. In this work crops' uptake of three ECs, namely carbamazepine (CBZ), flumequine (FLU) and thiabendazole (TBZ), and two MDR strains, namely ampicillin-, ciprofloxacin- and ofloxacin- resistant *E. coli* and ampicillin-, ciprofloxacin- and tetracycline-resistant *E. faecalis*, have been investigated. ECs (100 mg L<sup>-1</sup>) have been spiked and MDR strains (10<sup>5</sup> CFU mL<sup>-1</sup>) have been inoculated in real urban wastewater effluent which were undergone to a H<sub>2</sub>O<sub>2</sub>/sunlight process in compound parabolic collectors. Treated wastewater were collected after 5 h (R1) and 90 min (R2) and used as irrigation water for lettuce leaves transplanted in plant pots. Weekly analyses were carried out in order to assess the potential uptake of ECs and MDR strains both in lettuce leaves and in top soil. After 5 weeks of irrigation with R1 treated effluent, an accumulation of CBZ (374 ng g<sup>-1</sup> on soil and 48 ng g<sup>-1</sup> on lettuce) and of TBZ (121 ng g<sup>-1</sup> on soil and 11 ng g<sup>-1</sup> on lettuce) was observed. A higher accumulation for both ECs was observed when less treated wastewater was used as irrigation water. A presence/absence detection method was developed to assess the potential transmission of the selected MDR strains both in lettuce and top soil. The absence of both strains on all lettuce leaves and top soil samples after irrigation with disinfected effluents (5 h of treatment) confirmed an improved safety of irrigation practise. 90 min were not enough to keep out a potential transmission of pathogens on crops (MDR *E. faecalis* presence in 1 out of 15 lettuce samples and MDR *E. coli* presence in 1 out of 15 top soil samples). The present work, through an innovative experimental design, aims at giving a contribution to the enhancement of sustainable wastewater management and reuse.

664

#### Uptake, translocation and detoxification mechanisms induced by four selected

## pharmaceutically active compounds in hydroponically cultured alfalfa (*Medicago sativa* L.) plants

A. Christou, Agricultural Research Institute / Soil Science; C. Antoniou, Cyprus University of Technology / Department of Agricultural Sciences Biotechnology and Food Science; E. Hapeshi, University of Cyprus / NIREAS International Water Research Center; C. Christodoulou, Cyprus University of Technology / Department of Agricultural Sciences Biotechnology and Food Science; C. Michael, D. Fatta-Kassinos, University of Cyprus / Nireas International Water Research Center; V. Fotopoulos, Cyprus University of Technology / Department of Agricultural Sciences Biotechnology and Food Science

Pharmaceutically active compounds (PhACs) have been lately identified as abiotic stress factors in cultivated crops. In this study, a hydroponic experiment was employed in order to explore the uptake and translocation, as well as the abiotic stress responses and detoxification mechanisms induced by the exposure of alfalfa (*Medicago sativa* L.), a cultivated forage crop, to four selected PhACs (10  $\mu\text{g L}^{-1}$ ) (diclofenac, DF; sulphamethoxazole, SMX; trimethoprim, TMP; and 17 $\alpha$ -ethynylestradiol, 17 $\alpha$ EEL) and their mixture (MIX). Towards this objective, a combined biochemical and molecular approach was employed. Lipid peroxidation levels, estimated by *malondialdehyde* (MDA) content, revealed that exposure to each PhAC resulted in increased cellular damage only in roots, which were exacerbated as a result of exposure to the mixture of PhACs. Leaf proline content was similar in all treatments, whereas it significantly decreased in roots of plants exposed to DF, SMX and TMP, indicating that damage in roots was likely not due to osmotic effects. Hydrogen peroxide ( $\text{H}_2\text{O}_2$ ) was found to be accumulated in higher amounts in leaves rather than roots, as a result of PhACs exposure, whereas nitric oxide (NO) content followed an opposite trend, indicating a systemic action and crosstalk between the two active molecules for regulating signal transduction and stress responses. Enzymatic activity of catalase (CAT) and superoxide dismutase (SOD), as well as nitrate reductase (NR), provided biochemical support to the quantified  $\text{H}_2\text{O}_2$  and NO levels. The total antioxidant capacity of root extracts was increased as a result of plant exposure to each PhACs, reaching the highest level in the MIX treatment, correlating with MDA content in roots. Quantitative qRT-PCR gene expression analysis revealed that PhACs treatments is linked with increased transcript levels of glutathione S-transferase (*GST7*, *GST17*), proton pump (*H<sup>+</sup>-ATPase*) and cytochrome C oxidase (*CytCox*), indicative of detoxification mechanisms, as well as their supportive apparatus (e.g. mitochondrial respiration, sustained electrochemical gradient) induced in order for the plant to overcome the stress effects sustained. In addition, key antioxidant enzyme (*FeSOD*, *CuZnSOD*) gene expression was up-regulated in roots, supporting the mechanisms employed to overcome the cellular damage induced by the exposure of plants to the studied PhACs.

## Irrigation of vegetables with treated wastewater: Understanding uptake of pharmaceuticals and evaluating risks

B. Chefetz, T. Malchi, M. Goldstein, The Hebrew University of Jerusalem / Soil and Water Sciences; Y. Maor, Phytol Ltd. / Water and Soil Sciences Center of Excellence Environmental Health; G. Tadmor, The Hebrew University of Jerusalem / Soil and Water Sciences; M. Shenker, The Hebrew University of Jerusalem / Soil and Water

The use of treated wastewater for irrigation water is on the rise worldwide and is not limited to arid zones. Considering the ubiquity of PCs in treated wastewater (TWW), it is highly important to evaluate their fate and their uptake by crops under commercial agriculture conditions. The objective of this study was to investigate uptake of PCs by vegetables in greenhouse, lysimeters and commercial farming. PCs exhibiting a wide range of physico-chemical properties were studied in crops irrigated with TWW. In addition, a risk assessment associated with the consumption of TWW irrigated crops was conducted based on the threshold of toxicological concern (TTC) approach. Two root crops, carrot (*Daucus carota*) and sweet potato (*Ipomoea batatas*) were grown in lysimeters containing three different soils and irrigated with fresh water or TWW. In greenhouse experiments, tomato (*Solanum lycopersicum*), cucumber (*Cucumis sativus*) and lettuce (*Lactuca sativa*) were grown in pots containing three different soils with different properties. To ensure exposure, 14 different PCs were added to the TWW in the irrigation line during the growing period at environmentally relevant concentrations. In addition, a treatment in which non spiked TWW was used in order to study indigenous levels of PC exposure. Nonionic PCs were detected at significantly higher concentrations than ionic PCs in all leaf, root and soil samples. PCs that were taken up by the plants exhibited significantly higher concentrations in leaves than in roots. Two metabolites of carbamazepine were identified and quantified in soil and plant organs. The metabolite 10,11-epoxycarbamazepine was detected in all root, leaf and soil samples. In the soil and roots, the parent compound was dominant. In contrast, the concentrations of 10,11-epoxycarbamazepine in the leaves of carrots and sweet potatoes were significantly higher than that of the parent compound. The health risks associated with PCs in crops were assessed using the TTC approach. The TTC values for potentially genotoxic 10,11-epoxycarbamazepine and lamotrigine, for a child (25 kg) are 62.5 ng/day. The TTC level of lamotrigine is surpassed for a child (25 kg) by consuming half a carrot a day (60 g carrot/day). The TTC level of 10,11-epoxycarbamazepine are surpassed for a child (25 kg) by consuming 90 g leaves sweet potato/day and 25 g leaves carrot /day. Consumption above the TTC value is an indication that specific toxicity analysis of the PC is

required.

## Is biochar soil amendment an appropriate strategy to control the bioaccessibility of organic microcontaminants to crops?

C. Hurtado, IDAEA CSIC; J. Comas, N. Cañameras, ESAB-UPC; J.M. Bayona, Environmental Chemistry

Biochar is a predominantly stable, recalcitrant organic carbon (C), created when organic rich waste (e.g. biomass, manure, sludges) is heated to high temperatures, under a low oxygen atmosphere. Because its slow C turnover in the environment, the application of biochar to agriculture has been proposed as an strategy to mitigate the climate change with additional advantages to improve the soil fertility depending on soil pH and organic matter content. Moreover, depending on biochar physical-chemical properties, it behaves as an effective adsorbent for trace metals and organic microcontaminants from soil and water. Sorption experiments of organic emerging organic contaminants in biochar and biochar amended soils were performed in order to evaluate its sequestration potential and its capability to reduce the uptake of organic contaminants by crops from the irrigation water. A batch experiment was designed in order to study the effect of biochar addition. Equilibration time was set at 48 h. Then, the supernatants were percolated through Strata-X SPE cartridges Recovered extracts (5  $\mu\text{L}$ ) were injected into a Bruker 450-GC gas chromatograph coupled to a Bruker 320-MS triple quadrupole mass spectrometer. Qualitative and quantitative analysis were performed based on retention time and multiple reaction monitoring (MRM) mode of two product ions, and their ratio. The partitioning coefficients ( $K_d$ ) of the selected emerging contaminants in biochar, sand and agricultural soil are presented in shows a high sorption potential in biochar from its  $K_d$  value (>370 L/Kg). Moreover, when soils are amended with 2% (w/w) of biochar, most of the contaminants show a significant enhancement in their  $K_d$  value in respect to the non amended soil ( $p < 0.05$ ). The uptake of organic contaminants by crops depends on the physical-chemical properties of contaminant, concentration and soil. The application of biochar in soil decreases the contaminant concentration in the pore water and therefore their accessibility to plants. According with uptake studies at different concentrations, the uptake rate correlates with the soil concentration [8]. This work demonstrate the high  $K_d$  values of biochar for emerging organic contaminants of different  $K_{ow}$  values. The application of biochar in soils at 2% decreases also the pore water concentration which presumably decrease the accessibility of organic contaminants by crops irrigated with contaminated waters.  $\square$

## Emerging Contaminants in the Marine Environment: Presence, Effects, Regulation (II)

### Effects of environmental $\beta$ -blockers on fish glucose metabolism: testing the "Read Across Hypothesis" through a dynamic perfusion of isolated eel hepatocytes

E. Fabbri, University of Bologna / Bigea Department via Selmi Bologna; S. Franzellitti, University of Bologna / Interdepartment Centre for Environmental Sciences Research CIRSA; A. Kiwan, University of Bologna / CIRSA via S Alberto Ravenna

The impact of environmental pharmaceuticals is focus of intense investigation aimed at assessing the potential risk to human and ecosystem. Bearing in mind that pharmaceuticals are designed to have specific effects at low concentrations, several approaches have been proposed to identify pharmaceuticals of highest concern. According to the biological "Read-Across Hypothesis" a drug may have an effect in non-target animal species if molecular targets are evolutionarily conserved, and the pharmacological effect takes place only if plasma concentrations reached in non-target species are similar to human therapeutic concentrations. Because chemical safety data are greatly available for pharmaceuticals the biological "Read-Across Hypothesis" appears particularly promising, nevertheless it needs further scientific support.  $\beta$ -blockers are widely found as contaminants of the aquatic environment.  $\beta$ -adrenergic receptors (AR) have a crucial role in the regulation of lipid and glucose metabolism of fish. The present investigation aimed at evaluating the effects of propranolol (PROP,  $\beta$ -AR antagonist) and atenolol (ATE,  $\beta_1$ -AR antagonist) on glucose release from hepatocytes of the European eel. Freshly isolated hepatocytes were suspended in resin columns and perfused with Hanks' solution containing epinephrine (EPI) for 15 min. PROP and ATE were applied for a total of 45 min, starting 15 min before the hormonal treatment and continuing thereafter. Drugs were used at concentrations found in fish plasma in previous reports. Glucose release was measured in fractions collected every five minutes for 2 hours. EPI-induced glucose release was significantly reduced by PROP, and to a lower extent by ATE. PROP effect was dose-dependent, reaching a maximum inhibition (90%) at 1.1  $\mu\text{M}$ . EPI-induced glucose release was reduced by about 40% at 30 nM PROP, a concentration well below the therapeutic dose. The release was slightly but consistently reduced also by 2.4 nM PROP, a concentration calculated to occur in fish plasma after exposure to environmental concentrations of PROP. Present data confirm that PROP and ATE bind to conserved molecular targets and are active at therapeutically relevant doses, and that PROP affects fish EPI-induced glucose release at concentrations below the therapeutic doses for humans. The "Read Across Hypothesis" seems therefore not applicable to all

pharmaceuticals, depending on chemical properties and affinity for the specific targets.

668

#### **Predicted and measured concentrations of venlafaxine and its metabolites in a coastal zone receiving treated wastewaters**

L. Arpin-Pont, UMR Hydrosociences / UMR Hydrosociences Montpellier; A. Piram, Université Aix-Marseille / Département de Chimie de l'Environnement; D. Munaron, A. Fiandrino, IFREMER / Laboratoire Environnement et Ressources du Languedoc-Roussillon; M. Martinez-Bueno, Université Montpellier / UMR Hydrosociences Montpellier; O. Mathieu, CHU Montpellier / Département de Pharmacologie Médicale et Toxicologie Hôpital Lapeyronie; E. Gomez, Université de Montpellier, CNRS - Hydrosociences Montpellier UMR 5569 / Sc Environnement Sante Publique; H. Fenet, UMR 5569 Hydrosociences, Université Montpellier 1

Pharmaceuticals enter into the environment mainly after therapeutic use. Parent compounds and metabolites excreted in wastewater are inconstantly eliminated in WTPs and therefore are rejected mainly in surface water. However, the coastal environment suffers from pollution generated by inland activities which discharge their wastes into the sea via streams, rivers and wastewater marine outfalls. The low levels reported in the marine environment encourage the development of adapted methodologies to estimate predicted environmental concentrations (PECs). In the present work, the occurrence of VLF and its major human metabolites was investigated at a Mediterranean coastal site directly impacted by a submarine outfall. Concentrations of VLF and its metabolites were measured in the different compartments i.e. in water with passive sampler, sediment and mussels. Predicted concentrations of VLF and its main human metabolites were estimated in seawater taking into account the sold amounts of VLF, its human metabolism and the diffusion and dilution of the compounds in the coastal zone using an adapted hydrodynamic model (MARS 3D) developed by Ifremer. In seawater, estimated concentrations were in a good agreement with measured levels. Moreover, concentrations in mussels were estimated using concentrations estimated in seawater and a bioconcentration factor (BCF) linear model described in the literature for marine mussels. Estimated concentrations in biota were then compared to the concentrations in mussels detected at the studied site. Concentrations estimated with the BCF model were overestimated compared to measured concentrations, which could be explained by a possible metabolism of these compounds by mussels, not taken into account in the estimations. Moreover, attenuation mechanisms such as sorption on suspended matter could explain a lower availability of compounds for mussels in the water column and a lower bioconcentration in organisms than those expected. Studies on sorption mechanisms and metabolism of these compounds in mussels should be further performed, in order to improve these estimations. As organisms are long-term exposed to low concentrations of pharmaceuticals, possible effects could be observed. The use of sensitive approaches, such as "omics" approaches, already used for other pollutants such as heavy metals, could help obtain this information.

669

#### **THE EMBRYOTOXIC AND GENOTOXIC EFFECTS OF WIDELY USED BETA BLOCKERS ON SEA URCHIN (*Paracentrotus lividus*) EMBRYOS**

M.A. Karaaslan, University of Ege; H. Parlak, . Akal Arslan, M. Boyacıoğlu, Ege University

Pharmaceutically active compounds have attracted great attention last decades because of their potential environmental affects (Oetken et al., 2005; Zuccato et al., 2006; Działowski et al., 2006 and Triebkorn et al., 2007). Beside the expected impacts, depends on the concentrations of pharmaceuticals, unexpected side effects also can be occurred like failure in reproduction or change in genome structure. In our study the effects of Atenolol, propranolol, metoprolol and nadolol are being investigated by embryos of sea urchin *Paracentrotus lividus* which is one of important member of aquatic ecosystems. For this purpose we exposed sea urchin embryos to the selected beta blockers in order to find out embryotoxic, genotoxic and cytotoxic effects of them. According to our results the EC<sub>50</sub> values of embryotoxicity are 0,232 mg/l for Propranolol; 9,32 mg/l for Metoprolol, 33,802 mg/l for Atenolol and 53,08mg/l for Nadolol. Also we detect some chromosomal abnormality like mitotic bridge and scattered formations. Considering all the results obtained from tested beta blockers we can concluded that beta blockers have effects on embryonic development of sea urchin and these effects can be seen on embryonic stages, larval development and cytotoxic level.

670

#### **Toxicity, Bioaccumulation and Biotransformation of Silver Nanoparticles in Marine Organisms**

H. Wang, University of Massachusetts / Plan, Soil and Insect Sciences; K.T. Ho, U.S. EPA / Atlantic Ecology Division; K. Scheckel, US EPA; F.F. Wu, State Key Laboratory of Environmental Criteria and Risk Assessment; M.G. Cantwell, Atlantic Ecology Division; D.R. Katz, US EPA / Atlantic Ecology Division; D.B. Horowitz, U.S. EPA, ORD, NHEERL / Atlantic Ecology Division; W.S. Boothman, U.S. EPA / Atlantic Ecology Division National Health and Environmental Effects Research Laboratory Office of Research and Development; R.M. Burgess, U.S. EPA / Atlantic Ecology Division

The toxicity, bioaccumulation and biotransformation of citrate and polyvinylpyrrolidone (PVP) coated silver nanoparticles (NPs) (AgNP-citrate and

AgNP-PVP) in marine organisms via marine sediment exposure was investigated. Results from 7-d sediment toxicity tests indicate that AgNP-citrate and AgNP-PVP did not exhibit toxicity to the amphipod (*Ampelisca abdita*) or mysid (*Americamysis bahia*) at Ag<sub>2</sub>S (32-42%) > Ag metal (Ag<sup>0</sup>) (3-11%). In *N. virens*, AgCl (25-59%) and Ag<sub>2</sub>S (10-31%) were generally decreased and, Ag metal (32-44%) increased, relative to the sediments. The patterns of speciation in the worm were different depending upon the coating of the AgNP and both types of AgNPs were different than the AgNO<sub>3</sub> salt. These results show that the AgNP surface capping agents influenced Ag uptake, biotransformation and/or excretion. To our knowledge, this is the first demonstration of the bioaccumulation and speciation of AgNPs in a marine organism (*N. virens*).

671

#### **Gaps and needs in the implementation of MSFD Descriptor 8: the selection of an appropriate core set of contaminants for monitoring**

V. Tornøer; G. Hanke, Institute for Environment and Sustainability - Joint Research Centre

The Marine Strategy Framework Directive (MSFD) is the policy framework for protection of the European Seas. The input of contaminants into the marine environment is considered under MSFD descriptor 8 as one of the anthropogenic pressures which needs to be assessed by EU Member States. By 2012, the first substantial steps in the implementation of the directive were taken, including the preparation of the first phase of the national marine strategies, i.e. Initial Assessment, Determination of Good Environmental Status (GES), and Setting Environmental Targets and Indicators. The European Commission Joint Research Centre (EC JRC) in-depth assessment of the Member State's submissions for the MSFD and the subsequent discussions within the MSFD Expert Network on Contaminants have allowed the identification of gaps and needs regarding the MSFD implementation. The main identified contaminant-related issues are the selection of the chemical pollutants and best matrices for monitoring and the quantitative criteria for GES assessment. Moreover, the importance of designing monitoring programs compatible and integrated with the EU Water Framework Directive (WFD) and Regional Sea Conventions (RSCs) has also been stressed, along with the need to cover open and deep sea areas in an appropriate, representative and efficient way. These results can help to make suggestions for improvement in the next phase of MSFD implementation. For example, it has been suggested that harmonization within the EU might be improved by selecting an appropriate core set of contaminants of concern and ensuring they are well covered and monitored by all countries. While land-based issues shall be tackled by the WFD, the marine environment needs, within the MSFD, provisions which go beyond the WFD. Additional sources of information on pollutants in the marine environment should therefore be exploited, and quality standards and monitoring approaches made more consistent. Hence, the EC JRC is compiling information on all chemical contaminants which are released at sea and can potentially cause harm to the marine wildlife, in particular emerging pollutants which derive from new or growing human activities. These include e.g. shipping, resource exploitation, aquaculture and historical dumping. This information would complement efforts done under the WFD and so, support the establishment of an appropriate and consistent coastal to open sea framework for MSFD Descriptor 8 implementation across Europe.

#### **Distribution of organophosphate flame retardants in Mediterranean common dolphin tissues**

G. Santín, IDAEA-CSIC / Environmental Chemistry; C. Corcellas, IDAEA / Department of Environmental Chemistry; J. Gimenez, R. de Stephanis, Estación Biológica de Doñana (CSIC) / Department of Conservation Biology; E. Eljarrat, IDAEA-CSIC / Department of Environmental Chemistry; D. Barcelo, IQAB-CSIC / Institute for Environmental Assessment and Water Research

**Abstract** Flame retardants (FRs) are widely used to increase the fire resistance of materials. Due to the ban of polybrominated diphenyl ethers by the Stockholm convention in 2009, the FRs industry has been using other families of FRs, such as organophosphate FRs (OPFRs). These OPFRs are used in a wide variety of materials as FRs and also as plasticizer, which finally end up in the aquatic ecosystems contaminating sediments as well as biota. OPFRs can cause a delayed neuropathy, which can lead to irreversible paralysis. Besides neurotoxicity, OPFRs are also known for being endocrine disruptors and carcinogenic. OPFRs have been found in environmental samples (indoor air, house dust, drinking water, river water and sediment) as well as in some biota (fish, mussels and bird eggs) and human samples to date. There are not enough data to conclude a specific way of bioaccumulation. The purpose of this study is to assess for the first time the occurrence and levels of 16 OPFRs in common dolphin samples from Alboran Sea (Spain). Moreover, the distribution of OPFRs in different dolphin tissues (blubber, muscle, liver, brain and kidney) is investigated. OPFRs were detected in all samples. Total OPFR concentrations were between not quantified (NQ) to 24.7 µg/g lw. Thirteen out of sixteen tested analytes were detected. Only V6, TDCPP and TBNPP were not detected, and TEHP was detected but at levels below the limit of quantification. The highest concentration levels were obtained for IPPP, IDPP, TCPP and TPhP. As regards the detection frequency, TBEP was the most frequent compound, with 88% detection frequency, followed by TBP. The most contaminated sample was a brain tissue in which IDPP was reached a concentration

of 18.3 µg/g lw. The most contaminated tissue in terms of total OPFR concentration is blubber, with a median concentration of 127 ng/g dw. This means that these compounds apparently have the same bioaccumulation behavior as other FRs such as PBDEs. The next most contaminated tissue was muscle, followed by brain, kidney and finally liver. **Keyword:** organophosphorus flame retardants, marine ecosystem, common dolphins. Track and session: F - Identification and prioritization of emerging contaminants. Emerging Contaminants in the Marine Environment: Presence, Effects, Regulation. Presentation preference: **platform**

## Assessing the exposome: Prioritization, biomonitoring, modeling and experimental assessment of exposure factors (II)

### Incorporation of antimony and copper in pregnant women from traffic pollution

**M. Fort;** J.O. Grimalt, Environmental Chemistry; X. Querol, Institute of Environmental Assessment and Water Research IDAEA-CSIC; J. Sunyer, Centre for Research in Environmental Epidemiology  
The concentrations of antimony (Sb) and copper (Cu) in urine samples of 466 pregnant women from an urban area (Sabadell, Catalonia, Spain) have been studied. The geometric mean levels of Sb and Cu were 0.28 and 13 µg/g creatinine, respectively. Positive associations between urine concentrations of Sb in pregnant women and traffic density at their home streets have been observed. This metal is a common component of brake linings being present in the urban atmospheric particles as consequence of vehicular use. Cu is also an important component of brake linings but no significant association between road traffic and urine concentrations was found. This lack of association is probably due to the regular presence of traces of this metal in food which constitutes an additional input in women. Positive associations between urine Sb concentrations and maternal physical activity have been observed which may respond to higher intake of this element by inhalation of urban atmospheric particles. Higher concentrations of Sb and Cu were found in the maternal urine samples collected in winter which may reflect a higher degree of urban atmospheric pollution by higher particle re-suspension and lower dispersion due to stable thermal inversion episodes during dry and cold periods. These results identify traffic as a specific source of Sb exposure for human populations and, specifically, pregnant women. Part of the Cu intake could also be contributed from traffic but in the context of the diverse Cu inputs in the Sabadell cohort this source could not be identified with statistically significance. In any case, the reported results evidence a potential exposure to Sb of children during the fetal growth in mothers living near streets with heavy traffic. To the best of our knowledge, this is the first study considering the associations between human exposure to this metal and traffic pollution.

### Mass spectrometric strategies for targeted and non-targeted exploration of the exposome

**M. Lamoree;** VU University, Institute for Environmental Studies / Institute for Environmental Studies  
In the past decades, Effect-Directed Analysis (EDA) – in which chemical analytical techniques are combined with (in vitro) bioassays to identify environmental contaminants capable of causing adverse effects – has developed into a promising tool for investigative monitoring that can also be applied to explore the exposome of e.g. wildlife. During our studies, expertise was gained for the identification of environmental contaminants in various matrices using high resolution mass spectrometry, but we realized that dedicated compound databases including chemicals that could be encountered in the environment under study, such as house dust, would aid the identification process to a great extent. Horizon scanning provides useful information about compounds to which we are exposed in daily life, facilitating their identification in exposure media like house dust or human matrices. For further exploration of the exposome, the identification of unknown compounds may be complemented by the use of targeted mass spectrometric strategies for the trace level quantification of known emerging contaminants and their metabolites, delivering data that can be used for further in-depth epidemiological studies. Reliable information regarding – often low – levels of toxicants in human matrices obtained by cohort analysis enables the assessment of the impact of these compounds on human health. In addition, targeted and non-targeted metabolomics approaches were developed for mapping the biological consequences of exposure to specific environmental contaminants, as a follow-up of the exposomics work. In this presentation, the above approaches for the study of the exposome from multiple angles will be discussed in more detail and examples will be given to demonstrate their suitability.

### Neutral loss screening of mercapturic acids - compensating matrix effects by post column infusion

**R. Bloch;** Helmholtz Centre for Environmental Research GmbH / UFZ; M. Plassmann, Department of applied environmental science; W. Brack, M. Krauss, Helmholtz centre for environmental research - UFZ / Effect Directed Analysis

One of the major challenges for modern medicine is the prevention and treatment of so-called civilization diseases such as dementia or allergies. The impact of the genome on these diseases is considered rather low. Consequently, the environmental impact on our health has to be investigated. The daily uptake of chemicals by polluted air, water, and food, as well as the application of cosmetics and pharmaceuticals, causes electrophilic stress in the human body, which might result in diseases. In this study, we characterized the electrophilic burden by analysing mercapturic acids (MA), the breakdown products of glutathione conjugates. We established an untargeted neutral loss screening method for the analysis of MA in human urine using direct injection liquid chromatography – tandem mass spectrometry (LC-MS/MS). Because urine is a very complex and diverse matrix, there is a high variation in ionization behaviour within and between different samples. This results in poor comparability of samples and distortion of signal intensities. Therefore, matrix effects were monitored by constant post column infusion of an isotope-labelled standard, making it possible to compensate intra- and inter-sample deviations in ion suppression. We analysed 20 urine samples of pregnant women considering their exposure to tobacco smoke. By applying post column infusion, matrix effect profiles were recorded and used to standardize the different samples. Several compounds could be tentatively identified using a suspect compound search. However, no discrimination of samples according to cotinine concentrations was observed. This could be due to the low number of subjects and alternative nicotine uptake pathways. Nevertheless, the high diversity of the individual MA profiles is an indication for the multiplicity of possible risk factors. In conclusion, both MA screening and matrix compensation are promising tools for the evaluation of human exposure to chemicals and the identification of so far unknown, but potentially harmful compounds.

### The dynamics of the human contaminants cocktail: Employing longitudinal POPs data from Northern Norway (1979-2007) and mechanistic models

**T.M. Sandanger,** UiT The Arctic University of Norway / departement of community medicine; **T.H. Nøst,** NILU Norwegian Institute for Air Research / MILK; **J. Odland,** University of TromsÅ; **K. Breivik,** Norwegian Inst. for Air Research  
Humans are continuously exposed to a substantial number of contaminants, and no study can capture the overall complexity. The present work has summarized the time trends across almost thirty years for 24 polychlorinated biphenyls (PCBs), 17 organochlorine pesticides including metabolites (OCPs), 3 polybrominated diphenyl ethers (PBDEs), and 10 per- and polyfluoroalkyl substances (PFASs) in a set of persons. These trends were based on analyses of serum sampled from 53 men in Northern Norway in 1979, 1986, 1994, 2001, and 2007. DDTs decreased from 1979, many PCBs from 1986 whereas PBDEs were low throughout and PFASs increased until 2001 and decreased thereafter. The compositional patterns changed according to the trends yet PFASs were dominant in most years. Based on these results, the understanding of temporal aspects of human concentrations can provide a holistic view on human exposure to contaminants in terms of complexity and dynamics. A close resemblance could be observed between human concentrations and the overall global emission estimates for the different compound groups. Also, emission-based environmental and human accumulation modeling could reproduce temporal trends for PCBs and the age group patterns observed in measurements. Predicting individual PCB concentrations in two cross-sectional studies including pregnant and postmenopausal women displayed realistic concentrations compared to measurements. Predicting concentrations previous in their life course revealed temporal aspects providing valuable illustrations of variation over time in PCB concentrations within and between individuals. In the longitudinal study, the time trends were specific to the different compound groups and the diverging changes likely largely relate to different production and use histories along with environmental and human persistence. These perspectives clearly show the close relation between use and concentrations and have implications for considerations of human exposure. **Keywords:** POPs, mechanistic models, emissions, cocktail

### Modeling the exposure history of human individuals to persistent organic pollutants

**F. Wania,** University of Toronto at Scarborough / Department of Physical and Environmental Sciences; **M.J. Binnington,** UTSC - Dept. Physical & Environmental Sciences / Physical Environmental Sciences; **S.A. Wood,** J.M. Armitage, University of Toronto - Scarborough / Department of Physical and Environmental Sciences; **T.H. Nost,** NILU Norwegian Institute for Air Research; **K. Breivik,** Norwegian Inst. for Air Research  
Combined environmental fate and food chain bioaccumulation models provide the capability to simulate, through a fully mechanistic description of the relevant thermodynamic and kinetic processes, a persistent organic pollutant (POP)'s journey from release into the environment to its accumulation in humans. Non-steady-state models allowing time-variant simulations covering periods of multiple decades have been used to estimate the average exposure history of different population cohorts to POPs. Such assessments may then serve as a complement to empirical biomonitoring studies evaluating a population's exposure to POPs. It is of substantial interest to identify sources of variability in the measured human concentrations. Biomonitoring studies often obtain additional information on the sampled individuals through questionnaires. Collected data generally include

age at sampling, date of sampling, gender, body mass index, number of children and age at birth, breastfeeding habits, and detailed dietary composition. While such data can be used to find statistical associations between measured contaminant exposures and potential influential factors, statistical analyses cannot identify causal relationships and provide ultimately no mechanistic understanding of the processes underlying human POP exposure. However, the same questionnaire responses can also be used to individualize the parameterization of the human in mechanistic exposure models. In other words, instead of only calculating average population exposure, the models can be used to simulate the distinct exposure histories of all sampled human participants individually. Here we present the results of three studies simulating the exposure of individuals to polychlorinated biphenyls (PCBs) using the environmental fate and bioaccumulation model CoZMoMan or similar model combinations. The models generally succeed in predicting population average exposure. Also the range of predicted PCB exposures generally agrees with the range of measured exposures. Trends with key variables, such as BMI and age, were mostly similar for the measured and simulated concentration data. However, in two studies the models attributed more of the variability in PCB exposure to inter-individual differences in dietary composition than a statistical analysis of the measured data would support. The measured data indicated that there were other sources of variability not currently accounted for in the models.

#### **Cleaning Product Ingredient Safety Initiative: Product-Type-Specific Exposure Assessment**

S. Williams, Baylor University; M.C. Ciarlo, EA Engineering, Science, and Technology; C. Horne, EA Engineering, Science, and Technology / Water and Natural Resources; B. Greggs, Soleil Consulting; P.C. DeLeo, American Cleaning Institute; B.W. Brooks, Baylor University / Dept of Environmental Science  
The Cleaning Product Ingredient Safety Initiative (CPISI) is a multi-year effort to conduct a screening-level risk assessment for all identified chemical ingredients in the consumer cleaning products manufactured by the member companies of the American Cleaning Institute (ACI). One objective of the CPISI was to calculate deterministic estimates of intake for each cleaning product through each possible exposure route. The base requirements for the estimates are 1) the concentration at the point of exposure, 2) the frequency and duration of product use, 3) the amount used, 4) the body weight of the exposed individual, and 5) route-specific parameters (respirable fraction, skin contact area, etc.). In this exercise, only intended uses of the products were considered. To establish concentrations of ingredients in the products, we revisited data gathered earlier in the program, and also gathered formulation information (i.e., frame formulas) for each product type from trade literature, company surveys, and other resources. Ranges of concentrations for each ingredient in each product within the scope of the CPISI were gathered, in the context of its functional use class (FC). Other exposure parameters were collected from previous efforts on habits and practices conducted by the American Cleaning Institute, and from additional resources such as EPA's Exposure Factors Handbook and the Human and Environmental Risk Assessment for Cleaning Products. Estimates of exposure were calculated and incorporated into a database, and when ingredients were used in multiple product types, estimates of aggregate exposure were also developed and integrated. This effort has culminated in development of a database which links cleaning products to their respective types to ingredients and ingredient functional use classes (FC) to relevant exposure models and ultimately to an upper-bound point estimate of intake under typical conditions of product use. This database will be available through ACI's Science portal. Future efforts will compare these exposure estimates to safety values for each ingredient. Should the margin of exposure exceed an acceptable threshold, refinement of the exposure estimates may become necessary. Numerous opportunities exist for refinement of these exposure estimates, including re-examination of ingredient concentrations and use patterns for each product.

#### **Effect Modelling of environmental systems - extrapolation and prediction of species response (II)**

679

#### **Benefits of ecological modelling for risk assessors**

M. Wang, WSC Scientific GmbH / Dept Efat Modelling

While population modeling and other mechanistic modelling approaches are used occasionally as a higher tier risk assessments of chemicals, these methods are not yet fully integrated into the present risk assessment scheme. This is partly due to the fact that population models are complex and not easy to understand by non-experts, but it is also due to concerns regarding the reliability and realism of population models. For example, it is often stated that there are large uncertainties in complex population models and that some data needed to address a specific risk may not be available. We therefore evaluate the uncertainties and the realism involved in standard risk assessments and show how many of them can be addressed using modelling. We show which benefits models offer to risk assessors, particularly for reducing uncertainties included in standard risk assessments. While all data used in standard risk assessment are also included in population-level risk assessments, much more additionally data are usually considered in the latter. In addition, effects can be studied in greater depth, determining which ecological or toxicological factors mainly influence the risk for a particular species and under which

conditions/scenarios a risk may occur. Safety factors are used in standard risk assessment, which may or may not be large enough to cover uncertainties and natural variability. However, modeling approaches are often fully probabilistic, ensuring that even rare events (e.g. particularly high exposure in few animals or effects in years with very unfavorable weather conditions) can be studied. The comparison of population-level risk assessments vs. standard risk assessments shows how risk assessors can greatly benefit from using models to reduce uncertainties of standard risk assessments by taking all our knowledge of a species into account instead of focusing only on exposure and toxicity.

680

#### **Modelling effects of variable herbicide exposure to terrestrial plant communities in field boundaries**

J. Reeg; T. Schäd, EnSA; K. Körner, University of Potsdam; A. Solga, Ecology; T.G. Preuss, Bayer CropScience / Environmental Modelling; F. Jeltsch, University of Potsdam

Plant communities of field boundaries are potentially impacted by herbicide exposure due to drift. The intensity of exposures varies e.g. due to wind and application. Risk assessments aim to evaluate the impact on plant communities. With respect to ecotoxicological testing, guidelines (OECD, US EPA) define experiments on individual species. They do not take interactions of individuals within or amongst species into account. Especially these intra- and interspecific interactions influence plant community dynamics. By linking a landscape-scale exposure model (Xplicit) to a mechanistic plant community model (IBC-grass), we simulate the effect of variable herbicide exposure on herbaceous plant communities neighbouring treated fields. IBC-grass is an individual-based plant community model for grasslands using the trait-based plant functional type (PFT) approach to cover a wide range of species characteristics. Based on an extensive literature research, we compiled a list of herbaceous plant species typically forming field boundary communities in Europe. According to that, IBC-grass was parameterized and the regional species pool classified into PFTs. Due to the individual-based approach of IBC-grass, we were able to transfer individual-level risk effects (as a species effect distribution; Xplicit) to PFT individuals within IBC-grass. Exposure effects were simulated on local patches of 3 m<sup>2</sup> along a distance gradient from the crop field. Species effect distributions were generated by Xplicit. On community level, effects on functional diversity and richness as well as on biomass were analyzed. On population level within the community context, effects on population size, biomass and the recovery potential were studied. Close to the field edge, simulated PFTs showed - besides short-term direct effects - also long-term indirect effects in the community context that are related to interactions between individuals. Variable exposure showed that years of low herbicidal disturbance have the potential to reduce long-term effects. Applying our model approach makes it possible to upscale from individual herbicide effects to community responses. Including variable herbicide exposure adds more realism to our mechanistic model approach at landscape-scales. Thereby, potential future assessment endpoints can be addressed.

681

#### **Coupling aquatic IBMs and ecosystem models to interpolate effects from the laboratory to the field**

T. Strauss, Research Institute gaiac / Research Institute Gaiac; F. Gabsi, Rifcon GmbH; M. Hammers-Wirtz, Research Institute gaiac; P. Thorbek, Syngenta / Environmental Safety; T.G. Preuss, Bayer CropScience / Environmental Modelling  
For the application of mechanistic population models in ecological risk assessment, an important question is still under debate: Which level of complexity is needed for a realistic and accurate description of population dynamics? In this study, we combine a laboratory individual-based population model (IBM) for *D. magna* (IDamP) and a complex stoichiometric lake model (StoLaM), to create the DaLaM (*Daphnia* Lake Model). We used DaLaM to predict population dynamics of two ecotoxicologically relevant laboratory test organisms, *D. magna* and the green alga *Desmodesmus subspicatus*, under realistic field conditions. In DaLaM, the variable environmental conditions such as light, temperature, and nutrient cycling are realistically simulated. Also for the population dynamics of both planktonic species, we integrate a high number of biological processes, but we deliberately and drastically simplify the community complexity including only two trophic levels and two species. For model testing, we used data from several aquatic mesocosm studies lasting several months, and from a 2-year mesocosm study including two winter seasons. Our aim is to demonstrate the predictive power of detailed models in which the parameterization of the different biological processes was based on laboratory experiments, for extrapolating from individuals in the laboratory to populations in the field. We will show DaLaM's ability to predict the overall population pattern of phytoplankton and daphnids in the mesocosms, indicating that the essential mechanisms and main drivers of the system have been included in the present modeling approach. Also the possibility to simulate direct and indirect effects on the *Daphnia*-phytoplankton interactions for scenarios using insecticides as well as herbicides, will be discussed.

682

#### **A new modeling approach for population level risk assessment of lagomorphs**

J. Kleinmann, WSC Scientific GmbH; M. Wang, WSC Scientific GmbH / Dept Efat Modelling

Plant protection products are indispensable for modern agriculture and contribute to food quality and quantity, but they imply a risk to non target organisms and populations, which makes a reliable risk assessment a huge challenge for science and industry. Models can represent a good and in some cases the only practical method, e.g. when evaluating the effects of multiple stressors, for risk assessment. To evaluate these effects and extrapolate risk, e.g. between species or compounds, a population model for lagomorphs is used. We developed a new procedure for spatial movement of individuals, which provides model output that is methodologically very close to field data. Home range sizes of individuals are not directly calibrated, but emerge from the sum of movement decisions of individuals. This very flexible approach makes it possible to simulate intraday spatial movements and field like home range behaviour for mammals. In the first part of the analysis we show that simulated spatial movement of animals is reproduced realistically and matches observations from field studies. Also resulting home range sizes are shown to be realistically simulated. Methodological differences of different field studies, like varying home range calculation periods, are recreated using a virtual observe perspective. In the risk assessment of chemicals the portion of time foraging (PT) in different habitats is an important factor determining exposure. Our model is able to predict these values. After a detailed validation of the model, effects by multiple stressors are analyzed in different landscapes and with different scenarios. It is shown how landscape structure affects the resulting effects, which are related to home range size and spatial dispersal movements. Furthermore, it is shown, how the properties of different compounds (e.g. dose response) used in agriculture affect populations in a landscape specific way. Population models offer a suitable tool to study effects of multiple stressors, like different pesticides, habitat or seasonal survival rates and agricultural practice. With the proposed approach a new level of detail, including intraday movements, and spatial behavior can be obtained. This method helps to understand and detect processes relevant for population dynamics, brings new possibilities for model validation and directly simulates PT-values for all habitats in the simulated landscape which makes it a helpful tool for risk assessment.

#### **Comparative external validation of common aquatic toxicity prediction tools: Informing selection and development of tools for alternatives assessment.**

F. Melnikov, Forestry and Environmental Studies; A. Voutchkova-Kostal, George Washington University / Chemistry; J. Kosal, Sustainability AZ; J.L. Tunkel, SRC, Inc. / Environmental Health Analysis; P. Anastas, Yale University / Center for Green Chemistry and Green Engineering; J. Zimmerman, Yale University  
Alternatives toxicity assessments often necessitate the filling of experimental data gaps with predictive models. Since aquatic toxicity is a typically a required and fundamental criterion for assessing hazard, a number of predictive tools have been developed by regulatory agencies (US EPA), academia, and the private sector. Most methods estimate acute and chronic aquatic toxicity via Quantitative Structure Activity Relationships, while a few rely on property-based design guidelines. However, predictive ability of the available, computerized methods has not been compared in the last decade. Authors have experience developing a range of toxicity models based on molecular fragments, modeled electrochemical properties, nuclear magnetic resonance spectra, and electronic parameters determined from quantum mechanics calculations. The goal of the collaborative, interdisciplinary assessment was to compare, evaluate, and validate predictive tools and guidelines for aquatic toxicity. We identified a data set distinct from the training sets of all freely available QSAR tools, some proprietary software, and the most recently property-based design guidelines developed by the authors. The results are based on two data sets of 306 and 286 chemicals and aquatic toxicity measurements isolated from ECHA and ECOTOX database, respectively. Using these data sets, we evaluated the predictive power and applicability domains of the aforementioned methods. The experimental data was combined with physical and reactivity parameters to identify types of chemicals with highest error rates and margins. The results elucidate best application practices in green chemistry and regulatory assessments, and expound opportunities for the development of *in silico* aquatic toxicity prediction tools.

### **Addressing data collection and computational challenges in LCI (II)**

684

#### **The importance of going beyond standard LCI databases: Lessons from a Meta-Analysis of Potable Water Supply System LCAs**

N. Meron, The Porter School of Environmental Studies; G. Thoma, University of Arkansas / Department of Chemical Engineering; V. Blass, Tel-Aviv University / The Recanati Graduate School of Business Administration; Y. Garb, Ben-Gurion University of the Negev / Blaustein Institutes for Desert Studies Social Studies Unit

The life cycle assessments (LCAs) for an overwhelming portion of products and services must draw on estimates of the environmental impacts of potable water. Close to a hundred LCAs have been published characterizing the impacts of water supply systems, however, the great diversity of the systems and their location yield a diversity of LCA results. Thus, in the absence of localized Life Cycle Inventories (LCIs), most analyses draw their impact figures for water from one of a few

standard life cycle inventories, whose applicability to a given local case is uncertain. This has led for a call for increased harmonization of LCA efforts to allow comparison and pooling of results. Here we describe a comprehensive and rigorous review of LCAs of water-supply systems and sub-systems, which allows us to better understand the sources of variation in these studies, and identify those elements of the water-supply system with the consistently highest environmental impacts. This review utilized a systematic differentiation of the subsystems, functional units, and system boundaries referenced in each of over 100 candidate studies to produce a comparable subset of 34 LCA studies. Next, statistical techniques (cluster analysis and analysis of means) were used to isolate and validate the main causes of variation and the sub-systems in which these are most pronounced. It shows the presence or absence of desalination (and thermal desalination in particular) as an overwhelming determinant of the environmental impacts of water supply systems, with other factors in a secondary role. Our results show the importance of LCA that goes beyond standard LCI databases to consider the local contexts of water production, and points the way to doing so without conducting a localized analysis in each case. Given the large variation we describe in the impacts of water supply systems (from 0.2 to 3.4 Kg CO<sub>2</sub>-eq/m<sup>3</sup> of supplied water), a LCA of water-intensive products drawing from a standard LCI databases could be inaccurate in many settings, especially in a region with desalination--an uncertainty that can be reduced considerably by taking this into account.

685

#### **Temporally disaggregated data for the life cycle assessment of services provided by ICT**

T. Dandres, CIRAIIG; E. Maurice, CIRAIIG - École Polytechnique de Montréal / Chemistry; K. Nguyen, Synchromedia École de Technologie Supérieure; Y. Lemieux, Ericsson Canada; M. Cheriet, Synchromedia École de Technologie Supérieure; R. Samson, Ecole Polytechnique de Montreal / Department of Chemical Engineering

The proper functioning of the modern society relies increasingly on information and communication technologies (ICT). However, despite that ICT have some positive effects on the society, they also have impacts on the environment. Indeed, it was estimated in 2007 that ICT contributed to 2% of the global anthropogenic greenhouse gas (GHG) emissions, the same amount that the aviation sector. Therefore, many efforts are being made to lower the overall environmental footprint of ICT. The life cycle assessment (LCA) could be a good candidate for that purpose, but it faces several methodological challenges. In this study, the focus is made on electricity modeling in the LCA of ICT. Indeed, both the electricity generation by power plants and the electricity demand by ICT usually vary all the time independently. However, these temporal phenomena are commonly neglected in LCA. To improve the LCA methodology, a dynamic LCA approach based on temporally disaggregated data, has been used to model environmental impacts attributed to the electricity consumption of data centers in different regions of Canada. Additionally, a dynamic consequential LCA approach has been developed to minimize in real time, the GHG emissions of two data centers working in cloud computing. Results show that an LCA based on annual aggregated data would underestimate by 10% the GHG emissions of the data centers during the use phase when compared to the dynamic LCA using real-time data. Regarding the real-time GHG emissions minimization of the cloud computing: the dynamic consequential LCA allows for a reduction of 35% of the cloud computing GHG emissions when compared to the conventional LCA. The results obtained in this project highlight that temporal aspects should not be neglected by default when studying dynamic ICT systems. With the emergence of ICT, it becomes pertinent to consider regional and temporal aspects of both generation and consumption of electricity in LCA and carbon footprint assessment. Moreover, the case of systems optimized in real-time thanks to ICT is problematic since the current methodologies are not able to compute the reduction of GHG emissions achieved by the smart management of electricity in such systems. Therefore, there is a need to update the current LCA and carbon footprint guidelines for the ICT sector. It should be recommended to use regional temporally disaggregated data to evaluate ICT when ICT power demand and regional electricity generation vary over time.

#### **Indoor air quality impacts in a regional energy conservation district: Life cycle model and baseline data collection**

M.M. Bilec, W.O. Collinge, University of Pittsburgh / Civil and Environmental Engineering

The potential of green buildings to significantly improve occupant health and productivity while mitigating the effects of anthropogenic climate change and reducing energy use remains unclear. However, many initiatives have proceeded to set aggressive energy and greenhouse gas emission reduction strategies. We have introduced the term Energy Conservation Districts (ECDs) to describe such initiatives which are taking place in a specific geographic area on the order of a city neighborhood or business district. In this research we are conducting an indoor air quality (IAQ) pilot study to establish baseline IAQ conditions and associated human health and productivity impacts in an ECD located in Pittsburgh, PA, USA. Factors influencing energy use in buildings, such as ventilation and envelope modifications, can influence IAQ directly, while indirect effects may be linked to geographically co-located energy supply and transport processes. We outline a geographically specific LCA model coupling building energy use models with both

direct and indirect life cycle impacts, showing how proposed energy savings measures could influence IAQ. The Use-Tox life cycle impact assessment (LCIA) model is used as a source of effect factors, while exposure assessment is assessed with a modified indoor-outdoor compartment model compatible with Use-Tox. We also outline a protocol for data collection to establish baseline IAQ conditions within the subject ECD. The baseline data will be used to generate an existing conditions LCA model which can be adapted to simulate proposed energy use reduction measures.

#### **Uncertainty and sensitivity analyses in LCA: a review and application to noise characterization**

E. Igos, CRP Henri Tudor / Resource Centre for Environmental Technologies CRTE; R. Meyer, Public Research Centre Henri Tudor / Resource Centre for Environmental Technologies CRTE; E. Benetto, CRP Henri Tudor / Resource Centre for Environmental Technologies CRTE; F. Querini, Resource Centre for Environmental Technologies CRTE; A. Marvuglia, Luxembourg Institute of Science and Technology (LIST) / Resource Centre for Environmental Technologies CRTE; Resource Centre for Environmental Technologies CRTE; C. Beaudard, Campus LyonTech La Doua

In the common practice, Life Cycle Assessment (LCA) studies regularly include sensitivity analyses, but based on simple approaches and often limit uncertainty analysis to Monte Carlo (MC). This work aims at highlighting the challenges of uncertainty/sensitivity analyses related to data collection (uncertainty characterization) and to computation (propagation methods and tools). The application of the available methods to car tire noise characterization will identify their limitations and added values. The most applied uncertainty propagation method, MC analysis, can be improved by considering correlations, Latin Hypercube or Bayesian MC approach. A few LCA studies explored the use of fuzzy intervals which require less information. Hybrid method samples both on probability and possibility distributions. Finally, analytical methods calculate the variance of the inventory matrix based on Taylor series expansion. Local sensitivity analysis (LSA) studies the effects of small inputs variations on the model output, by varying one parameter at the time (OAT), building scenarios or calculating derivatives. Global sensitivity analysis (GSA) explores the entire space of the inputs and calculates their influence and interaction/non-linearity effects (method of elementary effects or Fourier/Sobol variance decomposition). Noise characterization models were used to evaluate the potential benefits of a new car tire as compared to its base version and tested through uncertainty analysis (MC), LSA (OAT) and GSA (Sobol). Due to lack of data, several distributions for a key parameter were tested and led to different conclusions, which highlights the need of reliable and numerous data for statistical methods. LSA and GSA identified the same parameters which needed a better specification and GSA showed low influence of interaction effects. Statistical methods require a good knowledge on the input uncertainties, which was an obstacle for the tire noise results interpretation. Some approaches allowed characterizing uncertainty with little information and GSA quantifies the influence of parameters and the interaction effects for a better understanding of the model. However, these techniques often need the use of other software than the ones commonly used in LCA (e.g. Python language here). Further research regarding the case study will concern a better definition of key parameters identified from LSA and GSA, as well as the application of other uncertainty propagation methods.

688

#### **Key methodological issues of Organisation Environmental Footprint: insights from application in the agricultural machinery sector**

A. Zamagni, Ecoinnovazione / LCA and Ecodesign Laboratory; G. Garavini, Ecoinnovazione; P. Porta, P. Masoni, ENEA / LCA and Ecodesign Laboratory The Commission Recommendation of 9 April 2013, which follows the Communication "Single Market for Green Product", recommends Product and Organisation Environmental Footprint for the assessment and communication of the environmental footprint of products and organisations, respectively. While pilot tests are in progress under the coordination of DG Environment, an international Group, leader in the production of agricultural equipment for tillage, seeding, crop care, green maintenance and hay making, is implementing the OEF for its Italian production plants. Being one of the first applications of the OEF, many challenges arose, starting from the goal and scope definition. The purpose of the OEF study is twofold: i) identify the relevant environmental aspects related to all the activities of the organisation; ii) monitor the environmental performance improvements following technical and managerial interventions on productive plants. The main drivers of the organisation are both external and internal: to demonstrate the corporation engagement towards a continuous environmental improvement; to get useful insights to lower the overall impact of the organisation; to collect and manage data in a rational framework useful for the optimisation of the organisation management; to obtain data and indicators useful for a future sustainability report. The scope of the analysis includes all the organisation activities in 2012 and 2013 and the related product portfolio. The latter includes all the products manufactured by the organisation and commercialized with its own brand; products produced for other brands; products produced purchased and sold with the organisation brand; all the spare parts. The product portfolio count 23.563 different references in 2012 and 24.470 in 2013. Besides the huge number of products to be considered, the

challenges relate also to the mass balance between input and output of the organisation, which requires an evaluation of how to deal with stocks, and the variability of the organisation boundaries from year to year, as the organisation is growing with acquisition of new brands, production plants, and activities. This paper presents and discusses key methodological aspects of the OEF that came out from the application into the agricultural machinery sector, focussing in particular on the modelling of the product portfolio and on system boundary definition when a tracking performance approach is adopted.

## **Endocrine Disruptors: Exposure, Hazard & Risk Assessment (II)**

689

#### **Phase two of inter-laboratory validation of the *Xenopus* Embryonic Thyroid Signalling Assay**

S. Mothre, A. Sebillot, A.J. Tindall, Watchfrog S.A.; T. Iguchi, National Institute for Basic Biology / Molecular Environmental Endocrinology; K.W. Buchholz, Booz Allen Hamilton Inc. / Military HealthEnergy Environment; B. Demeneix, MNHN/CNRS; G.F. Lemkine, D. Du Pasquier, Watchfrog S.A. The *Xenopus* Embryonic Thyroid signalling Assay (XETA) was designed as a screening assay to provide information on the potential of a test substance to alter the normal functions of the thyroid system. The XETA provides a rapid (< 72h) way to measure the response of embryonic stage tadpoles to potential thyroid disrupting chemicals, allowing an efficient method for screening thyroid disruptors. In addition to serving as a quick screen for thyroid active chemicals, XETA, could serve as a potential alternative method to the *in vivo* Amphibian Metamorphosis Assay (AMA - OECD TG231). The AMA test is based on the study of the metamorphosis of tadpoles after three weeks of exposure to a given chemical, and includes histological examination of the thyroid gland. XETA could provide an alternative test that can be performed quickly, providing information that would be useful for screening large number of molecules or testing environmental samples that couldn't be stored or sampled in large quantities. The objective of the validation study is to establish the relevance of the assay by assessing its sensitivity to detect disruption of the thyroid system by compounds active at different points within the thyroid system. The validation is intended to determine the performance and transferability of the assay across a range of both experienced and naïve laboratories. XETA utilizes free-living *X. laevis* embryonic-stage animals (stage 45 up to stage 47) in a multi-well format to detect modulation of thyroid receptor signaling by potential thyroid active chemicals. The assay is transcriptional-based, and uses a transgenic tadpole line containing the THbZIP genetic construct to detect the activity of Thyroid active molecules that work through various mechanisms. The phase one ring test experiments gave the expected results for the chemicals chosen. A statistical approach was determined and a great consistency of the results was observed between laboratories. The XETA Phase I results demonstrate that the assay provides reasonable sensitivity with the chemicals tested and is reproducible, with a few exceptions, across replicates and labs. The XETA phase II will start early 2015 and active chemicals with modes of action that were not covered in phase I will be tested. In addition, several inert chemicals will be selected to challenge the assay and the statistical analysis procedure. The XETA protocol has been modified in accordance to lesson-learned during the phase one.

#### **Endocrine Disrupting Potential of Tebuconazole: a *Xenopus laevis* 27-day study**

R. Poulsen, University of Copenhagen / Department of Pharmacy; X. Luong, University of California Berkeley / Department of Integrative Biology; M. Hansen, University of California, Berkeley / Civil Environmental Engineering Integrative Biology; B. Styrisshave, Dep. of Pharmaceutics & Analytical Chemistry; T. Hayes, UC Berkeley / Integrative Biology Pesticides are used worldwide to reduce nuisances such as fungi, insects and weeds and thereby increase agricultural yield. The environmental dispersion of these agrochemicals has caused concern, as some are suspected of impairing immune function and interfering with the endocrine system in wildlife. Azole fungicides are a class of agrochemicals, which have shown high capacity for causing endocrine disruption. In this group we find tebuconazole, a chemical used in the production of cereals, fruits, and vegetables and as a preservative biocide. The heavy usage underlines the need to investigate the fate of the compound in the environment and its possible effects on ecosystems. Tebuconazole has been found in river water (up to 3.2 µg L<sup>-1</sup>), sediment (up to 600 µg/kg dry wt) and in whole body extracts from wild caught amphibians (363 ng/g wt). Existing literature indicates endocrine disruption by inhibition of the enzymes CYP17 and CYP19 in the steroidogenic pathway. A 27-day controlled exposure study of adult male *Xenopus laevis* was conducted to examine the mechanism by which tebuconazole may disrupt the steroidogenesis. Up to 12 different steroid hormones were measured using RIA and GC-MS/MS in blood samples collected 12 days into the study and at termination (day 27). This allowed for assessment of whether effects increased with exposure or adaptation to the xenobiotic occurred. After 12 days of exposure to 100 and 500 µg L<sup>-1</sup> tebuconazole, significantly increased levels of testosterone (TS) and dihydrotestosterone (DHT) and reduced concentrations of 17β-estradiol (bE2) were observed. Exposure to 0.10 µg L<sup>-1</sup> on the other hand resulted in decreased levels of

TS and DHT. After 27 days of exposure, no effects were observed in androgen levels while the effect on bE2 persisted. These results suggest that the hypothesized inhibition of CYP17 and CYP19 takes place, but with CYP17 inhibition being reversible and dominating at low concentrations while CYP19 inhibition dominates at higher concentrations. The CYP19-inhibiting potential of tebuconazole was confirmed in an *in vitro* enzyme assay and the action of the fungicide on CYP17 was further assessed by quantification of expression of CYP17 in gonads by RT-qPCR. Significantly increased transcription was observed in frogs exposed to 500 µg L<sup>-1</sup> and this may explain some of the observed adaptation to tebuconazole exposure. Moreover, we observed very high tissue specific bioconcentration factors (3.6

## 691

### Ligand affinity of the *Lymnaea stagnalis* estrogen and retinoid-X receptors (LsER and LsRXR): implications for detecting endocrine disruptors

A. Boulahtouf, IRCM Inserm U896 - Université Montpellier1; M. Grimaldi, IRCM, Institut de Recherche en Cancérologie de Montpellier, INSERM, U896; M. Coutellec, INRA / Ecology and Ecosystem Health UMR INRA Agrocampus Ouest; A. Besnard, INRA / UMR ESE 0985; Y. Echasseriau, INRA; W. Bourguet, CBS CNRS UMR5048 - INSERM U1054; P. Balaguer, INSERM U896 IRCM; L.L. Lagadic, Bayer CropScience / Environmental Safety

The freshwater gastropod *Lymnaea stagnalis* has been selected as a test species for the development of an OECD Guideline for reprotoxicity testing in molluscs. This *in vivo* test will appear as a Mollusc Partial Life-Cycle Assay at Level 4 of the OECD Conceptual Framework for Testing and Assessment of Endocrine Disruptors (EDs). However, in *L. stagnalis* as in other mollusc species, the existence, properties and ligand-affinity to ED-binding receptors are poorly documented and even controversial, so that the endocrine origin of adverse effects on individuals' reproduction cannot be ascertained. The present study was therefore designed to characterize the properties and ligand-affinity to ED-binding receptors of *L. stagnalis*. The genomic resources recently acquired in *L. stagnalis* and available for other molluscs were used to sequence LsER and LsRXR genes. Expression vectors of these genes were synthesized and used for transient cell transfection. Transactivation and binding tests were then performed with ligands known to bind human ER and RXR (HsER and HsRXR). In parallel, the ligand binding domains of LsER and LsRXR were modelled to characterize molecular interactions between LsER or LsRXR and the tested ligands. The results showed that LsER activity is constitutive and not mediated by known ligands of HsER, including estradiol, its natural ligand, and bisphenol A. In contrast, LsRXR can be activated by its natural ligand 9-cis-retinoic acid, and also by pharmaceutical (*e.g.*, CD3254) and environmental (*e.g.*, organotins) ligands. This *in vitro* approach will contribute to fill the knowledge gap on ED-binding receptors in molluscs and support interpretation of mechanisms underlying adverse reproductive effects of chemicals in *L. stagnalis* in the context of the forthcoming OECD Guideline.

## 692

### Linking high throughput screening data of chemicals and environmental mixtures to endocrine activity and sex organ deformities in experimental animals

B. van der Burg; B. van Vugt-Lussenburg, BioDetection Systems; B. Pieterse, BioDetection Systems BV; E. Simon, Centre Ecotox; P. Behnisch, BioDetection Systems; A. Brouwer, BioDetection Systems BV

We have a long standing history in developing and applying robust CALUX® reporter gene assays for chemical hazard identification, food-, feed-, water-, epidemiology and environmental monitoring. In the EU FP7 project ChemScreen we focused on the use of these models and complementary technologies to set up a broad high throughput screening system for endocrine disruptors and reproductive toxicants. The assays we used were highly selective for specific molecular pathways. This allowed more straightforward validation of the panel and linkage of its results via so-called adverse outcome pathways (AOPs) to test results in experimental animals. Using a mechanistic approach a high throughput panel of assays has been developed which can be used to predict endocrine activity of single chemicals and environmental mixtures. We showed that this mechanistic approach can also be used to validate assays and link them to adverse outcome pathways and thus adverse effects in experimental animals. In this way a closer link to current guideline tests can be made. Additional steps towards regulatory acceptance include validation and establishment of trigger values.

## 693

### Major contribution of bisphenol A to estrogenic activity in landfill leachate as revealed by effect-directed analysis

L. FUSTER, LPTC-EPOC, University of Bordeaux / UMR EPOC LPTC; L. MAZEAS, Irstea / Unité Hydrosystèmes et bioprocédés; K. LE MENACH, LPTC; A. GUENNE, Irstea Antony / Unité Hydrosystèmes et bioprocédés; M. Dévier, LPTC-EPOC, University of Bordeaux / Oceanic and Continental Environments and Palaeoenvironments; N. Creusot, INERIS; L. ROUILLAC, Irstea Antony / Unité Hydrosystèmes et bioprocédés; P. MAZELLIER, ANSES / Member of the Working Group; S. Ait-Aissa, INERIS / Ecotoxicology Unit; H. Budzinski, University of Bordeaux / UMR EPOC Equipe LPTC

Landfill leachates are contaminated by a wide diversity of organic compounds and especially by endocrine disrupting chemicals. These complex mixtures can be

leached into soils and groundwaters by advective transfer through holes or diffusion through geosynthetic liners and constitutes a risk for aquatic ecosystems. Because of complexity and variability of these matrices and the restricted number of molecules focused in targeted chemical analyses, selection of relevant molecules for environmental monitoring is often laborious. Effect-directed analysis combining fractionation step, with chemical and biological analyses might allow to identify the compounds responsible for observed effects. Investigations were conducted on an untreated leachate of municipal waste disposal. After a fractionation step by RP-HPLC, estrogenicity of crude extract and 40 fractions was assessed by *in vitro* bioassay on the reporter cell line MELN. An estrogenic activity (260 ng EQQ/L) was detected in raw extract of landfill leachate. In order to bring out estrogenic molecules not targeted by chemical analysis in the global extract, this extract was fractionated. Effect-directed analysis, used in this work, allows to identify bisphenol A as main contributor to estrogenic activity in this landfill leachate and brings to light the presence of polar estrogenic compounds. This method can be valuable to prioritize hazardous molecules in landfill leachates.

## 694

### Altered reproductive capacity of Japanese medaka exposed to maternally transferred TBCO

S.B. Wiseman, University of Saskatchewan / Toxicology Centre; J. SUN, Toxicology Centre; S. Tang, School of Environment and Sustainability; D.M. Saunders, University of Saskatchewan / Toxicology; h. peng, Toxicology Centre; M. Hecker, University of Saskatchewan / School of the Environment and Sustainability and Toxicology Centre; J.P. Giesy, University of Saskatchewan / Toxicology Center

Worldwide, great efforts are being made to assess risks of exposure to endocrine disrupting chemical (EDCs), a group of chemicals that can impair reproduction resulting in declines in populations of fishes. The brominated flame retardant (BFR), 1, 2, 5, 6-tetrabromocyclooctane (TBCO), is an EDC. Although most studies focus on effects of EDCs on sexually mature fishes, early-life stages of fishes, including embryos, respond to EDCs. However, little is known about long-term consequences of exposure that occur only during embryonic stages of development. Therefore, studies were conducted to determine effects of TBCO on 2 generations of Japanese medaka to investigate whether exposure only to maternally transferred TBCO affects reproductive capacity of adults. Fecundity of the F<sub>0</sub> generation exposed to TBCO through their diet was lesser by 18% compared to controls. Cumulative fecundity of F<sub>1</sub> adults given the TBCO through their diet but raised from embryos of F<sub>0</sub> adults given the control diet was lesser by 30% compared to fecundity of F<sub>1</sub> adults of the same lineage but given the control diet. However, fecundity of F<sub>1</sub> adults raised from embryos of F<sub>0</sub> adults given the diet of TBCO was only lesser by 8% compared to controls. Fertilization of eggs was not quantified in the F<sub>0</sub> generation. However, fertilization of eggs by F<sub>1</sub> generation exposed to TBCO via maternal transfer and that were given the diet of TBCO was lesser by 18% compared to fertilization of eggs by F<sub>1</sub> generation that were not exposed to TBCO via maternal transfer but were given the diet of TBCO. This suggests that exposure only to maternally deposited TBCO differentially affects reproductive performance of male and female fish. Mechanisms of effects are not known. Molecular responses of embryos to TBCO might confer greater tolerance to TBCO during reproduction. Results of transcriptomic and proteomic studies to elucidate effects of TBCO on embryos will be discussed. To begin to understand if there is an epigenetic basis to these effects the reproductive capacity of adults from embryos exposed to waterborne TBCO will be presented. Overall, results suggest that responses of embryos to maternally transferred TBCO are an important determinant of reproductive capacity of sexually mature fishes.

## Carbonaceous materials for contaminants remediation

## 695

### The sorption strength of neutral organic compounds to biochars: a novel remediation technique

S.E. Hale, Norwegian Geotechnical Institute / Environmental Engineering; H.H. Arp, NGI / Environmental Engineering; D. Kupryianchyk, Norwegian Geotechnical Inst.; G. Cornelissen, NGI

The sorption strength of neutral organic compounds to biochars was reviewed and subsequently related to biochar and compound properties. From 29 studies, 509 individual Freundlich sorption coefficients were compiled that covered the sorption strength of 107 organic contaminants to a broad array of biochars. Reported logarithms of these Freundlich sorption coefficients, log K<sub>Fr</sub> (µg/kg)(µg/L)<sup>-n</sup>, varied from 0.38 to 8.25 for the diverse compound classes, including pesticides, herbicides and insecticides (range of mean compound values 3.40 to 5.69), PAHs (range of mean compound values 5.26 to 7.16), phthalates (range of mean compound values 4.47 to 5.41), halogenated organics (range of mean compound values 4.49 to 6.38), small organics (range of mean compound values 3.14 to 4.18), alcohols (range of mean compound values 3.03 to 5.63), and PCBs (range of mean compound values 4.43 to 7.27). The correlation between log K<sub>Fr</sub> and dry-pyrolysis temperature (T (°C), r<sup>2</sup> = 0.36, n=349, p<0.001), biochar oxygen-to-carbon ratio (O/C, r<sup>2</sup> = 0.05, n=184, p=0.003), biochar hydrogen-to-carbon ratio (H/C, r<sup>2</sup> = 0.27, n=187, p<0.001), biochar surface area (SA (m<sup>2</sup>/g), r<sup>2</sup> = 0.32, n=477, p<0.001) and organic compound hydrophobicity (log K<sub>ow</sub>, r<sup>2</sup> = 0.18, n=509, p<0.001) were investigated.

The sorption strength of organic compounds to biochars increased with increasing biochar production temperature, biochar SA and organic pollutant hydrophobicity and decreased with biochar O/C ratio and biochar H/C ratio. A combination of these variables resulted in the following multiple parameter linear regression:  $\log K_{Fr} = (0.15 \pm 0.06) \log K_{ow} + (3.79 \pm 0.74) \log T + (0.75 \pm 0.15) \log SA + (1.74 \pm 0.28) \log OC + (-0.94 \pm 0.19) \log HC + (-6.53 \pm 1.67)$ ,  $r^2 = 0.62$ , root mean squared error = 0.94,  $n = 152$  and  $p < 0.001$ . This information can be used as an initial screening to identify biochars that are optimal for use as pollutant sequestering agents for the purpose of reducing the risk of organic pollutants in agricultural areas or the environment. Biochars produced at high temperatures are preferable as sequestering agents, with biochars produced at temperatures greater than 400 °C sorbing the most consistently. The choice of feedstock has a smaller effect on organic compound sorption affinity and thus the selection of a biomass material should primarily be based on logistics, such as abundance as a waste product and low transport costs.

#### ADSORPTION OF POLAR AND IONIC COMPOUNDS TO PYROGENIC CARBONACEOUS MATERIALS

J.J. Pignatello, Connecticut Agricultural Experiment Sta. / Environmental Sciences; F. Xiao, C. Lattao, The Connecticut Agricultural Experiment Station / Environmental Sciences

This talk will describe recent work on adsorption to pyrogenic carbonaceous materials (PCMs). It will emphasize polar and charged compounds, which have received much less attention than hydrophobic compounds, but have a colorful chemistry at PCM interfaces. It will go beyond traditional topics to include steric effects, pi-pi interactions, strong hydrogen bonding, competitive effects, organic matter fouling, and critical structural characteristics of the PCMs that govern sorption. The talk will also reveal one way in which modification of biochars can enhance sorption.

697

#### The power of power: Electrokinetic control of PAH interactions with exfoliated graphite

L.Y. Wick, Helmholtz Centre for Environmental Research UFZ / Environmental Microbiology; J. Qin, Helmholtz Center for Environmental Research UFZ / Environmental Microbiology; A.M. Moustafa, University of Alberta / Civil and Environmental Engineering; H. Harms, Helmholtz Centre for Environmental Research UFZ; M. Gamal El-Din, University of Alberta / Department of Civil and Environmental Engineering

Polycyclic aromatic hydrocarbons (PAH) are commonly found in natural and oil field produced waters. Without adequate treatment PAH contaminate the ecosystem and cause deleterious effects to ecosystem and human health. Various treatment approaches for process water have been developed including chemical modifications to adsorbents. Among them, exfoliated graphite (EG) has been attracting particular interest. Having a low density, a high surface area and wide pore size distribution of 2 nm to 10 µm, EG exhibits an exceptional sorption capacity for petroleum and its constituents. Due to its comparably high cost, however, novel approaches hybridizing sorption with physical and biological treatment approaches are needed. Here we use EG as a carbonaceous model sorbent in order to assess the effect of weak direct current (DC) electric fields on the EG sorption capacity for the PAH phenanthrene. When an electric field is applied to a matrix submersed in an ionic solution, it invokes electromigration, electrophoresis, and electroosmosis (EOF). EOF is the surface-induced movement of pore fluids in an electric field, usually from the anode toward the cathode. EOF is more efficient in fine-grained (with meso- and micropores) than in macroporous materials. The conductivity of fine-grained matrices for pressure-driven (e.g. hydraulic) liquid flow is extremely small and leads to quasi stagnant water in micro- and mesopores. Molecular diffusion hence is limiting both access of sorbates to and release of sorbates from such pores as potential sites of high sorptive capacity for sorbates. Hence, EG-filled micro-reactors were exposed to a weak DC in presence of PHE to challenge the hypothesis that DC-fields may lead to increased EOF-mediated PHE transport to poorly accessible EG sorption sites and to increased sorption rates and/or decreased desorption rates of as compared to DC-free controls. Our data confirm this hypothesis. They show that EOF leads to increased PHE entrapment in EG-pores and both, to tenfold increased sorption rates and > 99% reduced desorption rates in presence of DC. Such 'power of power' may allow for tailor-made regulation of the sorption/desorption kinetics of chemicals to/from carbonaceous sorbents e.g. in water treatment or in biotechnology to control the bioavailability of substrates to transforming microorganisms. Current studies using activated charcoal support our findings of EG.

698

#### Effects of activated carbon amendment on benthic organisms *Lumbriculus variegatus* and *Chironomus riparius* in PCB contaminated sediments in freshly amended and aged systems

L. Nybom, Department of Biology; S. Abel, University of Eastern Finland / Department of Biology; G.C. Waissi-Leinonen, University of Eastern Finland; K. Maenpää, University of Eastern Finland / Department of Biology; M.T. Leppanen, Finnish Environment Institute / Laboratory Centre; J.V. Kukkonen, University of Jyväskylä / Biological and Environmental Science; J. Akkanen, University of Eastern Finland / Department of Biology

Activated carbon (AC) amendments have been studied as a new stabilizing method for contaminated sediments. The sorption efficiency of AC toward hydrophobic organic compounds (HOCs) has been shown in several studies. Recently the focus has been turned also to the possible secondary effects of AC amendments. The result relating to secondary effects has been somewhat contradictory and especially sediment dwelling organisms has been shown to be sensitive to AC amendments. The aim of this study was to investigate the efficiency of AC to reduce bioaccumulated concentrations of PCBs and possible adverse effects on benthic organisms, main focus being on how long contact time affected the effects of AC amendments. *Lumbriculus variegatus* and *Chironomus riparius* were used as test organisms. Coal based AC (ø 63-200 µm) was mixed in natural sediments from PCB contaminated areas and let to stabilize for two weeks or three years after amendment. AC amendments proved to be efficient in reducing PCB bioaccumulation and the sorption capacity remained strong even after three years of AC-sediment contact time. However, adverse effects were observed on *L. variegatus* biomass and egestion both with two weeks and three years AC-sediment contact times. Reduction in *C. riparius* growth was observed in addition with indications of AC amendment related delay in emergence especially in the second generation midges in the experiments were AC-sediment contact time was two weeks. On the other hand low dose of AC (0.5% sediment dry weight) increased production of eggs in some of the studied sediments. Responses observed within this study emphasize the importance of site specific characterization when remediation measures are designed, by knowing the local conditions the applied doses may be adjusted to avoid secondary effects as far as possible. Sediment dwelling organisms may be sensitive to carbon amendment due to the exposure both internally and externally and thus they may also be suitable indicator species for the secondary effects of AC.

699

#### PCB reduction in fish after AC amendment to sediment

U. Ghosh, University of Maryland Baltimore County / Chemical Biochemical and Environmental Engineering; H. Fadaei Khoei, University of Maryland Baltimore County / Civil and Environmental Engineering; E.R. Patmont, University of Maryland Baltimore County / Chemical Biochemical and Environmental Engineering

While much work has been done demonstrating the effect of strong sorption of PCBs in sediments on bioaccumulation in benthic invertebrates, exposure to fish is less well understood. Black carbon in sediments present natively, or added as an amendment can greatly reduce porewater concentrations of PCBs, resulting in reduced flux from the sediment to overlying water and reduced bioaccumulation in benthic organisms. In the present study we performed laboratory aquaria experiments, modeling, and a full-scale remediation in a small lake, to explore how PCB sorption in sediments impacted exposure pathways and bioaccumulation in fish. Impacted sediments from a contaminated river treated with activated carbon to reduce bioavailability was used in the laboratory experiments along with untreated and control sediments. Laboratory results showed that porewater PCB concentration in impacted sediment was reduced by two orders of magnitude upon amendment with 4.5% powdered activated carbon. Sediment treatment reduced the PCB uptake in fish by 87% after 90 days. Freely dissolved concentrations in porewater and overlying water was measured by passive sampling and incorporated in equilibrium and kinetic bioaccumulation models for predicting uptake by fish. The fish exposed to untreated sediment did not reach equilibrium after 90 days of exposure in the laboratory. Uptake prediction with the kinetic model was generally within a factor of 2 compared to observed values for dominant PCB congeners. Our results indicate that by tracking changes in freely dissolved porewater and overlying water PCB concentrations, it is possible to predict effectiveness of sediment remediation in reducing PCB uptake in the food chain, including fish. The latest results from a full-scale field implementation of AC amendment to a 5-acre lake and food web monitoring will also be presented.

#### Sustainable olive oil production by effective utilization of olive mill wastes

A.G. Vlyssides, National Technical University of Athens; N. Van der Smitten, National Technical University of Athens / School of Chemical Engineering All olives' treatment processes (olives, olive oil, olive wooden residue) produce liquid and solid wastes, which are considered toxic. The treatment of these wastes

by using conventional technologies (aerobic/anaerobic biological treatment, incineration, gasification ect) proved to be neither technically nor cost effective. This fact treats the olive oil production by complete cease due to the serious environmental problems caused. The proposed technology includes the detoxification of wastewater by Fenton oxidation reactions and following their utilization by biological treatment methods. The latter is achieved by the implementation of anaerobic digestion process on the oxidized wastewater and the consequent methane production and by co-composting the oxidized or/and anaerobic digested wastewater with solid wastes (olive mill wooden residue, leaves, branches ect.), leading to the production of a high quality soil conditioner. The biogas produced could be utilized for in situ thermal and electrical energy production. The two biological processes used (anaerobic digestion and composting) are ideal combined, since the anaerobic digested wastewaters are totally used in composting process, while the excess thermal energy produced by biogas utilization can accelerate the aerobic biological processes resulting in a high quality biological fertilizer. The proposed technology is effective and simple to be implemented. Wastewaters derive either from two or three phase olive mill could be treated. This technology can be implemented either in one olive mill scale or in central wastewater treatment plants. The proposed technology can not only effectively face the serious environmental problems caused by olive mill wastewater disposal, but it poses new perspectives in olive trees cultivation and olive oil and its by-products market. The soil conditioner is produced exclusively from plants, and it has been proved to be ideal for the biological cultivation of many products such as citrus, vineyards, aromatic herbals, asparagus etc. Thus, it can make the biological olive trees cultivation effective, because the use of chemical fertilizers is totally eliminated and the economical profit perspective is promising, since the price of biological olive oil is 1,5 times higher than the respective price of the olive oil deriving from “chemical” cultivation. By the application of the proposed technique all the nutrients (K, P, N), which have been removed from the cultivation soil, could be recycled by using the produced biological fertilizer. By this way the sustainability of olive trees cultivation and of olive oil production renders feasible and the whole proposed technique proved to be effective and characterized as “clean” technology. This technology is already used by 4 olive mills in Greece with very promising results and can be a promising alternative either for all the olive mill owners or for olive trees and generally biological products cultivators.

##### ORAC as a biomarker of antioxidant defense

S. Furuhashi, Stockholm University / Department of Applied Environmental Science ITM; B. Liewenborg, Stockholm University / Department of applied environmental science; M. Breitholtz, Inst för tillämpad miljövetenskap / Department of Applied Environmental Science ITM; E. Gorokhova, Stockholm University / Department of Applied Environmental Science ITM  
The antioxidative system is vital for organisms to maintain their oxidative homeostasis and protect biomolecules from oxidative damages. In ecotoxicological studies, alterations in the antioxidant defense is often assessed by assaying the activity of individual antioxidative enzymes separately. However, it is difficult to make any overall conclusions about effects on the antioxidant defense from these results as the enzymes may react differently from each other. The activity of a few selected enzymes may not provide a complete picture of the antioxidant defense as this is a complex system consisting of multiple enzymes and non-enzymatic compounds with antioxidative properties. However, there are several assays that measure the total antioxidative capacity in samples. In this study we look at one of these assays, Oxygen Radical Absorption Capacity (ORAC), as a biomarker of antioxidant defense in ecotoxicological studies. This assay has successfully been used to measure the levels of antioxidants not only in food and beverage, but also in biological samples, such as blood and plasma. There are also recent studies that have applied ORAC in ecotoxicological studies with invertebrates. In this study, we aim to establish a dose-response curve from ORAC as well as examine the time-dependent response of this biomarker. We also study how ORAC relates to the activity of commonly assayed antioxidative enzymes (e.g. CAT, SOD) and levels of lipid peroxidation. These relations are important to establish to strengthen ORAC as a suitable biomarker in ecotoxicological studies and to facilitate the interpretation of the ORAC response.

#### MO002

##### Gene expression analysis of antioxidant responses in Annelids, Brassicaceae and Fabaceae exposed to cadmium and/or lead contaminated soils.

F. BERNARD, LSVF, University of Lille / Laboratoire des Sciences Végétales et Fongiques Faculté de Pharmacie; F. Brulle, Unité Expertise in Toxicology Ecotoxicology of Substances DRC VIVA ETES; S. Dumez, University Lille2 / Laboratory of plant and fungal sciences; S. Lemière, Fonctionnement des Ecosystèmes Anthropisés; A. Platel, Institut Pasteur de Lille / Laboratoire de Toxicologie; F. VANDENBULCKE, LGCgE, Université de Lille 1 / LGCgE EA Univ Lille Fonctionnement des Ecosystèmes Terrestres Anthropisés Cité Scientifique SN Rdc F Villeneuve d'Ascq France  
Pollutants, such as Metal Trace Elements (MTEs) and organic compounds (polycyclic aromatic hydrocarbons, pesticides), can impact DNA structure of living organisms and thus generate DNA damage. Animal or vegetal cells use antioxidant defense systems to protect themselves against Reactive Oxygen Species (ROS) produced during oxidative stress. The mechanisms of production and management of ROS were investigated a lot in ecotoxicology as unspecific markers. We performed a literature survey of the biochemical responses (enzyme activities) and expression variations of genes encoding proteins involved and/or related to antioxidant response in three species that are often used in ecotoxicology and that live in close contact with soil: the earthworm, *Eisenia fetida*, the white clover, *Trifolium repens* and the cabbage, *Brassica oleracea*. Literature survey and data search in molecular database were carried out on the basis of keywords in Scopus, in PubMed and in Genbank™ for each species (and in related species). In literature, some antioxidant enzyme activities have already been measured in those species but such analysis do not allow distinction of individual enzyme involvements in oxidative stress. Gene expression studies would allow this distinction at the transcriptomic level. By exploiting the conservation observed between species and using molecular biology techniques, we partially cloned and measured the gene expression of many candidates involved and/or related to antioxidant responses in *E. fetida*, *T. repens* and *B. oleracea*. Therefore, analysis of the gene expression level of most effectors involved and/or related to antioxidant responses has been performed in the 3 species exposed *in vivo* (3, 10 and 56 days) in a well-characterised sub-urban reference soil spiked with cadmium and/or lead at environmental concentrations. The use of gene expression analysis (in combination with metal accumulation analysis) has shown the interest of studying the effects of metal stress in several species. A major interest of this work lies in the measurement of most genes involved and/or related to antioxidant response at the same time and in several species. Indeed, as responses to oxidative stress may be different between species for the same protein family, one may keep in mind that model species should be used in a complementary manner in order to better understand the effects of xenobiotics on exposed organisms.

#### MO003

##### The DNA damaging antibiotic Zeocin affects cell cycle progression in green algae *S. quadricauda* and *C. reinhardtii*

m. saenz, W.D. Di Marzio, Universidad Nacional de Lujan-CONICET; S. Curieses; K. Bišová, Laboratory of Cell Cycles of Algae Institute of Microbiology  
The release of genotoxic chemicals in natural ecosystems has an impact on mutation frequency, leading to modifications of genetic pools of wild populations. These adverse effects could alter cell cycles, affecting size of populations and growth patterns and finally ecosystem sustainability. Both biochemical and physiological changes as well as modifications in DNA integrity, produced by an exposure to organic pollutants, are utilized as an early signal of alarm of potential degradation of ecosystems. These biomarkers allow the identification of adverse effects, which if they continue, a breakage in normal homeostasis processes can occur, inducing irreversible damage leading to the death of organisms and disappearance of populations. Among aquatic organism, microalgae have an important role in aquatic system as they are a key component of food chains. So that, it is crucial to have early assessment tools to evaluate genotoxic effects at the cellular level, which can lead to disturbance in structure and productivity of the algae community. In the present study effects of Zeocin, a DNA damage mimetic antibiotic, were evaluated on cell cycle progression and regulation as well as modifications on antioxidant enzymes kinetic of two green algae dividing by multiple fission. Synchronized algal cultures were used for the study. Aliquot from growing cultures were taken hourly during 36 hours. The attainment of commitment points (CP) was evaluated by transferring hourly aliquot into aerated tubes at 30 °C in the dark. In hourly samples analysis of cellular division, nuclear division (DAPI stain) changes in cell size, protein, kinase activity and antioxidant enzymes activities of catalase, guaiacol peroxidase, ascorbate peroxidase and glutathione reductase were performed. The proportion of mother cells, daughter cells (*Chlamydomonas* sp.), number of nucleos, 4, 8 celled daughter coenobia (*Scenedesmus* sp.) were assessed at the end of the cell cycle. Zeocin provoked a block of the next G2 phase. Cells only attained one CP, all further CP were abolished. Nuclei showed abnormal shapes. Assayed parameters in Zeocin treated cells were higher compared to untreated ones. Implications of genotoxic agents on algal cell growth, cell cycle and population performance in natural environment are discussed, as well as development of cell biomarkers to predict impact at population level.

#### MO004

##### Effects of atmospheric benzene exposures on plants

S. Dumez, University Lille2 / Laboratory of plant and fungal sciences; F. BERNARD, LGCgE, Université de Lille 1 / Laboratoire des Sciences Végétales et Fongiques; S. Germain, University of Lille; L. Soubigou-Taconnat, INRA URGV; A. Garat, University of Lille; S. Balzergue, INRA URGV; B. Hanoune, CNRS Université Lille; D. Cuny, University of Lille 2  
Benzene is an indoor and outdoor atmospheric pollutant belonging to the VOCs (Volatile organic compounds) and classified as a class I carcinogenic by the International Agency for Research on Cancer. If the monitoring of these compound emissions is essential, the benzene automatic measurement methods on the field are not today enough efficient or controlled and the number of equipped stations is relatively low. We wish to estimate if plant biomonitoring could be an alternative to the regular physico-chemical monitoring methods of this pollutant. The effects of a benzene exposure on plants are still widely unknown. This pollutant enters into the plant mainly by stomata, but also by epidermic distribution before being metabolized (Ugrekheldidze and al. 1997). This whole work tracks the purpose to improve the knowledge of benzene metabolism, to look for and to identify specific biomarkers of the benzene in the leaf of the cabbage *Brassica oleracea*. Short times exposures of plants (1h to 24h) to different doses of benzene (from 150 to 3000 ppb) were conducted. The effects of the benzene were studied by following two approaches. The first one estimated the pollutant genotoxicity and the oxidative stress that benzene generates in the plant. The second approach, an ecotoxicogenomic study, improve the knowledge of the metabolic pathways followed by this pollutant after his enter into the leaf as well as to define a panel of genes for which the expression levels are modulated during an exposure of *B. oleracea* to this COV. The results of this study show that benzene generates a low genotoxic effect and has globally a little impact on the enzymatic anti-oxidative system, although the catalase activity is reduced upon a benzene exposure in a seemingly dose-dependent way. A way toward biomonitoring of benzene seems now opened through the use of gene expression level modulations of a set of defined genes that could represent valuable molecular markers

#### MO005

##### Evaluation of sertraline accumulation and effects in an estuarine decapod using biomarker-based bioassays

A.P. Rodrigues, CIIMAR / METOX Coastal and Marine Environmental Toxicology; L. Santos, Faculty of Engineering - University of Porto / Chemical Engineering; M.J. Ramalhosa, C. Delerue-Matos, REQUIMTE; S.R. Mesquita, Center of Marine and Environmental Research CIIMAR / METOX Coastal and Marine Environmental Toxicology; L. Guimaraes, CIIMAR University of Porto / METOX Coastal and Marine Environmental Toxicology  
The presence of pharmaceuticals in waste and surface waters is posing challenges to

hazard identification and risk assessment. Recent evidence suggests that standard ecotoxicological assays may provide insufficient assessment of such microcontaminants and, hence, water quality. Previous remarks also suggest they should be better addressed by using sensitive biomarkers and adverse outcomes related to their mode of action (MOA). A good example, is that of selective serotonin reuptake inhibitors (SSRI), a group of widely consumed antidepressants, which may elicit different effects in aquatic species at low and high concentrations. For SSRI, disruption of fish behaviour, stress effects and metabolic pathways seem to be more sensitive endpoints than conventional testing based on standard species and growth and reproduction. Organisms of different backgrounds (e.g., genetic make-up, previous exposure history) may also exhibit differential sensitivity to contaminants, although this is seldom addressed. This study investigated accumulation and sub-lethal effects of SSRI sertraline in *Carcinus maenas* from two estuaries with differing contamination histories. A sub-chronic exposure to environmental and high sertraline levels was performed. MOA-related biomarkers were used to assess neurotransmission, energy metabolism, biotransformation and oxidative stress pathways. Besides non-monotonic responses, differing effects were elicited in test crabs, with differences in sensitive of four orders of magnitude between the two estuaries. These included decreased acetylcholinesterase activity, indicative of ventilatory and locomotory dysfunction, inhibition of antioxidant enzymes and increased oxidative damage at  $\geq 0.05 \mu\text{g.L}^{-1}$ . Crabs from a moderately polluted estuary also showed potentially life-threatening effects at concentrations about three orders of magnitude lower than those found for reproductive output in the most sensitive freshwater species tested up-to-date. Results point an influence of previous exposure history on responses to sertraline. They support the need to assess toxicity of pharmaceuticals using Adverse Outcome Pathways and local potentially affected species. Funded by Project ECORISK (NORTE-07-0124FEDER-000055) within the SR&TD Integrated Programme MARVALOR, through Programme ON.2 – O Novo Norte and the ERDF; and by Portuguese Foundation for Science and Technology (Pest- C/MAR/LA0015/2013).

#### MO006

##### **Effect of temperature and cypermethrin on the sentinel species *Mytilus galloprovincialis* measured through a suite of biomarkers in gills**

D. Ortiz, Universitat de Valencia / Dpt Biología Funcional y Antropología Física; I. Varo, Spanish Research Council (CSIC) / Biology culture and pathology of marine species; M. Chiaravalle, Universitat de Valencia; M. Sendra, Universitat de Valencia / Dpt Biología Funcional y Antropología Física; A. Torreblanca, University of Valencia / Department of Animal Biology

Currently one of the biggest problems facing the salmon industry worldwide is high proliferation and spread of sea lice, copepod ectoparasites that reaches high population densities in intensive farms. This problem generates great economic losses to the industry by reducing the health of the fish and indirectly by high treatment costs. In Chile the main insecticides used to lower the parasite loads through direct baths with skirts at sea are pyrethroids (cypermethrin and deltamethrin). These insecticides are applied at high concentrations. Periodic treatments have generated parasite resistance causing treatments to become increasingly ineffective. This has resulted, in turn, in increased volumes of pyrethroids directly discharged to the marine environment. Few studies on environmental toxicological effects on non-target marine species have been performed. This laboratory study evaluated the sub-acute exposure to realistic cypermethrin concentrations (using acetone as vehicle) in the sentinel mussel *Mytilus galloprovincialis* at different temperatures (17–22–27 °C) and two exposure times, using a factorial design. Two general biomarkers of oxidative stress Catalase (CAT) and Glutathione S-transferase (GST) and two specific biomarkers Acetylcholinesterase (AChE) and Carboxylesterase (CbE) were determined in mussel gills. A synergistic effect between cypermethrin and its vehicle (acetone) at 96 hours was found in cypermethrin treatments with an increase activity in CAT and GST, becoming this effect significant at different temperature for each biomarker. The effect of cypermethrin as active ingredient was detected in mussels acclimated to 22 °C as an increase of CbE activity in cypermethrin treatments. It was found a strong effect of acetone (vehicle), inhibiting AChE activity and CbE activity. Temperature acclimation by itself was also found to have a significant effect on enzymatic activities (all of them measured at 20 °C), mainly by inhibiting the CAT activity, increasing AChE activity and producing a bell effect on GST activity. D. Ortiz is recipient of a fellowship from PhD (Becas Chile) for Advanced Human Capital formation pertaining the Ministry of Education of Chile (CONICYT) and funded by the Government of Chile.

#### MO007

##### **Blood cholinesterase activity as biomarker for the diagnosis of organophosphate exposure in birds in chlorpyrifos treated pome fruit orchards in the UK**

M. Foudoulakis, Dow Agrosciences / RSRA ERS; S. Norman, RidgewayEco; F. Sotti, B. Giessing, Tier3 Solutions GmbH; N. Poletika, Dow Agrosciences / RSGAACES; M. Smith, Huntingdon Life Sciences

The activity of cholinesterases, inclusive of both acetyl-cholinesterase and butyryl-cholinesterase (BuChE), has been commonly used as a biomarker for organophosphate (OP) exposure and risk in birds. Analysis of blood plasma cholinesterase (ChE) activity in field-caught birds allows OP exposure to be assessed non-destructively, allowing large numbers of individuals to be sampled,

repeatedly, without impacting the local population. Pome fruit orchards in UK, treated twice each year with the OP insecticide chlorpyrifos (CHP), were selected in 2014 as sites to provide information on the status of bird communities, and to assess blood ChE activity in the same bird communities, providing a diagnostic evaluation of CHP exposure. Field searches showed the presence of different bird species, in all age stages, present before and after CHP application, with blue tit, great tit, blackbird, robin and chaffinch being the most common. Blood samples were taken from approximately 300 individuals (adults and chicks) from 10 species during this study and plasma ChE activity of all species was determined using three ChE inhibitors (BW284C51, iso-OMPA and eserine). For all species studied, the main blood ChE form present was BuChE, and the range of BuChE activity that may be considered as basal levels for non-exposed individuals was determined. The results indicated that for all species BuChE activity was slightly decreased immediately after CHP application; the most prominent decrease was observed in blackbirds. For most cases, the BuChE activity completely recovered after a short period (approximately 10 days). In some species, e.g., blue and great tits, the plasma BuChE activity was higher in adults than in young birds. Moreover, detection of low level exposure, resulting from CHP application, by using plasma BuChE may be a better indicator of exposure than brain ChE because the former is usually inhibited more rapidly and to a larger degree. The work undertaken in 2014 gave a good insight into potential exposure of birds utilizing the pome fruit orchards and showed a good correlation between the application of CHP and BuChE activity.

#### MO008

##### **Toxicity Evaluation Study on Aquatic Organisms of Organic Farming Materials from Plant Extracts for Pest Control in Korea**

K. Park, NAAS, RDA / Chemical Safety Division; J. Oh, M. Paik, NAAS RDA; S. Hong, National Academy of Agricultural Science; N. Cho, NAAS RDA; S. Han, RDA; B. Kim, National Academy of Agricultural Science

In South Korea, organic farming materials are evaluated separately for plant growth and pest control. This study was performed to evaluate the risks of the plant extracts used for pest control, by evaluating the toxicity to carp (*Cyprinus Carpio*) and muddy loach (*Misgurnus anguillicaudatus*) and calculating the estimated concentration in the exposed environment. The fish acute toxicity of plant extracts on carp and muddy loach were low in grade III (48h-LC50 > 2.0 mg/L). The PEC (Predicted Environmental Concentration) using the plant extracts in paddy field of sophora extracts were 0.2–4.32 mg/L and neem extracts were 0.14–12 mg/L. The PEC of derris extracts in river were 0.00036–0.0063 mg/L. The TER (Toxicity Exposure Ratio) using the toxicity values of muddy loach in paddy field of sophora extracts were 3.9–65.2 and neem extracts were 3.0–252.8. The TER using the toxicity values of carp in river of derris extracts were 7476.2–87222.2. As a results of risk assessment, the toxicity of three plant extracts were low for fish. In conclusion, when a company has to submit the organic farming material's toxicity data for governmental registration and certification, among the plant extracts, sophora, neem and derris extracts are desirable to skip the fish acute toxicity data.

## **Behavior Revised: Examining Behavioral Effects of Contaminants and Other Stressors in Aquatic Animals (P)**

#### MO009

##### **Deltamethrin and imidacloprid increase mortality, locomotory impairment and feeding inhibition in damselfly nymphs**

W. Kunce, Animal Ecology; A. Cecelja, University of Leuven; F. Johansson, Uppsala University

We investigated the effects of a 14 h exposure of the insecticides: deltamethrin and imidacloprid as well as mixtures of the two pesticides on the behavior of damselfly nymphs (*Ischnura elegans*). Three nominal concentration levels of deltamethrin were tested: 2 ppb, 0.2 ppb and 0.02 ppb and one concentration of imidacloprid at 20 ppb alone as well as combined with the three deltamethrin concentrations. . Of the 14 exposure hours, the initial 10 were in darkness in accordance with the nymphs' pre-established 14:10 light-dark cycle. The nymphs (n = 14–20) were each observed for 10 minutes in the presence of prey (*Artemia*) 1 hour after the exposure and again 72 hours later. The highest level of deltamethrin, alone and combined with imidacloprid resulted in 100% mortality by the end of the exposure period compared to 0% mortality in the control group. The lower deltamethrin concentrations and imidacloprid single exposures resulted in < 10% mortality whereas the combinations of the two insecticides resulted in a synergistic impact of 30–45% mortality. Imidacloprid alone had no effect on nymph activity (head orientations, steps and swims) or prey capture behavior. The two lower concentrations of deltamethrin saw a 50–62% reduction in activity immediately following exposure suggesting locomotory impairment. The addition of imidacloprid did not significantly alter activity from the single deltamethrin exposures. An alarming 82–87% drop in the amount of prey captured was observed after the 0.2 ppbdeltamethrin exposure, regardless of the addition of imidacloprid. However, while feeding behavior was not affected by 0.02 ppb deltamethrin alone the number of prey captured did drop significantly (~70%) after exposure to this concentration of deltamethrin when combined with imidacloprid, indicating that imidacloprid may in fact contribute to feeding impairment. The negative effects on locomotory and feeding were not observed at the reassessment 72 hours later

indicating recovery. These results showing increased mortality, locomotory impairment and inhibited feeding emphasize the strong toxicity of low, environmentally relevant concentrations of deltamethrin to non-target aquatic organisms and the synergistic effects of combination with imidacloprid on both lethal and non-lethal end-points.

#### MO010

##### **Anti-anxiety drugs and fish behaviour: establishing the link between internal concentrations of oxazepam and behavioural effects**

**B. Huerta Buitrago**, Catalan Institute for Water Research (ICRA) / Department of Water Quality; S. Rodriguez-Mozaz, Institute for Water Research (ICRA) / Water Quality; L. Margiotta-Casaluci, Brunel University / Institute for the Environment; D. Barcelo, IQAB-CSIC / Institute for Environmental Assessment and Water Research; J.P. Sumpter, Brunel University / Institute for the Environment  
Benzodiazepines are pharmaceuticals specifically designed to alter behaviour in humans by modulating the GABA<sub>A</sub> receptor and reducing the communication between neurons. This in turn leads to a calming effect in patients. Benzodiazepines have recently been detected in the aquatic environment and several studies have shown that the GABA<sub>A</sub> receptor is evolutionary conserved in aquatic organisms, including fish, suggesting that these compounds may elicit pharmacological activity in the environment. Among the different benzodiazepines, oxazepam has recently received considerable attention since some studies suggested that this compound may alter fish behaviour at environmentally relevant concentrations. Here we present the results of a study designed to establish the quantitative link between oxazepam concentrations in different tissues (plasma, brain, liver) and its behavioural effects in the teleost fathead minnow (*Pimephales promelas*). This study was designed on the basis of the read-across hypothesis and was conducted by exposing fish to 1, 5, and 25 µg/L of oxazepam for 28 days using a flow-through system. This range of oxazepam water concentrations was chosen to produce plasma concentrations below, equal and above the ones known to induce therapeutic effects in humans. Oxazepam was quantified by LC-MS/MS in plasma, brain and liver of individual fish. Behavioural endpoints were quantified by performing two different tests - Novel Tank Diving Test and Shelter-Seeking test - after 14 and 28 days of exposure. Fish behaviour was analyzed blindly using automated video-tracking software. The full set of results will be presented and discussed together with the implications for the Environmental Risk Assessment of oxazepam.

#### MO011

##### **Effects of cyclooxygenase inhibitor ibuprofen on prostaglandin synthesis and reproductive behavior in zebrafish**

**T. Firkus, D. Martinovic**, University of St. Thomas  
Prostaglandins are a class of hormones important for the regulation of steroidogenesis and ovulation in vertebrates. In fish they are also used as pheromones; they are released by ovulating females and initiate and synchronize male reproductive behaviors. Pharmaceuticals such as nonsteroidal anti-inflammatory pharmaceuticals (e.g., ibuprofen; IB) are designed to inhibit mammalian cyclooxygenase (COX) enzymes which catalyze prostaglandin synthesis. The aim of the present study was to examine the effects of 14 day exposure to IB (50 µg/L) on ovarian COX activity and prostaglandin F<sub>2</sub>-alpha (PGF<sub>2a</sub>) concentrations, as well as reproductive behaviours associated with prostaglandins. Effects of IB on prostaglandin synthesis pathway were also evaluated; we measured phospholipase, COX 1, COX 2, and prostaglandin synthase mRNA abundance using real time polymerase chain reaction. A slight decrease (17%) in mean ovarian COX activity of IB-exposed females was observed but this finding was not statistically significant. A similar pattern was found for the ovarian PGF<sub>2a</sub>; a decrease (34%) of ovarian PGF<sub>2a</sub> was observed in the IB-exposed females, but the difference was not statistically significant. IB-exposed males performed "Tail-Nose", "Encircle", and "Quiver" behaviors with significantly lower frequency than control males. Attraction behaviour tests indicated that release water samples collected from IB-exposed females were comparably attractive (to unexposed males) as those collected from the control females. Nevertheless, unexposed males exhibited significantly higher activity levels when encountering release water from the control females (10.78 ± 2.74, n=16) vs. IB-exposed females (8.94 ± 2.62, n=24). Our data suggests that short-term exposure to ibuprofen (at high concentrations similar to those found in heavily polluted wastewater effluents) likely impacts quality/quantity of chemical signals released by females, and has a potential to alter male-female interactions in reproductively mature zebrafish. It remains to be determined whether observed behavioural alterations may reduce male's ability to locate spawning females and secure reproductive opportunities. Behavioural endpoints seemed to be more sensitive than the physiological endpoints (COX activity, ovarian PGF<sub>2a</sub>) suggesting a greater need for inclusion of behavioural endpoints in the future assessments of COX inhibitors.

#### MO012

##### **Species-specific exposure and vulnerability to pharmaceuticals generate asymmetric behavioural effects both within and between trophic levels.**

**T. Brodin**, Umea University / Department of Ecology and Environmental Science; M. Jonsson, Department of Ecology and Environmental Science; J. Fick, Umea University / Department of Chemistry; M. Heynen, Umea University / Department

of Ecology and Environmental Science; J. Klaminder, Ecology and Environmental Science

Pharmaceutical residues are found in many aquatic ecosystems all over the world. One group of pharmaceuticals of particular interest for potential behavioural effects is anxiolytic drugs since they are designed to alter human behaviour. There is a growing awareness among ecologists that behavioural variation and alterations are important for individual performance, ecosystem function, and species evolution [4]. In ecotoxicology it has been recognised that such behavioural alterations may be caused by contaminants found in natural systems. Recent studies have shown anxiolytic drugs to be present in environmental concentrations high enough to effect behaviour of fish. Very little is, however, known about how/if these compounds affect the behaviour of other aquatic organisms. Information of how/if other key species are affected by exposure is crucial to be able to predict to what extent major ecological effects can be expected. Higher risk for severe ecological impact is predicted if the degree of which species specific behavioural effects occurs. That is, if pharmaceutical contamination induce behavioural effects that are asymmetric between species. Such asymmetric effects can lead to shifts in species densities and compositions through altered competition and predator-prey interactions. The ecological ramifications of such pharmaceutically induced asymmetric behavioural changes are still unclear, as to date no studies have investigated the issue. We measured bioconcentration and behavioural effects in 1-year-old perch and damselfly larvae following an exposure (7 days) to water containing 2.1 µg l<sup>-1</sup> of an anxiolytic pharmaceutical (oxazepam). In accordance with earlier studies, oxazepam exposure affected perch behaviour. Perch became significantly more active (N = 30, F = 8.0, N = 30, p = 0.007) after oxazepam exposure, while perch activity in the control did not change between before and after as shown by a significant interaction between treatment and time (N = 30, F = 5.4, N = 30, p = 0.023). For damselflies, we found no significant effect of oxazepam exposure on larval activity (p > 0.80), indicating that invertebrate behaviour, in contrast to perch behaviour, is unaffected by oxazepam exposure at this concentration. These and other results are discussed in both an ecological and ecotoxicological context.

#### MO013

##### **Visual and chemical cues - does EE2 exposure affect male mate choice of a freshwater fish?**

**M. Saaristo**, R. Jacques-Hamilton, Monash University / School of Biological Sciences; M. Allinson, The University of Melbourne / School of Chemistry; M.G. Bertram, Monash University / Biological Sciences; C.P. Johnstone, B.B. Wong, Monash University / School of Biological Sciences

Aquatic habitats are increasingly being exposed to chemicals that, even at low levels, can disturb the endocrinology of organisms. One class of environmental contaminants posing a severe threat to freshwater ecosystems globally is that of endocrine disrupting chemicals (EDCs). Typically, research on EDCs has focused on physiological or morphological changes that can arise from exposure. Few studies have explored the effect of EDCs on behaviour. Among those that have, we know that behaviour can be affected at concentrations far lower than typically used to explore physiological or morphological trait changes. Thus, changes in behaviour can provide a more sensitive early-warning signal for the presence of EDCs in the environment. The aim of this study was to investigate the impacts of short-term (24-day) exposure to an environmentally relevant concentration (5ng/L) of 17α-ethinyl estradiol (EE2) on male mate choice in the guppy. To do this we asked two questions: 1) Do males discriminate between exposed and control females when only presented with visual cues? 2) Do males discriminate between exposed and control females when presented only with chemical cues? To investigate the impact of EE2 on visual and chemical communication of guppies two behavioural experiments were employed: (1) a male was presented with a choice between the visual cues of an exposed and a control (i.e. non-exposed) female, and (2) a male was presented with a choice between the odour cues of an exposed and a control female. Both female and male behaviour were video-recorded. We found that EE2-exposed males spent significantly more time associating with exposed females when they could only use visual cues. On the contrary, when they were given only chemical cues to choose from, EE2-exposed males visited control female chemical cue more often than EE2-female cue. Interestingly, control females spent significantly more time associating with control males and repeated that behaviour more often than EE2-exposed females. Our study shows that short-term exposure to environmentally relevant concentration of EE2 alters male mate choice and female behaviour in the guppy. This is the first study to show that EE2-exposure does not impair male ability to sense or respond to chemical cues. Not only does our study uncover a previously unknown behavioural impact of EE2-exposure on guppy female behaviour, but highlights the need to study multiple mate choice contemporaneously.

#### MO014

##### **Behavioral alterations following exposure to copper, phenanthrene, and copper-phenanthrene mixtures: linking behavior to acute toxic mechanisms in *Hyalella azteca*.**

**P.T. Gauthier**, Natural Resources Management; E.E. Prepas, Lakehead University / Department of Natural Resources Management; G.G. Pyle, University of Lethbridge / Biological Sciences  
Phenanthrene (PHE) and copper are two contaminants commonly co-occurring in

marine and freshwater environments. Exposure to copper and PHE has been shown to alter the behaviour of fish and crustaceans. *Hyalella azteca* use pleopod appendages to ventilate the gills and promote respiration. Impaired ventilatory behaviour would reduce oxygen consumption, which would in turn effect a variety of additional behaviors (e.g., activity, swimming performance, and phototaxis). Moreover, reduced oxygen consumption presents a potentially lethal physiological effect. Virtually nothing is understood regarding the effects of copper and PHE on the behavior of *H. azteca* and the mechanisms responsible for behavioral alteration. Nonetheless, copper and PAHs are neurotoxic produce reactive oxygenated species (ROS). Accordingly, we explored the effects of copper, PHE, and copper-PHE mixtures on oxygen consumption, ROS production, acetylcholinesterase (AChE) activity, and a suite of behavioral endpoints (i.e., activity, velocity, distance travelled, phototaxis, and pleopod beating). Our principle objective was to link behavioral alterations with oxygen consumption rates, ROS imbalance, and neurotoxicity in adult *H. azteca*. Adult amphipods (>6 weeks old) were used for all toxicity tests. Amphipods were exposed to 20 µg L<sup>-1</sup> copper, 200 µg L<sup>-1</sup> PHE, and a mixture of 20 µg L<sup>-1</sup> copper and 200 µg L<sup>-1</sup> PHE for 24 hrs. Immediately following the 24-hr exposure period, activity, distance travelled, velocity, phototaxis, and pleopod beats per minutes were measured. The same animals were then used to measure ROS levels using the dichlorofluorescein biomarker coupled with fluorescence microscopy. Oxygen consumption was measured via conventional closed respirometry, and AChE activity was measured following Ellman's method. Activity, distance travelled, velocity, phototaxis, and pleopod beating were all significantly and greatly reduced (e.g., 50% to 100% below control) following exposure to PHE. However, copper had no effect on amphipod behavior. Exposure to PHE did not produce ROS, whereas copper elicited a 40% increase above control, indicating that ROS imbalance is not responsible for behavioral alterations in *H. azteca* following acute exposures. AChE activity assays are underway, and may provide a mechanistic explanation for behavioral impairment following exposure to PHE.

#### MO015

##### **Alcohol, coffee and cigarettes: evaluation of candidate positive control chemicals for behavioural assessment in zebrafish early life stages**

C. Di Paolo, RWTH Aachen University / Ecosystem Analysis ESA; J. Legradi, Institute for Environmental Studies; K. Graf, RWTH Aachen University / Department of Ecosystem Analysis ESA; R. Ottermanns, RWTH University; I. Werner, Swiss Centre for Applied Ecotoxicology / Department of Anatomy Physiology and Cell Biology; M. Fenske, Fraunhofer Gesellschaft IME / Ecotoxicology; J. Legler, VU University / Institute for Environmental Studies; H. Hollert, RWTH Aachen University / Institute for Environmental Research; T. Seiler, RWTH Aachen University / Ecosystem Analysis

The assessment of behavioural endpoints in zebrafish early life stages (ELS) can indicate organism-level responses to the most varied environmental contaminants. However, the procedures applied to evaluate behavioural changes are not clearly defined and vary a lot between laboratories and studies. This makes the interpretation and validation of experimental results very challenging. Behavioural assessment in zebrafish ELS would clearly benefit from the standardization of protocols. Therefore this study aimed to: investigate candidate positive control chemicals for behavioral testing with zebrafish ELS; and evaluate whether zebrafish ELS exposed to the same experimental procedures in two different laboratories would display comparable behavioural responses. The same set of experiments was performed at the Institute for Environmental Studies - VU University; and at the Institute for Environmental Research - RWTH Aachen University. At VU, the automated video tracking system from ViewPoint was used; while at RWTH a custom-made system combined with the EthoVision software (Noldus) was applied. Zebrafish ELS were exposed to several concentrations of ethanol, caffeine and nicotine, and behaviour was studied at ≤ 5 days post fertilization (dpf). Long-term exposures between 0-5 dpf as well as short term exposures at 5 dpf (i.e. for 10 min, 40 min and 1.5 h) were performed. Medium and solvent control conditions were included. Exposed zebrafish were submitted to light-dark short transition challenge, and video tracking of locomotion was performed for two cycles of transitions. Locomotion data was analysed for parameters as total distance moved, burst activity, and ratio dark:light activity. Stimulated or suppressed behaviour were evaluated concerning the concentrations of compounds, temporal patterns, and experimental set up. The intra and interlaboratory reproducibility between replicate experiments was evaluated. In our study, comparable behavioural patterns between laboratories were observed for the same compounds and exposure periods. However, some sensitivity differences were observed regarding compound concentrations. It is considered that positive controls might be useful to counteract those differences, by applying positive control conditions in adequate exposure scenarios. In general our results clearly indicate the need and usefulness of interlaboratory comparisons, which can help to improve behavioural assessment in zebrafish ELS.

#### MO016

##### **Behavioural Effects of Coal Mine Wastewater in Australian Species**

C. Lancot, Central Queensland University / School of Medical and Applied Sciences; S.D. Melvin, Smart Water Research Centre / Centre for Environmental Management; L. Fabbro, Central Queensland University / School of Medical and Applied Sciences; F.D. Leusch, Griffith University - Smart Water Research Centre

/ School of Environment and Smart Water Research Centre; S. Wilson, CQ University / School of Medical Applied Sciences

Coal mining represents a major economic activity, particularly so in Australia, but concerns about potential environmental effects necessitate effective monitoring strategies. Substantial volumes of mine wastewater may be discharged into the environment, through both planned and accidental releases. These discharges can be highly saline and may often contain high levels of dissolved solids, suspended solids, heavy metals, hydrocarbons and other compounds. Traditional toxicological testing has generally involved assessment of acute or chronic toxicity, and while such tests provide useful information, they are poorly suited to ongoing monitoring or rapid assessment following accidental discharge events. We therefore investigated behavioural responses of native Australian fish and cladocerans as a tool for evaluating potential sublethal effects of coal mine wastewater releases on freshwater ecosystems. Organisms were exposed to wastewater from two dams (0-100% CMW1 and CMW2) located at an open cut coal mine in Central Queensland, Australia. Behaviour was monitored using both EthoVision XT 9.0 video-tracking software (Noldus Information Technology, Netherlands) and the Multispecies Freshwater Biomonitor® (MFB, LimCo International GmbH). In experiments using the MFB, native fish (*Hypseleotris compressa*) exposed to coal mine wastewater showed a rapid reduction in time spent swimming and a slight increase in ventilation rates compared to controls. These effects were observed within 24 hours of exposure and persisted over the two-week exposure. Alternately, in experiments using the EthoVision software, exposed *H. compressa* showed an increase in activity and spent more time near the arena border compared to controls after a two-week exposure. In experiments with cladocerans, wastewater from one site (100% CMW2) resulted in acute toxicity (100% mortality after 48 hours) and rapid changes in swimming patterns were observed in exposed animals. Water quality and chemistry analysis showed temporal variations in wastewater collected for the different experiments, which likely explains inconsistencies in responses. The results indicate the potential for using behavioral endpoints in native species as tools for monitoring wastewater discharges. However, future experiments are needed to investigate the sensitivity of these tools for realistic environmental concentrations, and explore the practicality of these techniques for *in situ* monitoring.

#### MO017

##### **Can Psychiatric Pharmaceuticals Alter the Correlation Between Behaviours in Fish?**

A. Lagesson, Department of Ecology and Environmental Science; J. Klaminder, Ecology and Environmental Science; J. Fick, Umea University / Department of Chemistry; M. Jonsson, Department of Ecology and Environmental Science; T. Brodin, Umea University / Department of Ecology and Environmental Science

Pharmaceuticals in aquatic environments are today recognized as a global problem. Psychiatric drugs, such as anxiolytics and antidepressants, are a large group of pharmaceuticals that enter aquatic systems and remain biochemically active. A number of studies have demonstrated that psychiatric drugs can alter the behaviour of aquatic organisms, with possible consequences for aquatic ecosystems. Individuals of many species display behavioural differences, i.e. behavioural traits, that are consistent within individuals over time and between contexts. Certain sets of behaviours show relationships (behavioural syndromes) that are consistent across ecological situations, suggesting limited behavioural plasticity. One way that psychiatric drugs might affect ecosystems is by modifying behaviour syndromes, with the potential to cause cascading effects on ecosystem functions. Knowledge regarding this is, however, so far limited. In this study, we hypothesized that psychiatric drugs can alter correlations between behavioural traits of wild fish. Our hypothesis was tested by synthesizing data from laboratory behaviour assays. The substantial data (n > 200), collected from wild caught individuals of European perch (*Perca fluviatilis*), revealed effects on two ecologically important behaviours: activity and sociality. We examined how these two traits were correlated before and after exposure to two different drugs: an anxiolytic (Oxazepam) and an antidepressant (Mirtazapin). We found that the correlation between the two studied behavioural traits were affected by Oxazepam and to a lesser extent by Mirtazapin. The findings imply that psychiatric drugs in surface waters have the capacity to not only modify single behavioural traits, but also the way in which different types of behaviours are related to each other.

#### MO018

##### **Antihistamines and aquatic insects: Bioconcentration and impacts on behavior in damselfly larvae (Zygoptera)**

M. Jonsson, Department of Ecology and Environmental Science; J. Fick, Umea University / Department of Chemistry; J. Klaminder, Ecology and Environmental Science; F. Finn; T. Brodin, Umea University / Department of Ecology and Environmental Science

Aquatic insects use histamines as neurotransmitters and as wastewater are not cleansed from these chemicals it is reasonable to argue that they will be affected. In a study damselfly larvae was exposed to low concentrations of two commonly used antihistamines (Hydroxyzine and Fexofenadine, 360 ± 42 and 2200 ± 43 ng l<sup>-1</sup>, respectively), and damselfly larvae behavior was recorded before and after exposure. After Hydroxyzine exposure, the damselfly larvae became less active, and they showed reduced fleeing response (i.e. increased boldness) after being exposed to Fexofenadine, the latter also being significantly different from the

non-exposed (control) individuals. We also found high levels of bioconcentration in the damselflies; Hydroxyzine showed an average bioconcentration factor (BCF) of 2000. Our results indicate that low concentrations of antihistamines can have sub-lethal effects on aquatic insects manifested as behavioral changes, and that bioconcentration of these substances can be high. We, therefore, highlight the need to further investigate the impact these aquatic contaminants can have on ecologically relevant behaviors.

#### MO019

##### **Growth, Condition and Swimming Performance of juvenile Empire Gudgeons (*Hypseleotris compressa*) Following Short-term Exposure to Wastewater Treated in a Constructed Wetland**

S.D. Melvin, Smart Water Research Centre / Centre for Environmental Management; J.P. van de Merwe, Griffith University / Smart Water Research Centre; F.D. Leusch, Griffith University - Smart Water Research Centre / School of Environment and Smart Water Research Centre

There is growing interest into the use of Constructed Wetlands (CWs) for the treatment of domestic sewage, due to their relatively low operational costs and reported capacity to effectively remove nutrients, microbes and various emerging contaminants from wastewater. Throughout regional Australia, CWs are particularly important for wastewater treatment in rural and remote communities, where intensive treatment options are not practicable. Climatic conditions in Australia generally allow wetland operators to retain water during long dry periods, and to time discharges so that they coincide with peak rainfall events. As such, aquatic animals will optimally be exposed for only short timeframes, and to highly diluted wastewater. Longer duration exposures of aquatic organisms to treated sewage wastewater have frequently observed growth effects and responses indicative of estrogenic activity, but no apparent studies have investigated responses in native Australian species exposed to CW wastewater under relevant exposure conditions. To this end, juvenile Empire Gudgeons (*Hypseleotris compressa*) were exposed to 0, 6.25, 12.5, 25, 50 and 100% dilutions of treated CW wastewater for a period of two weeks, and growth and swimming performance were quantified following exposure. There was little evidence of estrogenicity, which was confirmed through chemical and *in vitro* analysis, but significantly increased weight and condition were observed in fish exposed to 50 and 100% wastewater dilutions. A positive correlation was observed between condition and swimming velocity, indicating the potential for nutrient enrichment resulting from wastewater discharge to indirectly affect the functional performance of fish exposed at early-life stages. However, overall the results suggest that properly operated CWs, ensuring appropriate dilution through intermittent short-term discharges during the wet season, may effectively mitigate the potential for adverse toxicological outcomes in fish living in aquatic receiving environments.

#### MO020

##### **Behavior, growth and biochemical responses of *Gammarus pulex* to prochloraz and fluoxetine exposure in a feeding experiment**

N. De Castro, Departament d'Ecologia; I. Muñoz, University of Barcelona / Ecology; A. Ford, University of Portsmouth / Institute of Marine Sciences

The development of toxicity tests based on single species responses has been widely proposed as a complementary tool to biological and chemical conventional surveys. Nonlethal endpoints are more sensitive than mortality or community structural changes and can be used as early warning indicators of toxic stress. The use of detritivores to detect specific effects of pollutants is currently becoming a well-known method. However, the application of feeding tests as early detection tools of toxic risk in freshwater ecosystems is still scarce. A feeding experiment was carried out to detect indirect (leaf conditioning) and direct effects (water exposure) of two pollutants, the fungicide prochloraz and the antidepressant fluoxetine, in the freshwater amphipod *Gammarus pulex*. Behavioral (feeding rates, movement responses to light after exposure), biochemical (CNP) and growth endpoints were combined to detect the toxic effects of the compounds. Alder leaves were conditioned during 14d under three different treatments: 6 µg/L of prochloraz, equivalent to the LC50 values reported for algae; 100 ng/L of fluoxetine; and the mixture of both compounds. *G. pulex* adult individuals were fed during two weeks with the different treated leaf discs. In the feeding experiment the four conditioning treatments (control, 100 ng/L fluoxetine, 6 µg/L prochloraz and the mixture of both compounds) were combined with two treatments: exposure to 100 ng/L of fluoxetine and control in order to study the direct effects of this pharmaceutical in the behavior. Chlorophyll a, ergosterol and CNP levels of the leaves were analysed. After the experiment, *G. pulex* behavioral responses to dark-light treatment were analysed with DanioVision, using Ethovision XT software. Preliminary results of *G. pulex* behaviour after 14d exposure confirm what recently has been reported: there is an increase in the activity of the amphipod after the exposure to fluoxetine. Moulting rates during the experiment were higher in the fluoxetine treatments. On the other hand, the amphipods exposed to both compounds at the same time showed low activity after the exposure. The information given by all the biomarkers may allow to establish links between the leaf litter conditioning, the feeding behavior, and the locomotive behavior after the exposure. The combination of these different endpoints might provide a useful tool for early detection of toxicity mixtures in freshwater ecosystems.

#### MO021

##### **Behavioural and transcriptomic changes in crustaceans in response to antidepressant exposure**

M.C. Bossus, S. Short, S. Kohler, Y. Guler, University of Portsmouth; A.T. Ford, University of Portsmouth / Biological Sciences

Recent studies have suggested that invertebrates might be highly sensitive to antidepressants, such as the Selective Serotonin Re-uptake Inhibitors (SSRIs), the Serotonin-Norepinephrine Re-uptake Inhibitors (SNRIs) and Serotonin Antagonist and Re-uptake Inhibitors (SARIs). These drugs alter serotonin levels in the synaptic cleft by inhibiting its re-uptake into the presynaptic cell, which result in increased stimulation. Within the invertebrates, many biological functions including reproduction, maturation, metabolism, moulting as well as behaviour can be under control of serotonin. This ongoing study is currently analysing the effects of a variety of antidepressants on phototaxis and predator-avoidance-related behaviour and neurological endocrine disruption in the amphipod *Echinogammarus marinus*. Behavioural and transcriptional changes in this crustacean were studied when exposed to the most prescribed SSRIs (citalopram, sertraline and fluoxetine), SARI (trazodone) and SNRI (duloxetine). The animals were exposed to these five drugs at environmentally relevant concentrations from 0.001 to 1 µg/L during short-term (1 hour and 1 day) and medium-term (8 days) experiments. The movement of the amphipods was tracked using the behavioural analysis DanioVision during 12 min alternating dark/light conditions. Furthermore, the expression of genes with putative neurological functions were quantified in these animals using qPCR. In addition, we have applied high-throughput sequencing technology to exposed animals to reveal the broad transcriptomic responses to these compounds. So far, results have revealed significant changes in amphipods behaviour and their neurophysiology following exposure to low and environmentally relevant concentrations of antidepressants.

#### MO022

##### **Prozac effect on a predator-prey system (mosquito fish-egret): an experimental approach**

S. Villa, C. Ferrario, University of Milano Bicocca; A. Finizio, University Milano - Bicocca; M. Parolini, University of Milan / Biology; N. Saino, University of Milano; M. Vighi, University of Milano / Earth and Environmental Sciences

Traditional ecological risk assessment approaches, based on dose/concentration-response relationships, suffer for a lack of ecological realism. A better understanding of effects on ecosystems needs more sophisticated endpoints, such as secondary effects, behavioral changes, etc. The experimental approach described is aimed to study the effects of an emerging pollutant frequently detected in urban sewage and surface water: fluoxetine (FLX), the active ingredient of Prozac. The effects of FLX on aquatic animals have been investigated in the last few years. However, the responses of an aquatic-terrestrial prey-predator system have never been studied. The work will assess behavioral and indirect ecological effects on such an ecological system. The mosquito fish (*Gambusia holbrooki*) and little egret (*Egretta garzetta*) are selected as biological targets. The population of prey can induce effects on population dynamics of predators, modifying the mean Darwinian fitness and productivity. Changes in the ecology of the prey, induced by changes in ecological conditions or in the interactions with other species, can then have indirect effects on predator. The project will focus on the prey behavioral changes induced by FLX. Mosquito fish will be exposed for 21 days to environmentally relevant concentrations of FLX. Different behavioral endpoints will be assessed (e.g. swimming performance, social behavior, etc.). The second part of the project will evaluate the predatory efficiency of unexposed and FLX-exposed herons. FLX-exposed egrets will be fed with exposed mosquito fishes before the experiment. During the test, egrets can concurrently prey from one tank, fishes exposed on different FLX levels twice a day after 12 hours fasting. Behavioral effects on swimming ability of mosquito fish and on predator-prey interaction will be monitored by video tracking. Data will be analyzed with Poisson hierarchical linear models mixed-effects.

#### MO023

##### **Behavioural responses of freshwater planarians after short-term exposure to the insecticide Chlorantraniliprole**

A.C. Rodrigues, CESAM Biology; C. Barata, CSIC / Environmental Chemistry; A.M. Soares, Universidade de Aveiro / Department of Biology and CESAM; J.L. Pestana, CESAM & University of Aveiro / Department of Biology and CESAM

Planarians share most neurotransmitters and receptors with more complex animals, there are evidences that behavioural responses of planarians to drugs acting on neural transmission are similar to those seen in mammals. However there is a lack of studies dealing with effects of other neurotoxic compounds on planarians. As such, a comprehensive investigation of behavioural responses of planarians to neurotoxic pesticides can be relevant for ecological risk assessment and an important alternative to the use of vertebrates in toxicity testing. Chlorantraniliprole (CAP) is an insecticide that belongs to the newest antranilic diamide class and acts by activation of the ryanodine receptors, causing depletion of intracellular calcium stores disrupting muscle contraction and feeding behavior leading to paralysis and death. Since the sub-lethal effects of CAP on aquatic non-target species are not well characterized the main objective of this study was to assess the behavioral effects of short-term exposure to CAP using the freshwater planarian *Dugesia subtentaculata*. For that purpose, 96 h exposures to different CAP concentrations were performed, in complete darkness. Effects on behavior were assessed by different methods.

Locomotor velocity assay was used to monitor planarian mobility for a period of 3 min per organism. A new feeding inhibition test was developed where, chironomid larvae were added as food and feeding rate (n° or larvae ingested) assessed for 24 h. Finally, planarian mobility was assessed using an automated video recording systems. This system allows an automated high throughput tracking of movements and covered distance of organisms. Our results indicate that *Dugesia subtentaculata* is a suitable organism for laboratory behavioural assays, responding to insecticide stress after short-term exposure. Although *D. subtentaculata* showed higher tolerance to CAP compared to freshwater insects, behavior was significantly affected in exposed organisms. Planarians exposed to CAP showed a decreased locomotor velocity and feeding rate. This work intends to present different methods to assess behavioural effects of contaminants and other stressors on planarian behavior. The advantages and sensitivity of the different behavioral assays will be discussed as well as the ecological relevance of behavioral endpoints in the context of trophic interactions, indirect effects of and ecological risk assessment of neurotoxic pesticides.

## MO024

### Midge (*Chironomus riparius*) and lamprey (*Lampetra fluviatilis*) larval behavior as indicator of sediment toxicity

J. Salmelin, University of Jyväskylä / The Department of Biological and Environmental Science; H. Hamalainen, University of Jyväskylä; A. Karjalainen, ECHA-European Chemicals Agency; M.T. Leppanen, Finnish Environment Institute / Laboratory Centre; H. Kiviranta, National Institute for Health and Welfare / Department of Environmental Health; J.V. Kukkonen, University of Jyväskylä / Biological and Environmental Science; K. Vuori, Finnish Environment Institute / Syke Laboratories

Biological early warning systems, by measuring whether a stress response of an organism is within its normal range, alert rapidly when a toxicant is present in water or sediment. We evaluated if behavioral responses of chironomid and lamprey larvae could be used as indicators of toxicity of dioxins and mercury in sediments. We collected contaminated surface sediments from R. Kymijoki across a pollution gradient (six sites) with known history of industrial pollution, and from an external reference site (R. Urpalanjoki) not affected by industrial effluents. These field sediments were used in the laboratory exposures. First we analysed concentrations of polychlorinated dibenzo-*p*-dioxins, -furans (PCDD/Fs), polychlorinated biphenyls (PCBs) and mercury (Hg) in the sediments. Also body burden of PCDD/Fs and PCBs were analysed from lamprey larvae collected from the study sites when present. We measured larval behavioral responses, locomotion and ventilation, via Multispecies Freshwater Biomonitor, which quantitatively records different behavioral patterns of animals by impedance conversion technique. Chironomid larval behavior was measured after a 10d exposure, and lamprey larvae at 0, 3, 7, 14 and 28d. Also mortality and chironomid growth were used as end points. Longitudinal contamination gradient in Kymijoki sediments ranged from the highest (8 420 ng g<sup>-1</sup> dw) PCDD/F concentrations in the upper section of the river to the lowest concentrations (370 ng g<sup>-1</sup> dw) near the river mouth. PCDD/Fs and Hg concentrations correlated strongly, the highest Hg concentration being in the upper river (1.2 µg g<sup>-1</sup> dw). Body concentrations of PCDD/Fs in lampreys were two orders of magnitude and of PCBs one order of magnitude higher in R. Kymijoki than in the reference river. Congener concentrations correlated strongly between the sediment and larval fat tissue of lampreys both for PCDD/Fs (Spearman  $\rho = 0.90$ ,  $p < 0.001$ ) and for PCBs (Spearman  $\rho = 0.86$ ,  $p < 0.001$ ). Chironomid growth was reduced in some of the contaminated sediments, but there were no differences in mortality among the sediment exposures. We did not detect any consistent differences in behavioral responses of chironomids or lampreys between contaminated and reference sediments indicating that these two species might not be appropriate sentinels of sediment contamination by PCDD/Fs, PCBs and Hg.

## MO025

### Impact of substrate colour on macrofouling

M.A. Bighiu, Applied Environmental Science; A. Eriksson-Wiklund, Stockholm University / Applied Environmental Science; B. Eklund, Stockholm University / Department of Environmental Science and Analytical Chemistry ACES

Biofouling of ships and leisure boats gives rise to many economic and environmental problems. Thus, there is a need for preventive measures, most commonly in the form of antifouling paints. Nevertheless, there are several well-known physical factors that influence the biofouling process, such as temperature, water currents, substrate colour and texture, etc. The aim of our study was to investigate the role of substrate colour on the settlement of different macrofouling species. While most other studies used painted panels for this kind of testing, we were interested in separating the effect of substrate colour from the effect of the active substances in the paints and therefore we used non-toxic plastic panels coming from food packaging. The most common colours of boat hulls were used for this exposure, i.e. black, white, blue and red (N=35 for each colour) as well as transparent panels (N=22) that served as 'substrate controls'. The panels were attached on PVC bars and immersed in water, in vertical position, at a depth of 1.5 m for 21 days, after which the macrofouling species were identified and the dry biomass was determined. The results show that different species have different preferences for substrate colours. Thus, barnacles (*Balanus* sp.) settled predominantly on darker colours while mussels (*Cerastoderma* sp.) were most abundant on blue and transparent panels. These results show that the colour of the

substrate is an important factor in the biofouling process and it should be taken into consideration in antifouling paint formulations. Therefore, choosing lighter colours for coating boat hulls can reduce macrofouling to a certain extent.

## MO026

### Effects of silver ions and nanoparticles on zebrafish (*Danio rerio*) larvae locomotion

G. Asmonaite, K. Bresolin de Souza, University of Gothenburg / Department of Biological and Environmental Sciences; L. Forlin, University of Gothenburg; J. Sturve, Goteborg University / Zoophysiology Dept

The assessment of fish behaviour is gaining more recognition in ecotoxicological research due to its high sensitivity compared to conventional LC<sub>50</sub> screenings and its compatibility with the 3Rs principle. The behavioural endpoints have a great potential to capture complex biochemical and physiological consequences exerted by toxicant exposure on the organism level and can be used as a screening instrument to assess the health status of exposed animals. As it has been previously reported, silver can potentially affect the neurodevelopment and cause behavioral retardations in early life stages of zebrafish (ZF). In this study, we exposed ZF embryos to a wide range silver (Ag<sup>+</sup> and AgNPs) concentrations and evaluated developmental toxicity according to standardized FET (Fish Embryo Toxicity) test criteria. The locomotion activity of ZF larvae was quantified at 120 hpf via View Point® Video tracking system using a customized behavioural assay. A set of repeated episodes of light/dark stimulation was used to artificially stress and evoke visual motor responses, which were used as endpoints for sublethal toxicity. Complementary, to undermine the mechanistic nature of silver toxicity, gene expression of biomarkers for oxidative stress (*NRF2*) and metal toxicity (*MT*) were analyzed. The present study demonstrated that both silver species caused adverse effects on development and inhibited hatchability. The ionic silver exposure compromised higher toxicity than AgNPs both on the behavior and the gene expression. Our findings suggest that high Ag<sup>+</sup> exposure concentrations have a negative (suppressing) effect on locomotion, whereas low and environmentally relevant concentrations have a potential to exhibit hyperactivity on the developing ZF larvae.

## MO027

### Effect of oil sands process-affected water on *Daphnia magna* feeding and reproduction

E. Lari, Biological Sciences; E. Mohaddes, G.G. Pyle, University of Lethbridge / Biological Sciences

The amount of stored oil sands process-affected water (OSPW) in tailing ponds, produced by the surface-mining oil sands industry in northeastern Alberta, poses an environmental risk due to its potential toxicity to aquatic organisms if released into natural receiving waters. In this work, the toxicity of OSPW on *Daphnia magna* was studied using ecologically relevant endpoints, including mortality, growth, reproductive output, and feeding behaviour. Two batches of OSPW from different sources were studied in order to capture some of the variability associated with OSPW characteristics. In short-term experiments we examined the feeding behaviour of neonates (less than 24 h old) and one week old *D. magna* to each of the OSPWs. *Daphnia* were exposed to a dilution series (20, 10, 5, 2.5, and, 1.125%) of each OSPW and were fed similar quantities of *Pseudokirchneriella subcapitata* for 24 h. *Daphnia* food consumption was determined by evaluating how much algae remained after a fixed period of grazing. In long-term experiments the effect of OSPW on feeding behaviour, growth, and reproduction of *D. magna* was studied. In this experiment neonate *D. magna* were exposed to OSPWs (10 and 1%) for 21 days. The number of neonates produced and the mortality of test animals were recorded daily during the exposure. A feeding assay was conducted as described at 7, 14, and 21 d and the growth rate was determined by measuring length and dry weight at the end of the 21 d exposure. Although none of the OSPW exposures resulted in acute lethality, results of both short- and long-term exposures showed that OSPW significantly inhibits the feeding behaviour, suppresses the growth, and reduces the reproductive output of *D. magna*. These results are consistent with the hypothesis that OSPW may affect ecological function through bottom-up trophic cascades

## MO028

### The importance of undisturbed sediment patches in a heterogeneous contamination scenario for habitat selection by snails

C.V. Araujo, Central Department of Research DCI; M. Martinez-Haro, IMAR-CMA (Marine and Environmental Research Centre / Department of Life Sciences; A. Pais-Costa, J. Marques, MARE Marine and Environmental Sciences Centre / Department of Life Sciences IMAR CMA; R. Ribeiro, University of Coimbra

Environmental disturbance can be decisive for habitat selection by organisms as staying in a disturbed environment might suppose some costs. Therefore, the displacement towards less disturbed environments is expected, mainly when health status is threatened by, for instance, contamination. In the present study, the snail *Hydrobia ulvae* was exposed to cadmium spiked sediment with four different concentrations: 0, 15, 100 and 150 mg kg<sup>-1</sup>. Sediment samples were patchily disposed in plates, which were divided in 25 fields, being six fields (subreplicates) used for each sediment concentration; the central area was not filled with sediment and in this field 24 organisms were initially put in. Experiments were performed

with three spatial replicates, and observations were made at 2, 4 and 6 h (corresponding to immediate response), 8, 10 and 12 h (very short term), and 24 h (short term). A clear trend to avoid contaminated sediment patches was observed at immediate and very short time, corroborated by a significant ( $p < 0.05$ ) preference by control patches. After 24 h, organisms exposed to the higher level of contamination seem to have lost the ability to move and, therefore, the avoidance was impaired. Distributed heterogeneously uncontaminated sediment patches can offer the possibility for a rearrangement of local snail population with no necessity to move towards a different ecosystem.

## MO029

### Using a freshwater clam valve rhythm dynamics-based novel valvometry technique to detect waterborne copper

L. Jou, National Ilan University; B. Chen, MingDao University; W. Chen, National Taiwan University / Dept Bioenviron Sys Eng; C. Liao, National Taiwan University / Department of Bioenvironmental Systems Engineering  
The purpose of this study was to use an improved valvometry technique as a detection system to effectively measure waterborne copper (Cu) based on valve activity dynamics in freshwater clam *Corbicula fluminea*. We adopted the magnitudes of shell gape of 20% and 50% as the determining thresholds of valve closing and siphon extension statuses, respectively, to digitalize valve movements in bivalves for quantifying the characterization of valve behavioral rhythmic responses. The improved valvometry technique allows tested freshwater bivalves with a free-range spontaneous situation to avoid stresses from experimental artefacts, increasing their measurable sensitivity and reducing probability of abnormal closings. With reliable statistical modeling approaches, we linked proposed valve daily rhythmic models and the toxicodynamics-based Hill model to predict valve dynamic responses under different Cu exposures with a circadian valve rhythmic endpoint. Behavioral toxicity assays revealed Cu detection thresholds of 5.6 (95% CI: 2.1–9.3) mg l<sup>-1</sup> and 19.5 (95% CI: 14.6–24.3) mg l<sup>-1</sup> for response times of 300 and 30 min, respectively. Our findings reveal that when exposure Cu concentrations exceed 50 mg l<sup>-1</sup>, the differential degree of valve rhythmic response has a significant sensing ability within 30 min. The observation results demonstrate that our modeling approaches have robust prediction effects on describing valve rhythmic response variations. Our results implicate an early warning dynamic biomonitoring system that provides a potential *in situ* detection of waterborne Cu concentrations by circadian valve activities in *C. fluminea*, making it suitable for distinguishing the safe water resources in the site-specific areas.

## Ecological Consequences of Exposure to Pharmaceuticals (P)

## MO030

### Mechanistic considerations of ozone-amine-reactions

A. Tekle-Röttering, Westfälische Hochschule  
Agnes Tekle-Röttering, Winfried Schmidt, Torsten C. Schmidt  
Micropollutants in drinking water and wastewater are a matter of increasing concern. Many environmentally relevant compounds, e.g., pharmaceuticals or pesticides contain aromatic and aliphatic amino groups. Even at low concentrations, they may be harmful to aquatic organisms. In drinking water and wastewater treatment, micropollutant abatement by ozonation is gaining importance. There is, however, now also growing interest in the ozonation by-products and thus in the accountable mechanism. In this study the mechanism of ozone with anilines, nitrogen-containing aromatic heterocycles and nitrogen-containing aliphatic heterocycles as well water-soluble amines are compared. Ozone reacts strongly electrophilic and highly selective and one of the ozone-reactive site is the lone electron pair at nitrogen, which has to be accessible. Protonation reduces the otherwise high ozone reactivity and so reactivity depends on pH. A second potential site of ozone attack is the electron-rich aromatic ring (von Sonntag and von Gunten, 2012). In literature, several primary ozone reactions with miscellaneous compounds have been discussed (von Sonntag and von Gunten, 2012), so that miscellaneous conceivable primary processes (in reactions 1 - 5 a few examples are presented) can be suggested for the ozone-amine-reactions in aqueous solution: Addition (reaction 1), electron transfer (reaction 2) or insertion on the nitrogen or aromatic ring plus additional H-abstraction on the nitrogen (reaction 3) in the case of anilines and N-containing aliphatic heterocycles or at the aromatic ring in the case of anilines and N-containing aromatic heterocycles. The resulting highly reactive intermediates, like aminyl radicals, nitroxyl radicals, hydrotrioxide radicals, hydrogen peroxide radicals, amine radical cations or ozonide radical anions will undergo different reactions and the products that are formed in the ozone-amine reactions may indicate the initial mechanism. To what extent the miscellaneous reactions proceed, is reflected in ozone rate constants, ozone consumption and product yields and in addition was assessed by quantum-chemical calculations.

## MO031

Assessment of the biodegradability and ecotoxicity of the anti-cancer drug Imatinib mesylate after UV and simulated sunlight irradiation treatments  
C.A. Lutterbeck, Institute of Sustainable and Environmental Chemistry Faculty of Sustainability; E. Baginska, Leuphana Universität Lüneburg; J. Machado, University of Santa Cruz do Sul / Graduate Program in Environmental Technology; K. Kuemmerer, Leuphana University Lüneburg / Institute of Sustainable and

## Environmental Chemistry

As the anti-cancer drugs allow people to live longer with higher standards of living, the consumption of such compounds will increase and consequently their presence in the drinking and wastewater is also expected to rise. Imatinib (IM) is a cytostatic compound that was developed during the 1990s and has since then been used in large scale in the treatment of chronic myeloid leukemia and gastrointestinal stromal tumors. The presented study investigated the photodegradation of IM under UV and simulated sunlight irradiation as well as its biodegradability and toxicity before and after the treatments. An UV polychromatic lamp and a Xe lamp (simulating the sunlight spectrum) were used to perform the photodegradation experiments in a photoreactor containing 600 mL of a solution of IM at an initial concentration of 20 mg/L and prepared with ultrapure water. Irradiation was done for 256 min. After the irradiation, samples were submitted to biodegradation and ecotoxicity assays. The biodegradation experiments followed the guidelines of the OECD Closed Bottle Test (CBT), whereas the ecotoxicity assessment was carried out in accordance to a new automated method with the bioluminescent bacteria *Vibrio fischeri* which allows for the determination of the acute, chronic and growth toxicities (Menz et al., 2013). According to the biodegradation experiments IM has been classified as a non-biodegradable compound (< 8 %). The results showed that the parent compound IM did not undergo photolysis with the Xe lamp and was only a partially eliminated when using the UV lamp (48%). Furthermore, no significant mineralization (< 3%) was observed after the experiments performed with both lamps. Not surprisingly no differences were observed regarding the biodegradation and toxicity of the samples after been submitted to the irradiation with the Xe lamp, since no primary elimination was achieved after a treatment time of 256 min. The partially elimination of the parent compound when using the UV lamp did not improve the biodegradability or reduce the toxicity of IM. In conclusion, our study showed that other treatment options should be tested in order to eliminate IM and in this way improve its biodegradability and reduce its toxicity.

## MO032

### Pharmaceuticals in the environment: Biodegradation and effects on natural microbial communities

A. Barra Caracciolo, National Research Council / Water Research Institute; E. Topp, Agriculture and Agri-Food Canada (AAFC); P. Grenni, National Research Council of Italy (CNR) / Water Research Institute  
Environmental microorganisms play a key role in fundamental ecological processes such as biogeochemical cycling and organic contaminant degradation. Microorganisms comprise a large unexplored reservoir of genetic diversity and metabolic capability providing several ecosystem services, most importantly the maintenance of soil and water quality. Pharmaceutical occurrence in the environment can compromise microbial community structure and activities in different ways. The fate of a pharmaceutical in soil or water depends on numerous factors, including its inherent physico-chemical properties (e.g. water solubility, lipophilicity, vapour pressure), environmental factors and climate conditions (e.g. temperature, incident radiation, pH) and most importantly the presence and activity of microorganisms that possess the ability to biodegrade it. The presence of an active natural microbial community is a fundamental prerequisite for an effective response to contaminant presence in the various ecosystems. The recovery from contamination is only possible if toxicity does not hamper microbial activity. Current knowledge on the effects on natural microbial communities of some pharmaceuticals and of some biocides commonly found as environmental microcontaminants will be presented.

## MO033

### Electrochemistry-mass spectrometry for simulation of transformation processes of pharmaceuticals in the environment and electrosynthesis of their transformation products for risk assessment

L. Zhu, Forschungszentrum Jülich, ZEA-3 / ZEA; B. Santiago-Schübel, Forschungszentrum Jülich GmbH; H. Hollert, RWTH Aachen University / Institute for Environmental Research; S. Küppers, Forschungszentrum Jülich GmbH  
**1 Introduction:** Large amounts of pharmaceuticals are discharged into the environment per year and would undergo chemical and/or microbial transformations. However, the presence of these pharmaceuticals and their transformation products (TPs) might pose a potential risk to the environment as well as human beings. Risk assessment of these pharmaceuticals and their TPs requires a comprehensive understanding of their transformation in the environment. Moreover, most of these TPs are difficult to be achieved in mg levels for toxicity evaluation. Electrochemistry-mass spectrometry has been proven as a promising and efficient method to simulate the environmental transformation processes of pharmaceuticals in lab scale [1, 2]. Furthermore, electrochemical synthesis method could provide an alternative for the production of transformation products of these pharmaceuticals for risk assessment. Therefore, electrochemical methods offer a strategy for investigation of transformation and risk assessment of pharmaceuticals in the environment  
**2 Methods:** Online EC-MS was applied to simulate the transformation processes of the pharmaceuticals in the environment. The degradation voltages as well as mass spectrums for mechanism study were determined by using the EC-ESI MS/MS. For structure identification, high resolution FTICR-MS was used to determine the formula of relevant degradation products. Electrosynthesis of TPs was conducted in a “synthesis-cell” which is designed for small-scale electrosynthesis of mg quantities of compounds. The

toxicity evaluation was conducted in various bioassays, such as fish embryo tests, Ames test... In our study, a series of pharmaceuticals were investigated in the online EC-MS system. The transformation mechanisms of these compounds were studied. Their TP's were synthesized by electrochemical method in synthesis cell. After the sample preparation process, the ecotoxicity of the samples was evaluated in various bioassays. Risk assessment was conducted based on the toxicity evaluation data. **Reference** [1] Hoffmann, T., et al., Analytical and Bioanalytical Chemistry, 2011. **399**(5): 1859-1868. ### MO034

#### Effects of an antihistamine on litter decomposition in streams

M. Jonsson, Department of Ecology and Environmental Science; E. Ershammar, T. Brodin, Umea University / Department of Ecology and Environmental Science; J. Klaminder, Ecology and Environmental Science; J. Fick, Umea University / Department of Chemistry

Litter decomposition is important for regeneration of carbon (C) and nutrients in all ecosystems. In streams, microbe and invertebrate communities are the primary decomposers of terrestrially derived plant litter. Impacts on the decomposer community may therefore have consequences for C and nutrient cycling in the stream. Chemical contaminants, such as pharmaceuticals, may impact aquatic organisms. For example, antihistamines – used to treat allergies – have been found at very low concentrations in waters receiving wastewater effluence. Because invertebrates use histamines as neurotransmitters, exposure to low concentrations of antihistamines may affect their physiology. Hence, we wanted to investigate if low concentrations of an antihistamine affected decomposition in a running-water system containing leaf litter, microbes, and invertebrates (i.e. stonefly larvae). The experiment was carried out in a climate room over 31 days. As experimental chambers, we used 1-L aquaria with circulating water to mimic stream conditions. Half of these aquaria contained leaf litter (2 g) and microbes (10 mL inoculum), while the other half contained also 10 stonefly larvae. In each of these two treatments, half of the aquaria contained a 2 µg L<sup>-1</sup> concentration of the antihistamine fexofenadine, while the other half was used as a clean control. After termination, the stonefly larvae were counted and weighed, before being analyzed for antihistamine concentration. The leaf litter was dried and weighed to quantify mass lost to decomposition, and water samples (at start and termination) were analyzed for antihistamine concentration. Also, at termination, water samples were taken to analyze total organic carbon (TOC) and nitrogen (N) concentrations, as an additional measure of the decomposition process. Contrary to our expectations, there were no significant differences in stonefly survival or growth rate between the antihistamine and the control treatment. Further, the antihistamine had no effect on total litter decomposition, but a marginally significant *positive* effect on decomposition carried out by the stoneflies. However, importantly, both TOC and N concentrations were significantly lower in the antihistamine treatment, likely due to reduced microbial activity in response to antihistamine exposure.

### MO035

#### Determination of pharmaceuticals in sediments from the small stream dominated by effluent

O. Golovko, University of South Bohemia in CB / Lab of Environmental Chemistry Biochemistry; G. Fedorova, University of South Bohemia in CB / Faculty of Fisheries and Protection of Waters South Bohemian Research Center of Aquaculture and Biodiversity of Hydrocenoses Vodnany Czech Republic; O. Koba, University of South Bohemia in Ceske Budejovice / Faculty of Fisheries and Protection of Waters; T. Randak, University of South Bohemia in Ceske Budejovice Faculty of Fisheries and Protection of Waters / Laboratory of Environmental Chemistry and Biochemistry; R. Grabic, University of South Bohemia in CB / Faculty of Fisheries and Protection of Waters, South Bohemian Research Center of Aquaculture and Biodiversity of Hydrocenoses; R. Kodesova, Czech University of Life Sciences Prague / Dept of Soil Science and Soil Protection Simple and fast analytical method for determination of 130 pharmaceuticals was developed and validated. The selected pharmaceuticals belong to a great variety of different therapeutical classes: analgesics, β-blockers, antibiotics, anti-inflammatories, anticonvulsants, antidepressants and lipid regulators. The analysis was performed using liquid chromatography coupled to a triple quadrupole analyzer operated with tandem mass spectrometry. The sonication in different solvent: extraction mixture (acetonitrile and water (1/1, v/v, 0.1 % formic acid) and acetonitrile, 2-propanol and water (3/3/4, v/v, 0.1 % formic acid); acetonitrile and water (1/1, v/v, 0.1 % formic acid); acetonitrile, 2-propanol and water (3/3/4, v/v, 0.1 % formic acid); methanol and water (2/1, v/v) were tested. The best extraction method was applied for the analysis of pharmaceuticals in river sediments. The analysis showed a widespread occurrence of pharmaceuticals in the river sediments. The method allows high throughput analysis of pharmaceuticals in sediment with excellent sensitivity. Some target compounds were detected at very low concentration level (inferior to the ng/g). Acknowledgement: This study was supported by the project of the Czech Science Foundation (Project No. 13-12477S).

### MO036

#### The effects of antidepressants appear to be rapid and at environmentally relevant concentrations

A.T. Ford, University of Portsmouth / Biological Sciences; P.P. Fong, Gettysburg

### College

The effects of antidepressants of wildlife are currently raising some concern due to an increased number of publications indicating biological effects at environmentally relevant concentrations (< 100ng/L). These results have been met with some scepticism due to the higher concentrations required to detect effects in some species and the perceived slowness to therapeutic effects recorded in humans and other vertebrates. Since their mode of action is to modulate the neurotransmitters serotonin, dopamine, and norepinephrine, aquatic invertebrates that possess transporters and receptors sensitive to activation by these pharmaceuticals are potentially affected by them. We highlight studies on the effects of antidepressants, on particularly crustacean and molluscan groups showing they are susceptible to a wide variety of neuroendocrine disruption at environmentally relevant concentrations (pg-ng/L). Interestingly some effects observed in these species can be observed within hours of exposure. For example, exposure of amphipod crustaceans to several selective serotonin reuptake inhibitors (SSRIs) can invoke changes in swimming behaviour within hours. In molluscs, exposure to SSRIs can induce spawning in male and female mussels and foot detachment in snails within several hours of exposure. In the light of new studies indicating effects on the human brain with just of dose of SSRIs using MRI scans, we discuss possible reasons for the discrepancy in former results in relation to the “read-across” hypothesis, variation in biomarkers used, phylogenetic distance, and the affinity to different targets and differential sensitivity to receptors.

### MO037

#### Pharmaceuticals ecotoxicity: data curation and QSAR modeling

A. Sangion, DiSTA; S. Cassani, P. Gramatica, University of Insubria / DiSTA In the last decades pharmaceuticals have become a class of emerging potential pollutants since they are increasingly present in waste and surface water, air and soil. Due to their ubiquity present in the environment, the European regulatory agency on pharmaceuticals, EMEA (European Medicines Evaluation Agency), published, in 2006, a guideline for the environmental risk assessment of human pharmaceuticals that shall accompany the application for marketing authorisation. Like every risk assessment procedure, this guideline requires, for each chemical, a large amount of data as logKow, ecotoxicity, environmental fate, consumption and so on. Unfortunately ecotoxicological data are available only for a little percent of human pharmaceuticals in literature and databases; modeling approaches like those based on quantitative structure–activity relationships (QSARs) are valuable tools to maximize the information contained in existing experimental data and to predict missing information. However the quality and predictivity of a model depends on the quality of the data input according to the general rule of computer science GIGO (Garbage in, Garbage out). We checked big online databases like ECOTOX or OASIS and literature datasets looking for consistent ecotoxicological data on a set of more than 400 pharmaceuticals finding, in addition to good quality data, thousands of values for unspecified species, unspecified measured effect, unspecified time of exposure, undefined test condition and often with a wide range of experimental responses (even more than three order of magnitude) for the same chemical. In this study we present an example of data curation to prepare consistent datasets of pharmaceuticals with a clearly defined end-point according to the first OECD principle for QSAR modeling, verifying every chemical identifier and structure, organizing data for different end-point, effect measured, time of exposure and filtering inconsistent multiple different experimental data. Then we used these refined dataset to develop specific QSARs for different species representatives of a simplified aquatic ecosystem at different trophic levels in a preliminary aquatic toxicity study. Finally, predictions by different models were combined by Principal Component Analysis (PCA) to verify the toxicity trend and to screen and prioritize the most environmentally hazardous pharmaceuticals.

### MO038

#### Use of Acute and Chronic Ecotoxicity Data in Environmental Risk Assessment of Pharmaceuticals

J. Vestel, Merck & Co., Inc.; D.J. Caldwell, Johnson & Johnson; L.A. Constantine, Pfizer, Inc. / Pharmacokinetics Dynamics and Metabolism; V. D'Aco, Quantum Management Group, Inc.; T. Davidson, Bristol-Myers Squibb / EHS; D.G. Dolan; K. Kappler, Johnson & Johnson / Environmental Engineer; S. Millard, Probability Statistics and Information; R. Murray-Smith, AstraZeneca; J. Ryan, GlaxoSmithKline; J. Straub, F.Hoffmann-La Roche Ltd / Roche Group Safety Health Environmental Protection; P.W. Wilson, Sanofi U.S., Inc. / Health Safety and Environment

A team composed of representatives from 10 pharmaceutical companies was formed to evaluate the relationship between predicted no-effect concentrations (PNECs) calculated from acute EC<sub>50</sub> and chronic NOEC data derived from aquatic studies using standard regulatory assessment factors. Aquatic toxicity data for 102 active pharmaceutical ingredients (APIs) were compiled primarily from the companies' acute and chronic daphnid, fish and algae GLP validated studies, and supplemented with data from the peer-reviewed literature. These data encompassed a broad range of APIs in various therapeutic areas, with diverse modes of action, which were then classified according to the American Hospital Formulary Service (AHFS) classification scheme at the primary level. Additionally, the team characterized the relationship between aquatic toxicity and the *n*-octanol/water distribution coefficient (log Dow). Statistically significant but weak correlations were observed between increasing toxicity and increasing log Dow, indicating

other contributing factors to toxicity than Dow, particularly for green algae and blue-green algae. Adequate data to calculate both acute and chronic PNEC values were available for 57 of the APIs. For most compounds, PNECs calculated from acute data were lower than PNECs calculated from chronic data. Five of the 57 PNECs (9%) calculated from acute data were below the EU action limit of 0.01 ppb and all were classified as anti-infectives affecting algal species. Six of the 89 (6.7%) available PNECs calculated from chronic data were below the EU action limit and for all of these APIs fish were the most sensitive species. Analysis of these data suggests that the use of acute data to determine chronic PNECs are acceptable if chronic data are not available, unless specific mode of action concerns suggest otherwise (e.g. the API has known or suspected endocrine active properties).

#### MO039

##### **iPiE: Intelligence-Led Assessment of Pharmaceuticals in the Environment**

A. Boxall, University of York / Environment Department; R. Laenge, Bayer Pharma AG / Dept Experimental Toxicology; A. Coors, ECT Oekotoxikologie GmbH; J.R. Snape, AstraZeneca UK Ltd. / AstraZeneca Global Environment; F. Sanz, IMIM

A variety of human pharmaceuticals have been detected in the natural environment across the world. Although reported concentrations are generally low, many pharmaceuticals have been detected in a variety of hydrological, climatic, and land-use settings and some can persist in the environment for a significant time period. As these are biologically active compounds that are designed to interact with specific pathways and processes in target humans and animals, concerns have been raised about the potential effects of pharmaceuticals in the environment - , and over the past 15 years, a substantial amount of work has been done to determine the occurrence, fate, effects, and resulting risks of pharmaceuticals in the environment. Regulations have also been developed regarding the assessment of environmental risks of new pharmaceuticals within the market approval procedures. Currently, environmental assessments of pharmaceuticals are typically performed at the end of the development process, when the drug is close to an application for market approval. The identification of potential environmental concerns at such a late stage can merely describe the potential for environmental impact but cannot influence any early stage development or identification of specific targeted assessment strategies. -. Furthermore, concerns have been raised over whether the standard testing methods for examining chronic effects on organisms will identify ecologically important effects of specifically acting pharmaceuticals. There also is a need to address the legacy of existing APIs - more than 3,000 pharmaceuticals are currently in use yet data on the environmental risks is only available for a small proportion of these. iPiE is a 9.8 M Euro EC project, involving leading researchers from academia and the pharmaceutical industry, that aims to develop a framework (using information from toxicological studies, pharmacological mode of action and predictive models) for identifying the potential risks of human pharmaceuticals to the natural environment (considering both aquatic and terrestrial systems, including top predators). In the future this framework should be used to better target environmental testing requirements at an early stage in drug development programmes and for prioritising legacy pharmaceuticals for experimental testing and monitoring.

#### MO040

##### **Post-Approval Environmental Stewardship of Tamoxifen**

K. Hutchinson; R. Murray-Smith, AstraZeneca; J.R. Snape, AstraZeneca UK Ltd. / AstraZeneca Global Environment

Tamoxifen is an anti-oestrogen drug that is widely used to treat breast cancer. Tamoxifen is an established product that pre-dates current EU regulatory requirements for environmental risk assessment (ERA). It is highly metabolized in the liver, and both tamoxifen and its metabolites are excreted and released into the aquatic environment. Through our post-launch Ecopharmacovigilance initiative we have collated data points and information from AstraZeneca studies and published literature on the effects of tamoxifen on a range of aquatic species, together with information on the predicted fate and exposure of tamoxifen and measured concentrations in various environmental media. This poster will present a comprehensive summary and analysis of all the published data available for tamoxifen and an assessment of the environmental risks.

#### MO041

##### **Monograph System for environmental data of active pharmaceutical substances: necessity, challenges and perspectives**

I. Rönnefahrt, Federal Environment Agency / Section IV Environmental Risk Assessment of Pharmaceuticals

Even more than 10 years after implementing the environmental risk assessment (ERA) into the European pharmaceutical legislation there is still a lack of data on fate and effects of active pharmaceutical substances. The reason for that is quite simple: A review program of 'legacy' products, which were approved before the ERA requirement was set, was never envisaged. In the pre-market phase an environmental risk assessment is required for all new applications. This leads to duplication of data and of assessments. Due to the fact that results of fate and effect studies may vary, this may also lead to contradictory assessments and even to different risk mitigation measures for medicinal products intended for the same indication. This is not acceptable, neither from an scientific nor from an economic point of view. The described problems with the functioning of the current

legislation could largely be solved with the establishment of a monograph system on active pharmaceutical substances. The aim of a monograph system is to collate existing fate and effects data on active pharmaceutical substances, to generate missing data, to evaluate studies and to agree on the endpoints to be used for ERAs of medicinal products. Once established all authorizations of medicinal products would use the agreed endpoints from the monograph of the respective active substance to perform the environmental risk assessment of the product. A monograph on fate and effects data would have a lot of benefits regarding the efficiency of the authorization procedure of medicinal products. Overall, only a pre-market monograph system in conjunction with an effective monitoring within the post-market surveillance will be able to ensure the environmental safety of veterinary medicinal products in use. Environmental data collated in monographs should regularly be adapted to the scientific and technical progress. This is essential to ensure up-to-date risk assessments of veterinary medicinal products. Therefore monographs on active pharmaceutical substances will be the key measure to ensure the environmental safety of veterinary medicinal products in use. Challenges for the establishment of a monograph system are first of all clear rules on set up and management of consortia, rules on data protection, cost sharing etc.. Examples of successful collaborations already exist in other legislative areas like REACH and biocides.

#### MO042

##### **Environmental risk assessment of pharmaceuticals and endocrine disruptors in surface waters of the State of Sao Paulo (Brazil)**

J.C. López-Doval, University of São Paulo / Depto de Ecologia Laboratório de Limnologia; M. Pompêo, University of São Paulo

While in the USA and Europe the knowledge on the presence and possible environmental risks of emerging pollutants is wide, in developing countries it is still scarce. In Brazil the number of studies on this issue is not as extensive as in Europe and USA and these few studies are mainly geographically focused in the State of Sao Paulo (SP). The objective of this work is to assess the environmental risk of pharmaceuticals and endocrine disrupting compounds (EDCs) detected in freshwaters of SP. For that, published data on concentrations of these compounds was used. In order to include data published in local scientific journals, the search was performed with Google scholar. A total of 8 articles studying concentrations of these substances were included, these papers covered a period from 2005 to 2014. Concentrations of pharmaceuticals and EDCs were measured by authors in 7 different rivers and 2 reservoirs. Using these data, risk assessment was calculated individually for each paper. For pharmaceuticals, potential risk of the mixture was calculated for fish, *Daphnia magna* and algae in base to Hazard Quotients (HQ). HQ for all the mixture was calculated as the summatory of the values obtained dividing the higher concentration found for each compound detected in the respective study by a specific risk factor (EC50 value of the substance/1000, as PNEC). In the case of EDCs, the potential estrogenic activity of the mixture was calculated as the summatory of the value obtained multiplying the higher environmental concentration of each estrogenic substance by a relative estrogenicity factor for this substance. Both values of EC50 and estrogenicity factor were obtained from literature and based on experimental data. Environmental risk for pharmaceuticals was detected in two studies for algae and crustaceans. HQ values ranged from 0.002 to 585. Risk for EDCs was presented in only 2 studies, but showing high possible estrogenic activity. The papers used in this work, reported high concentrations of pharmaceuticals and EDCs in freshwater ecosystems, maybe due to the lack of advanced sewage treatment and uncontrolled spills. By the first time, this work evidences potential risk for biota due to the presence of these substances in Brazilian freshwaters. Further in situ studies should be developed to confirm deleterious effects on biota.

#### MO043

##### **Pharmaceuticals in the Environment: global occurrence, effects, and potential cooperative action**

S. Hickmann; T. aus der Beek, IWW Water Centre; I. Ebert, Umweltbundesamt / Pharmaceuticals Department; J. Koch-Jugl, Federal Environment Agency / International Chemical Management; A. Hein, Federal Environment Agency (UBA) / Section IV Pharmaceuticals; A. Kuester, Environmental Risk Assessment; F. Weber, IWW Rheinisch-Westfälisches Institut fuer Wasser / Bereich Wasserressourcen-Management; J. Rose, Umweltbundesamt

The poster presents results of an extensive literature research on the global occurrence of pharmaceuticals in the environment. Data on measured environmental occurrences from more than 1,000 international publications have been transferred to a database, with more than 120,000 entries. According to the database, pharmaceuticals have been found in the environment of 71 countries worldwide in all five UN regions. Most published data are for the compartments surface water and sewage effluent; less information is available for groundwater, manure, soil, and other environmental matrices. More than 600 active pharmaceutical substances (or their metabolites and transformation products) have been detected in the environment. Most findings have been published for industrialized countries. Monitoring campaigns are increasingly being conducted in developing and emerging countries. These have revealed the global scale of the occurrence of pharmaceuticals in the environment. For example, diclofenac, a non-steroidal inflammatory drug, has been detected in the aquatic environment in 50 countries worldwide. A number of globally marketed pharmaceuticals have been

found in both developing and industrialized countries. The available ecotoxicological information indicates that certain pharmaceuticals pose a risk to the environment at measured concentrations. Options for cooperative action to address the risk of are also presented. The aim of the research presented was to support the discussion of the proposed emerging policy issue pharmaceuticals in the environment under the Strategic Approach to International Chemicals Management (SAICM), which is a global initiative of United Nations Environment Programme (UNEP).

#### MO044

##### **Prioritisation of pharmaceuticals and metals - literature vs laboratory**

R.L. Donnachie, E. Gozzard, Centre for Ecology and Hydrology; J. Ojogoro, Brunel University; M.D. Scrimshaw, Brunel University / Institute for the Environment; A.C. Johnson, CEH Wallingford / Wallingford; J.P. Sumpter, Brunel University / Institute for the Environment

Thousands of pharmaceuticals are entering our aquatic environment every day but which ones pose the greatest risk? We do not have the time or resources to assess the environmental risk from every pharmaceutical to the level of detail we would like. This forces us to consider different prioritisation approaches. This study has the long term aim of prioritising all chemical groups on the basis of risk through analysis of the literature. Twelve key pharmaceuticals were identified by selecting those most frequently cited by the scientific community in literature risk rankings using such factors as annual consumption, persistence, potency and predicted fish plasma concentrations. The twelve, which emerged most frequently, were Ibuprofen, Diclofenac, Paracetamol, Carbamazepine, Naproxen, EthinylEstradiol (EE2), Propranolol, Atenolol, Sulfamethoxazole, Metoprolol, Ofloxacin and Fluoxetine. These twelve pharmaceuticals were ranked by risk through comparing all literature ecotoxicity effect values with those either reported or predicted in UK water courses. As part of the greater study, this same approach was also used for the metals although in this case a representative sub-set of the ecotoxicity literature was used. The ranking compares the median ecotoxicity concentration with the median river water concentration. Overall, the metals emerged as a greater risk to aquatic wildlife than the pharmaceuticals. The pharmaceutical identified as the greatest risk using this approach was EE2. As a reality check on this literature based risk-ranking analysis, the toxicity of selected metals and pharmaceuticals were compared in our laboratory using *Pseudokirchneriella subcapitata* and *Daphnia magna* MicroBioTests. In theory, the ranking of these selected chemicals on the basis of toxicity to an alga and daphnid should match that from the literature survey. Here we will report how the two compared.

#### MO045

##### **Risk based prioritization of human pharmaceuticals in Korea water environment**

K. Ji, Yongin University; E. Han, Seoul National University; J. Park, SOON CHUN HYANG UNIVERSITY / College of Natural Sciences; J. Ryu, National Institute of Environmental Research / Risk Assessment Division; K. Choi, Seoul National University / School of Public Health

Pharmaceuticals have been used for protection of human and animal health, however their residues in the aquatic environment are potential threat to ecosystem health. In order to identify high priority pharmaceutical residues in terms of ecological risks, several prioritization schemes have been proposed to date. However, most of previous approaches are focused on the level of environmental occurrences or the amount of use. We proposed a prioritization strategy that considered both the levels of environmental occurrence and the potential hazards of the human pharmaceuticals in Korea. A total of 695 human active pharmaceutical ingredients (APIs) were first screened by logKow, annual production volume, and predicted environmental concentrations (PECs). Annual production volume of the target APIs were derived from drug production statistics of Korea as of 2011. PECs were derived in Han River of Korea by use of pharmaceutical assessment and transport evaluation (PhATE™) program. In addition to the number of pharmaceuticals screened for high ambient occurrence levels, major antineoplastic drugs and hormones were included in the initial list because of their high potential of toxicity. Then, the final lists of priority pharmaceuticals were derived based on the hazard quotient of each APIs. Probuco (logKow>3.5), tamoxifen (antineoplastic drugs), norethisterone (hormones), and 17 $\alpha$ -ethynylestradiol (synthetic hormones) were selected as final lists. Because of their low or often seemingly negligible levels of occurrence in ambient water, these pharmaceuticals have neither been adequately monitored nor assessed for risks. Further efforts are warranted to understand their risk potentials in the aquatic environment of Korea.

#### MO046

##### **How to prioritise veterinary pharmaceutical substances for a monograph system?**

I. Ebert, Umweltbundesamt / Pharmaceuticals Department; A. Hein, Federal Environment Agency (UBA) / Section IV Pharmaceuticals

The poster presents a new and manageable prioritising concept for veterinary pharmaceutical ingredients (VPIs) intended for inclusion in a currently discussed monograph system as a starting point for further discussions. There are 400-600 active veterinary substances on the European market. Only a limited amount of these are environmentally relevant and must be considered in the intended monograph system for VPIs. Therefore, it is necessary to prioritise. Our

prioritisation concept aims to identify the substances that have the highest potential environmental risk and/or the highest potential presence in the environment. We propose a simple, three-step method, which is based on the EMA/VICH Guideline for the environmental risk assessment of veterinary pharmaceuticals considering substance specific information on consumption, exposure, fate and effects available to a German regulatory authority. The proposed method classifies the substances into 4 priority categories, which reflect the potential environmental relevance and thus the priority for inclusion in a monograph system. The goal of our work was to determine few and relatively simple criteria for a rough classification of active ingredients for which monographs should be compiled first. Prioritisation, exemplarily done on the basis of data available for Germany has shown that most of the active substances are expected to be in class II (high priority) and class III (moderate priority). Parasitocides and antibiotics turned out to be the environmentally most relevant substances. The suggested method is considered to be transferable to other EU countries because all base data necessary for prioritisation should be available to other national regulatory authorities as well.

#### MO047

##### **Prioritization of veterinary antibiotics for higher-tier environmental fate and effect analysis using a simple screening approach**

J. Menz, J. Müller, M. Munck, Leuphana University Lüneburg / Institute of Sustainable and Environmental Chemistry; S. Gottschalk, Leuphana University; K. Kuemmerer, Leuphana University Lüneburg / Institute of Sustainable and Environmental Chemistry

Veterinary antibiotics (VAs) are widely recognized as important environmental contaminants and are frequently detected in environmental samples throughout the recent years. The environmental occurrence, fate and effects of VAs are strongly dependent on varying local factors, which is why region-specific priorities for environmental risk assessment (ERA) should be established. Moreover, substance prioritization in ERA of VAs is usually based on predicted or measured environmental concentrations, whilst the intrinsic antimicrobial activity of VAs is often not considered. In this context, a more integrated screening procedure was developed and exemplarily applied in a case study of northwestern Germany. The first level (A) included a comprehensive usage pattern-based exposure screening (UPES) to identify environmentally relevant substance candidates on the basis of VA consumption data. The identified candidates were subjected to a biodegradability screening (level B) using a modified closed bottle test (CBT), which allows identifying false negative results due to antimicrobial effects of the test substance with a considerably improved reliability compared to the standard CBT (OECD 301D). Finally, the toxicity towards soil bacteria (level C) of non-readily biodegradable VAs was evaluated in a modified contact assay for the long-term exposure. After screening level A, 7 VAs (Amoxicillin, Chlortetracycline, Colistin, Enrofloxacin, Sulfadiazine, Tetracycline and Trimethoprim) were identified as high-priority substances. These candidates were further classified as not readily biodegradable or highly toxic to heterotrophic microorganisms in screening level B and hence might persist in the environment in an active form. Therefore, the toxicity towards the soil bacteria species *Pseudomonas putida* and *Bacillus amyloliquefaciens* of selected substances was assessed in screening level C, which revealed strong variations between the analyzed compounds in terms of antimicrobial activity, species selectivity and bioaccessibility in presence of bulk soil. With this simple screening approach we were able to prioritize VAs under consideration of the regional environmental relevance, biodegradability and intrinsic antimicrobial activity. Therefore we conclude that a more integrated initial screening is especially useful for the regional priority-setting in ERA of VAs and might help to address existing research gaps more adequately.

#### MO048

##### **Ecotoxic and genotoxic effects of last-resort and broad-spectrum antibiotics - fate and behavior of potential future micropollutants in aquatic systems**

J. Bruensing, W. Dott, RWTH Aachen University / Institute of Hygiene and Environmental Medicine; H. Hollert, RWTH Aachen University / Institute for Environmental Research; J. Bressling, Institute of Environmental Engineering, RWTH Aachen / Institute of Hygiene and Environmental Medicine

Pharmaceuticals and their metabolites have been emitted in large amounts to the aquatic environment for many years, mostly as complex mixtures in the effluents of sewage treatment plants and sludge. For a precocious identification and assessment of environmental risk after launching new pharmaceutical substances, two last-resort antibiotics (Linezolid and Tigecyclin) and one broad-spectrum antibiotic (Doripenem), which are used in the treatment of severe infections, were selected. For the detection of eco- and genotoxicological effects, stock solutions with a given amount of each antibiotic were prepared and stored at 4 degrees in the dark to prevent photolysis. Ecotoxicological testing was performed within 24 hours with a dilution series of stock solutions using standardized bioassays, such as the algal growth inhibition assay with *Desmodesmus subspicatus* and *Daphnia magna* Straus immobilization test. Genotoxicity was determined with two bacterial short-term tests based on the induction of the emergency repair (SOS) response as a direct relation to the degree of DNA damage. The SOS test assay was performed with *E. coli* PQ37, the *umu* test with *Salmonella choleraesuis* subsp. *chol*. TA1535/pSK1002. The test systems were conducted consistently with and without metabolic activation using 96-well microplates. Biodegradability of antibiotic

substances in aqueous systems was determined with the combined and optimized test system "O<sub>2</sub>/CO<sub>2</sub>-Headspace Test" with GC-TCD following standard procedures (ISO) with modifications for measurement of the ultimate aerobic mineralization of test substances to carbon dioxide in water. The last-resort antibiotic Tigecyclin was evaluated as "good (ready) biodegradable", since degradation was exceeded 60% within 28 days. In contrast Linezolid was non-biodegradable. There were no ecotoxic effects for the broad-spectrum antibiotic Doripenem. The antibiotic Tigecyclin showed the highest ecotoxicity in the algae test (EC<sub>50</sub> 3.4 mg/L) with maximum test concentration of 200 mg/L. For the daphnia immobilization assay Linezolid showed highest toxicity (EC<sub>50</sub> 160.4 mg/L). Contrary to ecotoxicity there was no genotoxicity for Linezolid. Genotoxicological effects were detected for Doripenem and Tigecyclin with and without metabolic activation ranging from 1 to 100 mg/L.

#### MO049

##### **In vitro metabolism and metabolite identification of select antibiotics, propranolol and diclofenac by rainbow trout (*Oncorhynchus mykiss*) liver S9 fractions**

M. Denadai; K.A. Connors, US Environmental Protection Agency / ORDNCCT; A.J. Ramirez, Baylor University / Baylor Science Facility; C.K. Chambliss, Baylor University; P. Fitzsimmons, U.S. EPA.; J.W. Nichols, U.S. Environmental Protection Agency; Q.B. Cass, Universidade Federal de São Carlos / Química; B.W. Brooks, Baylor University / Dept of Environmental Science  
Extensive use of antibiotics in agriculture is becoming an emerging environmental and public health concern at the global scale. Whereas physico-chemical properties and biological activities of pharmaceuticals present challenges to historical environmental assessment and management, an understanding of pharmaceutical bioaccumulation in aquatic life remains limited, particularly for veterinary medicines. Performing *in vivo* fish bioconcentration studies for all pharmaceuticals is impractical in a timely fashion due to high costs, animal welfare and other considerations. Herein, *in vitro* models, including fish S9 substrate-depletion assays, promise to support screening level bioaccumulation assessments of environmental contaminants, and then trigger more intensive whole organism experiments. The primary objective of the present study was to determine *in vitro* biotransformation of select antibiotics used in aquaculture, and the common pharmaceuticals propranolol and diclofenac, using a substrate depletion approach. Following previously reported methods from our research team S9 fractions from rainbow trout (*Oncorhynchus mykiss*) liver were characterized and then used to carry out these experiments. Five major antibiotics used in aquaculture were selected: oxytetracycline, enrofloxacin, florfenicol, sulphadimethoxine and trimethoprim. Propranolol and diclofenac, for which we recently reported biotransformation using this approach, were selected as positive controls. Depletion of each parent compound was monitored by liquid chromatography–high resolution mass spectrometry (LC–HRMS) using a Thermo Fisher Orbitrap. High resolution data-dependent MS/MS spectra were employed for identification of metabolites with high sensitivity and accurate mass. Our findings indicate that hepatic biotransformation rates of these antibiotics were not significant *in vitro*. However, substrate depletion of propranolol and diclofenac were again observed, and their primary metabolites were identified. We then compared these metabolites to similar profiles in humans. Our results suggest that this approach is particularly promising for screening and identification of pharmaceutical metabolites in fish.

#### MO050

##### **Effect of erythromycin exposure in *Oncorhynchus mykiss* gills and liver: detoxification mechanisms, oxidative defence system and peroxidative damage.**

S. Rodrigues, Oporto University / Biology; S. Antunes, University of Oporto / Biology; C. Moreira, CIIMAR University of Porto; A.T. Correia, CIIMAR and Faculdade de Ciências da Saúde da Universidade Fernando Pessoa; B. Nunes, CESAM University of Aveiro

The increasing presence of pharmaceutical drugs in the wild, especially in the aquatic environment, is cause of concern due to the occurrence of deleterious effects, including oxidative stress, in non-target species. Erythromycin (ERY) is a macrolide antibiotic, which is widely used as an antibacterial agent. ERY is widely used in human therapeutics, but also in aquaculture practices. Due to its frequent usage, ERY was already detected in surface waters, in levels between several ng/L to µg/L. Recent studies have indicated unintended biological activity of ERY on non-target organisms, at different levels of biological organization. The present study aimed to assess the toxic effects of ERY in *Oncorhynchus mykiss* exposed during 28 days, under realistic levels of exposure (0.05 – 0.80 µg/L). In order to evaluate the ERY effects in the rainbow trout, gills and liver were analyzed with biochemical markers, such as catalase (CAT), total glutathione peroxidase (GPx), glutathione reductase (GRed) and glutathione-S-transferases (GSTs) activities, and also lipid peroxidation levels (TBARS). Concerning the antioxidant responses measured in gills and liver, it was possible to observe alterations that were more evident in gills than in liver, after erythromycin exposure. Catalase quantification in gills showed a significant decrease of this enzyme's activity in fish exposed to 0.05 and 0.8 µg/L. Our results showed that glutathione peroxidase activity was significantly increased only in gills of organisms exposed to 0.20 and 0.40 µg/L. No significant alterations were observed in GRed activity in gills and liver. Significant differences in GSTs activity were also found in gills after 0.1 - 0.8 µg/L ERY

exposures. A significant increase in lipid peroxidation levels (shown by higher TBARS levels) occurred in gills, with the increase of erythromycin concentrations. It is thus possible to hypothesize that the higher level of TBARS constitute an indication of stress in cellular redox status (GPx and GST activities increased) mainly in gills, due to their physiological function of barrier and detoxification organ. The results obtained for liver tissue may be due to poor absorption of ERY, or to an overexpression of the enzymatic defense in gill tissue, thus preventing the establishment of an oxidative response in other tissues (such as liver).

#### MO051

##### **Genotoxicity responses of environmental concentration of Oxytetracycline on fishes through micronucleus test and nuclear abnormalities**

R.G. Botelho, University of São Paulo / Ecotoxicology; C.A. Christofoletti, Fundacao Herminio Ometto / Environmental Mutagenesis; Y. Ansoar, Unesp / Bi; J.E. Correia, Universidade Estadual Paulista Julio de Mesquita Filho / Environmental Mutagenesis; v. tornisielo,

Oxytetracycline (OTC) is one of most commonly used antibiotic for the treatment of bacterial in fish farming in Brazil, and because of their intensive use, the potential harmful effects on aquatic animals are a great concern. In this study was evaluated the effect of environmental concentration of OTC on the genetic material of the juveniles of Tilapia (*Oreochromis niloticus*) erythrocytes by using occurrence of micronucleus (MN) and others erythrocytic nuclear abnormalities (ENAs). In a previous study at our laboratory the concentration 8,000 ng L<sup>-1</sup> was found in a Brazilian fish farming by Online-Liquid Chromatography coupled to Mass Spectrometry, and in the present study young of *O. niloticus* were exposed to this concentration, plus its half (4,000 ng L<sup>-1</sup>) and the double (16,000 ng L<sup>-1</sup>). The experimental design was composed of a repetition for each concentration and negative (NC) and positive controls (PC) with 6 fish in each, totalizing 12 fish per treatment. At the final of the test (96 hours), blood from all fishes (n=12 per treatment) were collected by cardiac puncture dripped on microscopic glass slides and fixed with ethanol for 10 min and then stained with 5% Giemsa for 20 min. Three slides were prepared for each fish (n=5) of each concentration. From each slides a thousand erythrocyte cells (3,000 per fish) were analyzed under 1000x magnification through a light microscope and the images captured with a camera connected. ENAs were classified in three groups such as blebbed nuclei (BN), notched nuclei (NN), and lobed nuclei (LN). MNs were not registered in erythrocytes of *O. niloticus* after exposure to OTC and its respective NC and PC. Occurrence of ENAs were low and the most frequently ENA observed was NN. Significant differences were observed between PC and the lower concentration of OTC compared to NC (p≤0.05). Statistical differences were observed when compared the intermediate and the higher concentration of OTC and PC (p≤0.05). No statistical differences for BN were observed for the three concentrations of OTC and PC when compared to NC (p≤0.05) as well as for LN when compared the three concentrations of OTC and NC (p≤0.05). Statistical differences were observed when compared the intermediate and the higher concentrations of OTC in relation to PC (p≤0.05). In conclusion the environmental concentration of OTC and its half and double are not genotoxic to *O. niloticus* according to the MN test and ENAs.

#### MO052

##### **Evaluation of Environmentally Relevant Concentrations of Oxytetracycline on Fishes using the Comet Assay**

R.G. Botelho, University of São Paulo / Ecotoxicology; J.E. Correia, Universidade Estadual Paulista Julio de Mesquita Filho / Environmental Mutagenesis; C.A. Christofoletti, Fundacao Herminio Ometto / Environmental Mutagenesis; Y. Ansoar, Unesp / Bi; v. tornisielo,

Livestock production is one of the most expressive activity of Brazilian agribusiness. However, to increase the productivity and competitiveness, the use of drugs with therapeutic and prophylactic purposes is a common practice. In Brazil, the fish farming, is one of the most important sector for the economy and which has been associated with negative impacts on aquatic environments due to the intensive use of these compounds. Oxytetracycline is one of the most commonly used antibiotic in Brazilian fish farming and thus, is very important to conduct toxicity test to verify how dangerous is this compound since a poor literature is available. Thus, the goal of this work was to evaluate the genotoxic response of environmentally relevant concentrations of oxytetracycline to tilapia (*Oreochromis niloticus*) using the comet assay. In a previous study at our laboratory the concentration 8 µg L<sup>-1</sup> was found in a Brazilian fish farming by Online-SPE-Liquid Chromatography coupled to Mass Spectrometry, and in the present study young of *O. niloticus* were exposed to this concentration, plus its half (4 µg L<sup>-1</sup>) and its double (16 µg L<sup>-1</sup>). The experimental design was composed of a repetition for each concentration and negative and positive controls with 6 fish in each. After 96 hours exposure, blood from all fishes (n=12 per treatment) were collected by cardiac puncture, submitted to the comet assay in alkaline version (pH>13) under specific conditions for ADN denaturation, electrophoresis (running time: 20 min; Voltage: 39V and amperage 300 A) and then stained with GelRed. Comets were analyzed by visual methodology, considering the frequency of cells with or without damage, the score and the distribution of class. Kruskal-Wallis with p<0.05 was used to compare the ADN damages between the groups treated with antibiotics and negative control. After the exposure time, ADN damages caused by environmentally concentrations of oxytetracycline showed to be dose-dependent with the lower concentration presenting no damage and the intermediate and the

higher concentrations presenting higher damages.

#### MO053

##### **Genotoxicity potential of environmental concentration of Florfenicol on fishes through micronucleus test and nuclear abnormalities**

V. Tornisielo, R.G. Botelho, University of São Paulo / Ecotoxicology; J.E. Correia, Universidade Estadual Paulista Julio de Mesquita Filho / Environmental Mutagenesis; C.A. Christofolletti, Fundacao Herminio Ometto / Environmental Mutagenesis; Y. Ansoar, Unesp / Bi

Florfenicol is one of most commonly used antibiotic for the treatment of bacterial in fish farming in Brazil, and because of their intensive use, the potential harmful effects on aquatic animals are a great concern. In this study was evaluated the effect of environmental concentrations of FLC on the genetic material of the juveniles of Tilapia (*Oreochromis niloticus*) erythrocytes by using occurrence of micronucleus (MN) and others erythrocytic nuclear abnormalities (ENAs). In a previous study at our laboratory the concentration 425 ng L<sup>-1</sup> was found in a Brazilian fish farming by Online-Liquid Chromatography coupled to Mass Spectrometry, and in the present study young of *O. niloticus* were exposed to this concentration, plus its half (212.5 ng L<sup>-1</sup>) and the double (850 ng L<sup>-1</sup>). The experimental design was composed of a repetition for each concentration and negative (NC) and positive controls (PC) with 6 fish in each, totaling 12 fish per treatment. The exposure duration was 96 hours. At the final of the test, blood from all fishes (n=12 per treatment) were collected by cardiac puncture dripped on microscopic glass slides and fixed with ethanol for 10 min and then stained with 5% Giemsa for 20 min. Three slides were prepared for each fish (n=5) of each concentration. From each slides a thousand erythrocyte cells (3,000 per fish) were analyzed under 1000x magnification through a light microscopic and the images captured with a camera connected. ENAs were classified in three groups such as blebbed nuclei (BN), notched nuclei (NN), and lobed nuclei (LN). MN mean registered in fish erythrocytes after exposure and its respective NC and PC ranged from 0.02 ± 0.16 (425 ng L<sup>-1</sup>) to 0.30 ± 0.64 (PC). No statistical differences were observed between the concentrations and the NC (p≤0.05). NN was the most commonly ENAs detected and statistical differences were observed between all concentrations and PC compared to the NC (p≤0.05). No statistical differences were noted for BN (p≤0.05). Regarding LN statistical differences were registered for the lower and the higher concentrations compared to the NC (p≤0.05). Environmental concentration of FLC (425 ng L<sup>-1</sup>) and the other tested (half and double) promoted DNA damage in *O. niloticus*, and thus, it is not safe to aquatic environments.

#### MO054

##### **Evaluation of DNA damage induced by acute and chronic exposures of the freshwater fish species *Oncorhynchus mykiss* to the antibiotic drug erythromycin**

S. Rodrigues, Oporto University / Biology; S. Antunes, University of Oporto / Biology; M. Rodrigues, Departamento de Biologia da Universidade de Aveiro; A.T. Correia, CIIMAR and Faculdade de Ciências da Saúde da Universidade Fernando Pessoa; B. Nunes, CESAM University of Aveiro

The use of pharmaceutical drugs has increased substantially, and lead to the use of several substances with antibiotic activity in common practices of human and veterinary medicines. Residues of antibiotics have been found in aquatic environments, but their effects on fish have not been thoroughly studied. Recent studies have indicated unintended biological activity of erythromycin on non-target organisms, at different levels of biological organization. The possible genotoxic effects of erythromycin have not been well studied in aquatic organisms, particularly in fish, which are vulnerable to exposure to environmental contaminants of this type. Fish erythrocytes are considered as a major site for ROS production due to their role in the oxygen transport via hemoglobin as wells as due to oxygen utilization. Moreover, since toxic chemicals are absorbed and then transported through the bloodstream, they contact directly with erythrocytes, which in turn are among the first cells to suffer toxic effects. This work assessed the effects of the antibiotic erythromycin on rainbow trout (*Oncorhynchus mykiss*), after acute (0.001, 0.010, 0.100, 1.000 and 10.00 mg/L) and chronic (0.05, 0.10, 0.20, 0.40 and 0.80 µg/L) exposures. Genotoxic endpoints, reflecting different types of genetic damage, were adopted, and comet and erythrocytic nuclear abnormalities (ENAs) assays were performed. The obtained results indicate that the exposure to erythromycin induced DNA damage in blood cells of rainbow trout. Fish exposed to erythromycin revealed a significantly higher DNA damage, measured as *Genetic Damage Index* -GDI, after both acute (0.010, 0.100, 1.000 and 10.00 mg/L) and chronic (0.2 and 0.8 µg/L) exposures. Globally, the GDI results were concentration-dependent in acute exposure. Significant alterations were found in ENA frequency following the acute exposure to erythromycin. So, an increased tendency for the occurrence of damage was perceptible in all concentrations, relatively to control. After chronic exposure, significant results were observed only at the highest concentration. From the analysis of the comet assay results, the erythromycin potential to induce DNA strand breaks in blood cells became clear. Considering ENA assay, the erythromycin capacity to cause chromosome breakage and/or chromosome segregational abnormalities was demonstrated.

#### MO055

##### **Embryonic exposure of zebrafish to two antibiotics commonly used in Brazil - the case of study of sulfasalazine and nitrofurantoin**

R.C. Carlyle Silva de Oliveira, Laboratory of Genetics and Toxicology / Departamento de Genética e Morfologia; D.S. Moura, Universidade de Brasília / Genética e Morfologia; R. Oliveira, University of Brasília / Department of Genetics and Morphology; C.K. Grisolia, University of Brasília / Department Genetics and Morphology

Pharmaceuticals are essential for the human and animal health. Antibiotics are among the most extensively used pharmaceuticals worldwide. They are natural or synthetic drugs with the capacity to kill or inhibit the growth of microorganisms being mainly used in hospitals, agricultural fields, and livestock production facilities. Antibiotics can be administered to treat or prevent diseases as a prophylactic measure. Due to its high usage, relative persistence and constant input through effluents the antibiotic have been detected in several aquatic environments. The objective of this study was to evaluate the embryotoxic effects of sulfasalazine and nitrofurantoin using zebrafish embryos as model organisms. The toxicity tests were based in an extended version of the OECD protocol No. 236 - Fish Embryo Toxicity (FET) test. For each drug were prepared seven concentrations: 0, 1; 3.2; 10; 31.6; 100; 316.2; 1000 mg/L for sulfasalazine; and 0, 1; 2.2; 4.6; 10; 21.5; 46.4; 100 mg/L for nitrofurantoin. A total of sixteen organisms per concentration were divided in three replicates (each replicate consist in a 24-well microplates filled up with 2 ml of test solutions). Developmental abnormalities, hatching, behaviour and mortality were evaluated during the experiment. In summary, the results of nitrofurantoin test (96h-LC50 > 100 mg/L) indicate low toxicity of this compound. Only a slight effect on equilibrium and hatching was noticed. Sulfasalazine also showed low toxicity to zebrafish embryos with a 96h-LC50 > 100 mg/L but a dose response to hatching and developmental parameters were observed. The results of this study showed that a short-term exposure of zebrafish to sulfasalazine and nitrofurantoin can provoke alterations in the normal developmental of zebrafish only at high concentrations. Thus, adverse effects of the studied antibiotics are not expected to occur in natural ecosystems.

#### MO056

##### **Chronic effects of cephadrine and cefadroxil, two veterinary antibiotics, on aquatic organisms**

B. Kim, Department of Environmental Health; K. Ji, Yongin University; J. Ryu, National Institute of Environmental Research / Risk Assessment Division; P. Kim, National Institute of Environmental Research; K. Choi, Seoul National University / School of Public Health

Veterinary medicines are frequently used to protect animal health, however these pharmaceuticals could enter the environment through direct application in aquaculture, runoff from manure-treated farmlands, or wash-off from topical treatments as nonpoint source pollutants. While many of these compounds have been frequently detected in freshwater environment worldwide, their toxicological information is often limited. In the present study, the adverse effects of chronic exposure to cefadroxil and cephradine, two cephalosporin antibiotics for animals, were evaluated using *Daphnia magna* and *Danio rerio*. These antibiotics have been detected in high frequency in areas nearby large animal farms of Korea, but relevant ecotoxicological information is not available. The chronic tests with *D. magna* (21 d) and early-life stage toxicity tests with *D. rerio* (33 d) were conducted as outlined in the OECD test guideline 211 and 210, respectively. In the 21 d *D. magna* chronic toxicity tests of cephradine, the number of young per female ( $\beta = -0.375$ ,  $p$  for trend = -0.004) and growth ( $\beta = -0.327$ ,  $p$  for trend = -0.013) were significantly decreased in a dose-dependent manner. The no observed effect concentrations (NOECs) based on the endpoints of survival, reproduction, and growth in *D. magna* exposed to cefadroxil and cephradine were 100 mg/L, except growth NOEC for cephradine (50 mg/L). In juvenile zebrafish exposed to cefadroxil for 33 d, the survival and growth endpoints were significantly affected at 10 mg/L. The effective concentrations of cefadroxil and cephradine were in a range between 10 and 100 mg/L, and therefore are several orders of magnitude greater than the levels potentially occurring in the ambient environment even including hotspots. *Acknowledgement* - This study was supported by the National Institute of Environmental Research in Korea.

#### MO057

##### **Toxicity of the antibiotic sulfamethoxazole to *Anabaena flos-aquae* and *Synechococcus leopoliensis*, a comparison of cyanobacteria species sensitivity.**

M. Baumann, Bavarian Environment Agency; K. Weiss; C. Polleleichtner, Ecotoxicological Laboratory; D. Maletzki; D. Schudoma, Federal Environment Agency

Sulfamethoxazole is a bacteriostatic sulfonamide antibiotic of large consumption amounts. Extensive research with well-established species like green algae, microcrustaceans and fish was done to uncover toxic effects of the antibiotic on aquatic organisms. Several studies confirm that the primary producers cyanobacteria (blue-green algae) are the most sensitive non-target organisms to antibiotics within the aquatic food web. The preferential test organism within the cyanobacteria group is *Anabaena flos-aquae*, but in some studies other species were used as well. In the present study a comparative investigation of the sensitivity of two cyanobacteria species, *A. flos-aquae* and *Synechococcus leopoliensis* to sulfamethoxazole was carried out. Ecotoxicological results of these bioassays indicate that toxicity on both species is comparable with each other. A risk assessment of sulfamethoxazole and a new freshwater quality standard is proposed by including these study results into the derivation process.

## MO058

### Effects of single veterinary and human pharmaceuticals and their mixtures on *Vibrio fischeri*

V. Di Nica,

In this study toxicity effects of ten human and veterinary pharmaceuticals (PhCs) were tested by using the bioluminescent bacterium *Vibrio fischeri* as non target organism (Microtox® test). Toxicity was measured for single chemicals, for different combinations of binary mixtures and for a multicomponent mixture of five veterinary PhCs (mixed at their equitoxic concentration ratio). From the concentration-response curves of single compounds it was possible to identify two different groups of PhCs. The compounds belonging to the same group showed comparable slopes leading to the hypothesis of a similar mode of action on *V. fischeri*. A comparison between the experimental EC50 with their respective baseline toxicity (calculated using QSAR models) indicates that most of the tested PhCs have a narcotic (polar and non polar) behavior; only the antibiotic chlortetracycline seems to have a specific mechanism of action on *V. fischeri*. The ratio between the experimental EC50 of single PhCs with measured environmental concentrations (MECs) in European water bodies gave an indication that these substances should not pose unacceptable risks for *V. fischeri*. On the other hand, the experimental toxicity data indicated a higher toxicity of binary mixture of PhCs, especially when the anti-inflammatory acetylsalicylic acid was present as a mixture component. Results from toxicity test for the multicomponent mixture in which PhCs were mixed in a ratio corresponding to their individual values of PNEC (Predicted No Effect Concentration) showed that the resulting EC10 value was at least two orders of magnitude above the sum of single-compounds safety threshold for aquatic organisms: the actual values of PNEC seem to be sufficiently conservatives also in mixture of chemicals.

## MO059

### Effects of pharmaceuticals on the immunocompetence of the great pond snail *Lymnaea stagnalis*

P. Boisseaux, P. Noury, Irstea Lyon; S. Betoulle, Université de Reims; J. Garric, Irstea Lyon

Wildlife is exposed to multistresses (e.g. chemicals and microbiologicals). The immune system has a pivotal role in the health of organisms, particularly to clear pathogens and parasites. Many xenobiotics exert immunotoxicological features. Among them, pharmaceuticals are biologically active pollutants that may especially interact with internal defences of non-target species. Hence, we aimed at assessing the short-term immunotoxic effects of diverse pharmaceuticals on *L. stagnalis* under controlled laboratory conditions. Molecules were chosen according to their abundance in surface waters (e.g. psychotropic drug, anti-cancer drug) and/or their mechanism of action (e.g. anti-inflammatory drug, immunosuppressive drug). Exposure concentrations scattered both, environmentally realistic and therapeutical-like concentrations. *Lymnaea stagnalis* has been chosen for several reasons. It is ecologically representative of lentic freshwater systems in Holarctic regions of the planet. It is proposed at the OECD for full lifecycle toxicity tests and for reprotoxicity tests. As an invertebrate, it possesses an open and innate-like immune system. Hence, the system is simplified and the hemolymph is in contact with all internal tissues. The circulatory cells are called hemocytes; they carry out many physiological functions (e.g. wound healing, transport of nutrients). Plus, they are immunocompetent (defence of intruders by many manners). The immunocompetence diagnosis was realized by measurement of diverse immune-related endpoints on each individual snail instead of a pooled approach. Flow cytometry was used to quantify hemocyte density, subpopulations, viability and phagocytosis activity. The NADPH-related oxidative activity was tracked by spectrofluorescence. This activity, called *oxidative burst* in vertebrate species, is both constitutive and inducible. For that reason it was activated by *ex vivo* addition of zymosan (a pathogen-molecular-pattern from yeasts) in order to see if they responded accordingly.

## MO060

### Evaluation of oxazepam impact on the *Radix balthica* transcriptome during embryonic development

J. MAZZITELLI, Centre Universitaire Jean-François Champollion, Albi, France / UMR CNRS

The aquatic organisms are frequently exposed to a wide diversity of chemical compounds suspended in water or absorbed on substrates. These compounds, such as pharmaceuticals, are often found in the environment *via* polluted effluents, whether they are domestic or industrial. Most pharmaceuticals, notably psychotropic pharmaceuticals, are very persistent in the environment even after biotic and abiotic treatment in waste water treatment plants (WWTP). The invertebrates represent 95% of the biodiversity. Among this biodiversity, the molluscs are broadly studied for their trophic level (*ie* primary consumer), but also because they have a relatively low mobility. Furthermore, all the different developmental stages of these organisms are of primary importance for the ecosystem. Among these freshwater molluscs, *Radix balthica* (Gastropoda, Pulmonata, Basommatophora) (Linnaeus 1758) fed on biofilm, protozoa, algae and organic substances. Water quality, temperature and food abundance have been shown to impact its life expectancy, but also its reproduction success. *Radix balthica*, hermaphrodite, breeds principally by outcrossing, but can become asexual in stress conditions. The aim of this study is firstly to evaluate the toxicity of four

psychotropic drugs from four different therapeutic classes and three chemical families. These compounds, broadly used and found in French WWTP effluents are oxazepam, carbamazepine, cyamemazine and sertraline. Only the oxazepam results will be presented here. Oxazepam toxicity is evaluated on *R. balthica* embryos (from the trochophore stage to hatching) *via* comparisons of hatching rate, hatching delay, shell defects and death rate between conditions. For oxazepam, these indicators showed toxicity from the environmental concentration (0.815 µg/L, minimum of the tested concentrations) to 100 µg/L, (maximum of the tested concentrations) including a pic of toxicity at 10 µg/L. Secondly, a differential RNAseq method has been used on *R. balthica* exposed to oxazepam at 10 µg/L and 0.815 µg/L or to artificial water for control. The organisms are sampled less than a day after hatching and ground for total RNA extraction and then sent to a sequencing platform. Statistical analyses have revealed 144 sequences differentially expressed for the 10 µg/L oxazepam condition and only 2 for the 0.815 µg/L concentration. These results obtained by a transcriptomic approach remain to be confirmed by RT-PCR.

## MO061

### Chronic toxicity of an antiepileptic on the clam *Venerupis philippinarum*

A. Almeida, Deapartamento de Biologia; R. Freitas, Biology; V. Calisto, CESAM Department of Biology; V. Esteves, CESAM Universidade de Aveiro; A.M. Soares, Universidade de Aveiro / Department of Biology and CESAM; E. Figueira, CESAM University of Aveiro

The presence of pharmaceutical drugs in the aquatic ecosystems is an emerging environmental problem. Among pharmaceutical drugs, Carbamazepine (CBZ), an antiepileptic, has been frequently detected in WWTPs influents and effluents, surface waters, groundwater and even in treated drinking water, with concentrations varying from 0.03 to 6.3 µg/L. The consumption of this drug and the low degradation rate upon WWTPs (< 10%) are the principal reasons for its occurrence in water bodies. Since CBZ is designed to exert a biological effect, when it reaches aquatic environment high probability exists for toxic effects on non-target organisms such as bivalves. The ecotoxicology of CBZ has been assessed, revealing the importance of chronic assays since they provide a more realistic approach. These studies reported that chronic tests display higher toxicity in comparison with acute exposures and that CBZ is responsible for changes in biomarkers related with an oxidative stress response. So, in the present work we aimed to study, through the use of a battery of physiological and biochemical biomarkers, how the clam species *Venerupis philippinarum* is affected by CBZ in a long-term exposure (28 d). The toxicity test was performed by exposing the clams to ecological concentrations of CBZ (0.00-9.00 µg/L). CBZ quantification based on a direct competitive ELISA, bioconcentration factor (BCF), clearance rate (CR), lipid peroxidation (LPO) levels, superoxide dismutase (SOD) and glutathione S-transferase (GST) activities were determined. Mortality was observed at the concentrations of 0.03 (5%), 0.30 (5%) and 3.00 µg/L (11%). At the control condition and 9.00 µg/L no mortality was registered. CR and BCF decreased at the highest CBZ concentration and the concentration of CBZ in clam tissues increased with the concentration of exposure. LPO levels, GST and SOD activities increased at CBZ 3.00 µg/L, with a decrease observed at the highest CBZ concentration to a “basal” level. Overall, after 28 d of exposure to CBZ, *V. philippinarum* showed an oxidative stress response. Nevertheless, the results obtained seem to show a mechanism of protection at the highest CBZ concentration, possibly due to the highest lysosomal trapping of CBZ and thus restriction of its toxic effects to this organelle. At lower concentrations no regulation in the entrapment of CBZ seems to occur, promoting higher toxic effects throughout the cell.

## MO062

### Effects of the pharmaceutical fluoxetine (Prozac®) in spiked-sediments on developmental and reproductive features of the polychaetes *Capitella teleta* and *Capitella sp A*

N. Mendez, ICMyL, UNAM / Unidad Academica Mazatlan; C. Barata, CSIC / Environmental Chemistry

The polychaete *Capitella capitata* constitutes a species-complex of several sibling species with different developmental strategies. It is a deposit-feeding organism which is widely used as an indicator of organic pollution and plays an important role in sewage waste cycling in marine and estuarine ecosystems. The antidepressant fluoxetine is excreted via human urine and can be accumulated in sediments close to sewage effluents and therefore it could pose a hazard to infauna inhabiting surrounding areas. The aim of this study was to assess effects of fluoxetine on juveniles and adults of two *Capitella* species through observations of their development and reproductive features. *Capitella teleta* was originally collected in organically polluted sediments from New York and was maintained in culture for more than 20 years. It is a hermaphroditic species with lecithotrophic development. *Capitella sp A* comes from a fish farm in Casas d'Alcanar (Tarragona) and is a dioecious species with lecithotrophic development. Sediments (< 60 mm) for the experiments were spiked with four fluoxetine concentrations (0.001, 0.03, 0.3 and 3.3 µg/g dry wt. sediment). Two experiments were performed with *C. teleta* to observe the effects of fluoxetine on juveniles (experiment 1: life table responses) and adults (experiment 2). Chronically exposed worms of *C. teleta* showed delay of maturity and delay or inhibition of copulation. Some males developed abnormal genital spines which can have adverse reproductive consequences during fecundation. Morphological abnormalities were observed in

two juveniles which could affect their feeding activity and growth. The third experiment performed with *Capitella* sp A juveniles and adults showed that fluoxetine enhanced proterogynous individuals that may be beneficial for the population. Worms of *Capitella* sp A only showed delay or inhibition of copulation. This is the first experimental study that assessed effects of fluoxetine spiked-sediments on development and reproduction of marine polychaetes. The observed fluoxetine adverse effects could have important ecological implications in natural populations due to the possible alteration or even inhibition of reproductive processes. Therefore, this study can contribute to understand the possible responses of benthic invertebrates after exposure to this pharmaceutical in natural environments.

#### MO063

##### **The Polychaete *Diopatra neapolitana* exposed to paracetamol: the use of the tissue regenerative capacity as a biomarker**

R. Freitas, Biology; D. Coelho, Universidade de Aveiro / Departamento de Biologia and CESAM; A. Pires, Universidade de Aveiro / Biologia; A.M. Soares, Universidade de Aveiro / Department of Biology and CESAM; E. Figueira, B. Nunes, CESAM University of Aveiro

Nowadays, there is an increasing concern about the large number of compounds present in the aquatic ecosystem, and the putative toxicological effects that may derive from their presence. Among these compounds one can find pharmaceutical drugs, which are continuously released into the wild by human activities. Although an increasing amount of data has been published on the occurrence of pharmaceuticals in the environment, a similar trend was not observed in terms of studies reporting and characterizing the potential deleterious effects of these compounds on non-target aquatic organisms, and information on their toxic effects in organisms other than human is still scarce. This is particularly true regarding the absence of data about physiological alterations undergone by polychaetes affected by this type of compounds. Essentially due to their life-history characteristics, as well as their relatively rapid response to pollution, several studies have been using polychaetes as sentinel species for anthropogenic (e.g. organic and inorganic contamination) and natural stresses (namely salinity alterations). Thus, in this study, the effects of the drug paracetamol were studied in the polychaete *Diopatra neapolitana*, using the tissue regenerative capacity as a biomarker. The results obtained revealed that individuals submitted to an induced lesion and exposed to the higher tested concentrations exhibited significantly lower capacity to regenerate their body, in comparison with control organisms or even animals exposed to environmentally (lower) relevant concentrations. This study evidenced that paracetamol can significantly induce physiological alterations in *D. neapolitana*, resulting in overall diminished tissue regenerative capacity, which is of extreme significance for a species with high ecological and economic relevance. Additionally, this study validates the use of *D. neapolitana* as a test organism in laboratory-based bioassays, but also as an adequate sentinel species to assess ecotoxicological effects of pharmaceutical drugs. **Keywords:** Polychaetes, body regeneration, biomarker, pharmaceutical drugs

#### MO064

##### **Antioxidant enzyme activities and lipid peroxidation in *Daphnia magna* exposed to an effluent spiked with pharmaceuticals and under single ozonation.**

A.O. Jiménez, Unidad de Toxicología Departamento de Sanidad Animal; S. Novais, Polytechnic Institute of Leiria and University of Aveiro / ESTM GIRM PIL and Department of Biology CESAM University of Aveiro; F. Beltrán, A. Espejo, University of Extremadura / Departamento de Ingeniería Química y Química Física; C. Gravato, University of Porto / Laboratory of Ecotoxicology; M. Lemos, Polytechnic Institute of Leiria and University of Aveiro / ESTM GIRM PIL and Department of Biology CESAM University of Aveiro

Application of Advanced oxidation processes used to remove pharmaceuticals from wastewater generates reactive oxygen species (ROS) that may reach superficial waters through discharges of effluents from sewage treatment plants. The main aim of this study was to clarify know if increased levels of ROS produced after application of a single ozonation treatment of a real effluent would induce changes in the antioxidant enzymatic activities superoxide dismutase and catalase, that protect tissues against superoxide anion ( $O_2^{\cdot-}$ ) and hydrogen peroxide ( $H_2O_2$ ) radicals respectively, and the level of oxidative damage (level of lipid peroxidation) in *D. magna*. Firstly, the wastewater was spiked with 9 selected pharmaceuticals (acetaminophen, antipyrine, caffeine, carbamazepine, diclofenac, hydrochlorothiazide, ketorolac, metoprolol and sulfamethoxazole at  $200 \mu g L^{-1}$  each) and then a single ozonation treatment was applied. Oxidative stress biomarkers were studied after an acute exposure period of 48 h to this treated effluent. The most marked change observed was an increase in the activity of SOD in daphnids that could be considered as a response to cope with increased levels of oxyradicals ( $O_2^{\cdot-}$ ) produced during the single ozonation treatment of the spiked effluent. **Acknowledgments:** Spanish CICYT, European Feder (Project CTQ2012/35789/C02/01), "Consejería de Empleo, Empresa e Innovación. Gobierno de Extremadura" and the Feder funds for the economic support.

#### MO065

##### **Interaction between an emergent contaminant and variations in abiotic conditions: the role of salinity in the modulation of the ecotoxicological**

##### **response of paracetamol**

B. Correia, CESAM University of Aveiro; R. Freitas, Biology; C.V. Silva; A.M. Soares, Universidade de Aveiro / Department of Biology and CESAM; E. Figueira, B. Nunes, CESAM University of Aveiro

A large body of evidence has emerged, showing the contamination of aquatic environments by pharmaceuticals, due to their common usage and release at wastewater treatment plants and, consequently, into aquatic ecosystems. The biological activity of pharmaceuticals is an important parameter to be considered when evaluating its toxicological impact on aquatic organisms, since many species have similar pharmacological targets to those of humans. Paracetamol has analgesic and antipyretic properties being one of the most used and detected drugs in aquatic environments, with several studies reporting its toxicity towards a significant number of aquatic organisms. The ecotoxicological responses elicited by anthropogenic chemicals can be influenced by a number of abiotic variables, including those that may vary due to global changes. Among these, and with particular emphasis in estuarine environments, one can find salinity. In order to characterize the toxic response caused by paracetamol, the present work assessed the levels of the antioxidant defence system of the clam *Venerupis philippinarum*, including the activities of GSTs isoenzymes, catalase, superoxide dismutase, and glutathione reductase; oxidative damage (lipoperoxidation); antioxidant balance (GSH/GSSG), under different salinity conditions. Animals were collected from the wild (Ria de Aveiro lagoon, Portugal), and acutely (96h) exposed to ecologically relevant paracetamol levels (0.05; 0.5; 5mg/l), under three distinct salinity values (14, 28 and 35 psu) simulating extreme and actual conditions already reported in the area of collection. The results demonstrated an oxidative effect, significant for the tested parameters. The biological response towards exposure to paracetamol was particularly evident in terms of superoxide dismutase (SOD) activity, with significant increases for some of the paracetamol treatments. Furthermore, significant increases were also observed for the biomarkers catalase and glutathione reductase, but only for one salinity level. The ratio of reduced and oxidized glutathione (GSH/GSSG) was dramatically affected by paracetamol, with opposite effects under salinities of 14 and 28 psu. It is possible to conclude that water salinity strongly influenced the response of the clams to different paracetamol concentrations, showing the importance of studying physiological traits under realistic test conditions, which are likely to vary in great extent as a result of climate change.

##### **Effects of ibuprofen and carbamazepine on Na<sup>+</sup>/K<sup>+</sup>-ATPase system in *Solea senegalensis* acclimated at two temperatures**

A. González-Mira, Universitat de Valencia / Departamento Biología Funcional y Antropología Física; F. Hontoria, IATS-CSIC / Instituto de Acuicultura de Torre de la Sal Dpt Biología Cultivo y Patología de especies Marinas; A. Torrealba, University of Valencia / Department of Animal Biology; M. Solé, Consejo; I. Varo, Spanish Research Council (CSIC) / Biology culture and pathology of marine species

The first responses that occur when an animal face changes in environmental conditions are alterations at the molecular level. These responses typically include changes in gene expression and protein abundance that may lead to changes in enzyme activities. Pharmaceuticals can reach all kind of water bodies, including those of estuarine and marine coastal areas. Seasonal and climate driven temperature variations may affect fish physiology at different biological levels. *Solea senegalensis* (Senegalese sole) is a marine teleost that inhabits coastal and estuarine waters. In order to determine how temperature of acclimation can modulate the effect of some pharmaceuticals on the osmoregulation mechanisms in sole Na<sup>+</sup>/K<sup>+</sup>-ATPase alpha 1a1a and 1a1b subunits gene expression and Na<sup>+</sup>/K<sup>+</sup>-ATPase enzymatic activities were determined in different osmoregulatory tissues. Sole juveniles were acclimatized in four replicate tanks at two different temperatures, 15°C and 20°C, for a period of 60 days. After that period, they were administered an intraperitoneal injection (IP) of the non-steroidal anti-inflammatory drug (NSAID) ibuprofen (IB; 10 mg/Kg) and the anti-convulsing drug carbamazepine (CBZ; 1 mg/Kg). Non-injected fish, and those injected with the carrier (sunflower oil), acclimated at each of the two temperatures, were used for comparison. Ibuprofen showed an effect on the osmoregulatory mechanisms through alterations in the gill Na<sup>+</sup>/K<sup>+</sup>-ATPase activity. In addition, the number of copies on both Na<sup>+</sup>/K<sup>+</sup>-ATPase alpha 1a1a and 1a1b subunits was higher at 20°C than at 15°C, which could be a direct response to temperature. This work was financed by the Ministry of Science and Innovation of Spain (Ref 458 CTM2010-16611) and by PROMETEO II/2014/085 (GV).

#### MO067

##### **The effect of dexamethasone on the hepatic CYP450 system of rainbow trout (*Oncorhynchus mykiss*)**

V. Burkina, University of South Bohemia in Ceske Budejovice / Faculty of Fisheries and Protection of Waters South Bohemian Research Center of Aquaculture and Biodiversity of Hydrocenoses Vodnany Czech Republic; S. Sakalli, Faculty of Fisheries and Protection of Waters; O. Koba, University of South Bohemia in Ceske Budejovice / Faculty of Fisheries and Protection of Waters; G. Zamaratskaia, Swedish University of Agricultural Sciences / Department of Food Science; G.T. Pham, University of South Bohemia in Ceske Budejovice / Faculty of Fisheries and Protection of Waters; R. Grabic, University of

South Bohemia in CB / Faculty of Fisheries and Protection of Waters, South Bohemian Research Center of Aquaculture and Biodiversity of Hydrocenoses; T. Randak, University of South Bohemia in Ceske Budejovice Faculty of Fisheries and Protection of Waters / Laboratory of Environmental Chemistry and Biochemistry; V. Zlabek, University of South Bohemia in Ceske Budejovice / Faculty of Fisheries and Protection of Waters LECHB

The present study aimed to assess sub-lethal effects of dexamethasone (DEX) on juvenile rainbow trout. DEX, a potent synthetic glucocorticoid, have been detected in waste and surface waters in concentrations from 0.001 to 23 µg/L. These concentrations might have negative impacts on fish health. We investigated *in vivo* effect of DEX on cytochrome P450 (CYP450) system in hepatic fish microsomes. Fish were exposed at concentrations of 3, 30, 300 and 3000 ng/l over a period of 21 days. Total CYP450 content and activity of the following enzymes were measured: 7-ethoxyresorufin O-deethylase (EROD), p-nitrophenol hydroxylase (PNPH), 7-benzoyloxy-4-trifluoromethylcoumarin O-debenzylase (BFCOD) and 7-benzoyloxyquinoline O-debenzylase (BQOD). The total CYP450 content was lower in the groups exposed to 3, 30 and 300 ng/l of DEX after 21 days of exposure. The significant inductions were observed in all CYP450s activities. Differences in the directions of the response to DEX in total CYP450 (decrease) and CYP450 activities (increase) confirm that variations in CYP450 activity cannot be explained by variation in total CYP450 content. Usually, CYP450 activities induce due to *de novo* RNA and protein synthesis. In this study, simultaneous decrease in total CYP450 and increase in the activities of individual CYP450s suggest other mechanism of induction, for example, inhibition of the protein degradation. Further studies are needed to elucidate the exact mechanism of CYP450 activity induction by DEX. The other explanation might be a dramatic decrease in the protein content of these CYP450s, which were not measured in this study. Thus, the eventual increase in the measured CYP450s remained invisible and did not lead to increase in total CYP450 content. This hypothesis can be tested by determination of protein content of individual CYP450 isoforms. DEX at the concentration 3000 ng/l did not alter any of investigated parameters suggesting biphasic regulation of CYP450 by DEX. In conclusion, DEX at the concentrations of 3, 30 and 300 ng/l can modify both total CYP450 content and CYP450 activity in rainbow trout. **Keywords:** Dexamethasone; CYP1A; CYP2E1-like protein; CYP3A. *Acknowledgement* - The study was supported by the MEYS of the CR - projects „CENAKVA“ (No.CZ.1.05/2.1.00/01.0024) and „CENAKVA II“ (No.LO1205 under the NPU I program), by the Grant Agency of the USB GAJU (No.087/2013/Z) and by the Czech Science Foundation (No.P503/11/1130).

#### MO068

##### **Reversibility of reproductive efficiency in zebrafish exposed to 17β-estradiol (E2) and 17α-ethinylestradiol (EE2) after treatment with powered activated carbon (PAC)**

J. Silva, Sao Paulo State University - UNESP / Eng Ambiental; G.D. Alkimin, São Paulo State University - Campus of Sorocaba; S. Nakahira, Universidade Estadual Paulista - UNESP; S. Daccach; C.E. Correa, São Paulo State University - Campus of Sorocaba; R. Fracacio, Unesp

Endocrine disruptors, as the estrogens, have been found in wastewater, even after treatment, and they are known to affect the reproduction of local biotas, indicating the necessity of effective treatments. Therefore, powered activated carbon (PAC) is a promising alternative for water treatment. The purpose of this study was evaluating the chronic toxicity of 17β-estradiol (E2) and 17α-ethinylestradiol (EE2) in zebrafish on reproductive phase, and to investigate the capacity of biological recuperation of these organisms after water treatment with PAC. 69 replicates with two test-organisms each, were exposed to chronic test. Among them, 23 replicates were submitted to 30 ng.L<sup>-1</sup> test-solution for each hormone (E2 and EE2 group) during 21 days. The other replicates remained free of contamination and served as control group in this study. At the end of chronic period within each experimental group : I) seven female fish were sacrificed for analyzing the gonads; II) 6 male and 3 female fish were transferred to breeding tanks maintaining a ratio of 2 males for one female; III) other 23 fishes remained alive for the recovery test with a test-solution treated with PAC until the 28<sup>th</sup> day of the experiment. Afterwards, the steps I and II were repeated. Kruskal-Wallis tests detect significant differences (p< 0.05) in the gonadosomatic index (GI) between the control and E2 group compared to EE2 group, before and after treatment with CAP. The number of eggs per female obtained by EE2 group also was significantly lower compared to the other groups, not producing eggs even after recovery period. Nevertheless, there was a significant recuperation of hatching rate, from 22,85% for hatched eggs after E2 exposition, to 68,21% after PAC treatment. Regarding to the viability of the larvae, 100% of the hatched embryos survived until the 7<sup>th</sup> day of life in the control group; 98,61% in the group exposed to E2, and 97,59% after PAC treatment. This study concludes that the zebrafish is a model to demonstrate endocrine disruption effects on reproductive function. The negative influence of synthetic hormone EE2 on the health and development of female gonads was demonstrated by the results of GI and number of eggs presented. However, the treatment with CAP reversed the reproductive capacity of zebrafish after chronic exposure to E2.

#### MO069

**Effects of the pharmaceutical gemfibrozil on gilthead seabream *Sparus aurata***  
A. Barreto; L.G. Luis, CESAM & Department of Biology / Department of Biology; A.M. Soares, Universidade de Aveiro / Department of Biology and CESAM; K.

Hylland, University of Oslo / Biosciences; S. Loureiro, Universidade de Aveiro / Biology; M. Oliveira, Laboratory of Ecotoxicology and Ecology  
The presence of human pharmaceuticals in the aquatic environment is raising concern on their effects to the environment and human health. Blood lipid lowering agents are among the most commonly found drugs in the aquatic environment. Gemfibrozil, one of the most frequently detected pharmaceuticals from this class, may be considered a high priority pharmaceutical on the basis of its consumption, physico-chemical properties, environmental occurrence and persistence. However, the study of its environmental fate and effects is quite scarce. This study was designed to evaluate the effects of this pharmaceutical to an estuarine/marine fish, the gilthead seabream (*Sparus aurata*), after a 96-hour exposure. To that end behavioral and biochemical responses were assessed as endpoints. The consequences of short-term exposure of gilthead seabream to environmentally relevant concentrations of gemfibrozil was evaluated and the most sensitive biomarkers identified. **Keywords:** Toxicity, Biomarkers, Gemfibrozil, *Sparus aurata*. **Acknowledgments:** This research was supported through the COMPETE " \_ Operational Competitiveness Programme and national funds through FCT – Foundation for Science and Technology, under the project “NANOAu - Effects of Gold Nanoparticles to Aquatic Organisms” (FCT PTDC/MAR-EST/3399/2012) (FCOMP-01-0124-FEDER-029435), “Pest-C/MAR/LA0017/2013” and “Pest-C/CTM/LA0011/2013”; A. #### MO070

##### **Neurotoxic potential evaluated in *Corbicula fluminea* exposed to human pharmaceuticals**

G.V. Aguirre-Martinez, Universidad de Cadiz / Chemical Physical; C. Andre, Environment Canada; F. Gagne, Emerging Methods, Environment Canada / Emerging Methods; A. DelValls, University of Cadiz / Departamento de Química Física Facultad de Ciencias del Mar y Ambientales; L. Martin-Diaz, University of Cadiz / Facultad de Ciencias del Mar y Ambientales

Adverse effects of pharmaceuticals on aquatic life have been demonstrated. However, for most drugs they are not well understood. This research aimed to evaluate neurotoxic potential on *Corbicula fluminea* after exposure to carbamazepine, novobiocin and tamoxifen. During 28 days water was spiked every 24 hours with selected drugs (0; 0.1; 1; 10; 50 µg/L). Pharmaceuticals stocks were prepared in DMSO (0.001% v/v). Biomarkers studied in gonad tissues included Dopamine (DOP), Arachidonic Acid Cyclooxygenase activity (COX), Monoamine Oxidase activity (MAO), Mitochondrial Electron Transport (MET), Total Lipids (TLP), Vitellogenin (VTG), and Energy Consumption (MET/TLP). Results showed a concentration-dependent relationship on DOP levels, MAO and TLP after exposure to drugs (p< 0.05). Neurotoxic effects included significant increase (p< 0.05) in DOP levels of clams exposed to carbamazepine and novobiocin, and to tamoxifen at 10 and 50 µg/L. The turnover of DOP was accompanied by increased catabolism, as evidenced by a significant increased MAO activity compared with controls (p< 0.05). MAO activity increased in clams exposed to novobiocin and tamoxifen at environmental concentrations, and to carbamazepine (10 and 50 µg/L). Drugs also induced significantly MET and COX activity compared with controls (p< 0.05). TLP increased significantly respect to controls in clams exposed to environmental concentrations of drugs (p< 0.01). Energy consumption did not differ with controls except for clams exposed to carbamazepine (1 µg/L). VTG decreased when increasing concentrations. Environmental concentrations of selected drugs have the potential to induce neurotoxicity. Selected biomarkers are suitable for environmental risk assessment of selected drugs in aquatic environment using *C. fluminea* as bioindicator species.

#### MO071

##### **Responses of antioxidant defense system in liver and gill of rainbow trout (*Oncorhynchus mykiss*) chronically treated with dexamethasone**

V. Zlabek, University of South Bohemia in Ceske Budejovice / Faculty of Fisheries and Protection of Waters LECHB; V. Burkina, University of South Bohemia in Ceske Budejovice / Faculty of Fisheries and Protection of Waters South Bohemian Research Center of Aquaculture and Biodiversity of Hydrocenoses Vodnany Czech Republic; S. Koba, University of South Bohemia in Ceske Budejovice / Faculty of Fisheries and Protection of Waters; G. Thai, University of South Bohemia in Ceske Budejovice / Faculty of Fisheries and Protection of Waters South Bohemian Research Center of Aquaculture and Biodiversity of Hydrocenoses Vodnany Czech Republic; R. Grabic, University of South Bohemia in CB / Faculty of Fisheries and Protection of Waters, South Bohemian Research Center of Aquaculture and Biodiversity of Hydrocenoses; T. Randak, University of South Bohemia in Ceske Budejovice Faculty of Fisheries and Protection of Waters / Laboratory of Environmental Chemistry and Biochemistry

Measuring of antioxidants enzyme activities and damage from reactive oxygen species (ROS) become a useful tool in determination of harmful effects of organic pollution in aquatic toxicology. Dexamethasone (DEX) is a potent synthetic member of the glucocorticoid class of steroid drug and has been found in effluents of sewage treatment plants at concentrations of 3-30 ng/L. In present study, the sublethal effects of DEX in juvenile rainbow trout were investigated, the response of antioxidant enzymes (superoxide dismutase, SOD; catalase, CAT; glutathione peroxidase and reductase, GPx and GR) and level of thiobarbituric acid reactive species were determined in liver and gill tissues after 21 and 42 days. This study showed that antioxidant defense system in fish was affected by DEX including environmentally relevant concentration after 21 days of exposure. The significant responses of fish to DEX exposure in SOD, CAT, and GPx activities displayed various dependent patterns. SOD was significantly induced by two highest DEX concentrations in gill after 21 days. CAT activity was affected by environmentally relevant concentration of DEX in liver and gill after 21 days. GPx activity in liver of fish exposed to 300 and 3000 ng/L for 21 days was significantly higher compared with control, while the activity of GPx was significantly lower in all DEX exposed groups after 42 days of exposure. Such result might suggest adaptive response of organism to ROS production during experimental period. Finally, lipid peroxidation level (measured as TBARS) was significantly induced by two highest DEX concentrations in liver after 42 days. The reason of oxidative stress could partly be due to detoxification process by cytochrome P450 system, which is potential source of ROS production (Burkina et al., 2014; poster at SETAC). In conclusions, results of the present study declare a potential harmful impact of residual DEX in aquatic environment on non-target species like fish.

**Acknowledgement** - The study was financially supported by the MEYS of the CR - projects „CENAKVA“ (No. CZ.1.05/2.1.00/01.0024) and “CENAKVA II“ (No. LO1205 under the NPU I program), by the Grant Agency of USB GAJU 087/2013/Z and the Grant Agency of Czech Republic P503/11/1130.

## MO072

### **Morphine disrupts innate immune system in zebrafish embryos: immunosuppressive effects and involvement of ABC transporters in lipopolysaccharide-induced inflammation**

H. Mottaz, Eawag / UTOX; R. Schoenenberger, Eawag, Aquatic Research / UTOX; S. Fischer, Eawag, Swiss Federal Institute of Aquatic Science and Technology / Environmental Toxicology; R.I. Eggen, Eawag / Department of Environmental Toxicology; K. Schirmer, Eawag / Environmental Toxicology; K.J. Groh, Eawag / UTOX Environmental Toxicology

Opioid drugs, such as morphine (MO), detected in waste and surface waters worldwide, may harm fish due to their semi-persistence and potency. Here, we studied MO effects on the innate immune system in zebrafish embryo. Bacterial lipopolysaccharide (LPS) challenge assay was established, where waterborne LPS is added to promote inflammation and subsequent mortality, and time course of survival is monitored. Embryos were exposed to MO (concentrations confirmed by LC-MS/MS) from birth until LPS assay at 4 days post fertilization. Responses to LPS were bell-shaped, in that 100 ng/L-100 µg/L MO-exposed embryos exhibited significantly lower survival, while 1 mg/L exposed group did not differ from control (unexposed). RT-PCR analyses showed that MO above 10 µg/L caused progressive downregulation of various genes involved in inflammation, including MYD88, TRIF, TRAF6, p53, p38, NFκβ2, IL1β, IL6, IL8, CC-Chemokine and iNOS. Fish exposed to 1 mg/L accumulated 9.5 ng/g of MO after 4 days of exposure, a concentration comparable to that reported in blood of chronic drug users subject to higher infection rates. This confirms the expected immunosuppressive effects of MO. The immunosuppression at higher MO concentrations apparently counteracts another influence that leads to increased inflammation at lower MO concentrations. Such exacerbation of LPS-induced inflammation, occasionally reported in mammals as well, is considered a paradoxical effect with an unknown mechanism. As we have observed that MO downregulated ABCB4 and ABCC2 gene expression already at 100 ng/L, we investigated whether ABC transporters play a role. One hour pre-exposure (before LPS addition) to 5 µM cyclosporine A, a known inhibitor of ABCC and ABCB transporter activity, led to increased inflammation. At lower CsA concentrations, progressively smaller differences to control fish survival were observed, correlating with lower uptake of fluorescent dye that reflects lower degree of ABC pump inhibition. Ongoing experiments aim to precisely characterize the quantitative relationship between ABC transporter inhibition and response to LPS. This work provides an indication for a novel role of ABC transporters in bacterial pathogen-host interaction. As the inhibition of ABC transporters by otherwise benign compounds has been reported in aquatic organisms, this discovery points to potential adverse effects on immune system of fish caused by chemical interference with ABC transporter expression or activity.

## MO073

### **Ecotoxicological evaluation of sedative-hypnotics drugs using zebrafish embryos as model organisms**

J.T. Souza, University of Brasilia / Departamento de Genética e Morfologia Instituto de Biologia; C. Lisboa, University of Brasilia - Gtox / Department of Genetics and Morphology; I.B. Ferraz, Universidade de Brasília - Gtox / Departamento de Genética e Morfologia Instituto de Biologia; D.S. Moura, Universidade de Brasília / Genética e Morfologia; R. Oliveira, University of

Brasilia / Department of Genetics and Morphology; C.K. Grisolia, University of Brasilia / Department Genetics and Morphology  
Zolpidem hemitartrate (Zol) and Bromazepam (Bro) are sedatives and hypnotics drugs that act on the central nervous system (CNS) decreasing its activity. Both, Zol and Bro are used to induce sleep-sedation and to treat anxiety. In spite of similar applications, Zol and Bro have different mode of action. Zol belongs to imidazopyridine class being a selective agonist of GABA<sub>A</sub> receptors the major inhibitory neurotransmitter in CNS. On the other hand, Bro belongs to the class of benzodiazepines drugs, the most significant class of sedative-hypnotics being widely used in clinics. The aim of this study was to evaluate the toxic effects of two formulations of psychiatric drugs commonly used in Brazil, Zol formulation known as Noctiden (Biolab) and a Generic formulation of Bro (Biosinteca). To do so, *Danio rerio* embryos were chosen as model organisms for ecotoxicological evaluation. All Tests performed are based on an extended version of the OECD protocol No. 236 - Fish Embryo Toxicity (FET) test. For each drug were prepared seven concentrations: 0, 1.0; 1.9; 3.7; 7.2; 13.9; 26.8; 51.8 mg/L for Zol; and 0, 0.4; 1.1; 3.5; 11.1; 35; 110.7; 350 mg/L for Bro. A total of sixteen organisms per concentration were divided in three 24-well microplates and exposed to 2 ml of test solutions. Developmental abnormalities, hatching, behaviour and mortality were assessed during 7 days. The 4d - LC<sub>50</sub> for Zol and Bro were 38.2 and 59.2 mg/L, respectively. With the extension of the test time dependent toxicity trend was observed for both compounds especially for Zol (7d - LC<sub>50</sub> = 17.1 mg/L). Effects on behaviour (loss of equilibrium, erratic swimming and paralysis) were observed for Zol in concentrations from 3.7 mg/L and for Bro in concentrations ten times higher from 35 mg/L. Moreover several malformations were induced including lack of pigmentation (eye and body), oedemas, and tail deformities. For behavioural and embryotoxicological analysis the extension of the test was essential to an accurate assessment of both drugs. Altogether, the effects induced by both drugs might indicate severe effects of these drugs in a chronic scenario of exposure. Little is known about the psychiatric drug in the environment. Additional tests designed considering the mode of action of sedative-hypnotic drugs such neurological biomarkers (CNS gene expression), refined behaviour analysis and feeding test (food capture and prey avoidance) are recommended.

## MO074

### **Effects of Gemfibrosil in Zebrafish embryo survival and larvae locomotory activity**

J. Henriques, Universidade de Aveiro / Department of Biology; A.R. Almeida, University of Aveiro / Biology; A.M. Soares, Universidade de Aveiro / Department of Biology and CESAM; I. Domingues, University of Aveiro / CESAM Department of Biology; M. Oliveira, Laboratory of Ecotoxicology and Ecology  
Pharmaceutical products are worldwide emerging contaminants due to a consequent increased consumption by human and veterinary medicine. Thus, this contaminants and their metabolite are altogether released in sewage waters, mainly through excreta. It has been reported that the elimination of some of this pharmaceutical compounds during wastewater treatment processes has been rather inefficient, and as a result, they are found in surface, ground and drinking waters. Fibrates such as Gemfibrozil are used in human medicine to reduce blood concentrations of cholesterol and triacylglycerols. These class of pharmaceuticals are some of the most frequently reported in wastewaters and surface waters. Although most of these compounds have reduced and limited half-lives, they may present the same exposure potential as persistent pollutants as these have a continuous input into the environment. Moreover, some studies have already demonstrated the negative impact in physiological and/or reproductive endpoints in adult fish, however, survival and behavioural effects in fish larvae are lacking. In our work, we aimed to study the effects of Gemfibrosil in zebrafish embryo survival and larvae locomotory activity. Zebrafish embryos were exposed to both lethal and sub-lethal concentrations of the fibrate Gemfibrozil and lethality and sub-lethal endpoints were recorded daily for 96h. Sub-lethal concentrations where no apparent malformations occurred were used to test for behaviour analysis of 120-144 hpf larvae using a Zebrafish (Viewpoint®). Preliminary data shows that even in concentrations where no lethality occurred there seems to be an effect in fish locomotor behaviour.

## MO075

### **Effects of the beta-blocker metoprolol and the NSAID diclofenac on the embryonic development and health of brown trout *Salmo trutta* f. fario**

S. Schwarz, Animal Physiological Ecology; H. Schmiel, Tübingen University / Animal Physiological Ecology; M. Scheurer, Water Technology Center TZW Karlsruhe; F. Sacher, DVGW-Technologiezentrum Wasser; H. Köhler, University of Tübingen / Animal Physiological Ecology; R. Triebkorn, University of Tübingen / Animal Physiological Ecology

The discharge of human and veterinary pharmaceuticals into surface waters via wastewater treatment plants is an increasing problem in central European countries, especially with respect to demographic changes. However, despite the frequent detection of various substances in aquatic ecosystems, knowledge on their effects in biota is still scarce. Available data are based on standard biotests with model test organisms which lack ecological relevance. Among the pharmaceuticals most frequently used and, hence, also frequently detected in surface waters, the beta-blocker metoprolol and the non-steroidal anti-inflammatory drug diclofenac are of particular interest and importance. While various studies concerning

diclofenac already exist, the ecotoxicological potential of environmentally relevant concentrations is still discussed. In the case of metoprolol only very few effect studies are available. Our study investigated the effects of the two substances on the health status and on the embryonic development of brown trout, *Salmo trutta f. fario*, a species of high local ecological relevance for central Europe. The applied concentrations were 0.1, 0.5, 1, 10, and 100 µg/L for diclofenac, and 0.1, 1, 10, 100, and 1000 µg/L for metoprolol, thus including several concentrations in ranges that have been reported for German surface waters. Juvenile fish were exposed for a time period of 27 days. Besides biometric measurements and mortality, the level of the stress protein Hsp70 was measured as a general marker of proteotoxicity. Furthermore, the degree of lipid peroxidation, which is supposed to be reduced by NSAIDs, and the histological status of liver, kidney, gill, and heart (only for metoprolol) as a measure of overall health condition were investigated. The exposure of trout eggs/embryos was based on OECD 212. Recorded endpoints included mortality, time till eye development, time to hatch, number of hatched larvae, and number of healthy larvae at the end of the test. Overall, our study aims at providing further information on the effects of environmentally relevant concentrations of two frequently used pharmaceuticals in a species of high ecological relevance in Germany and adjacent countries.

## MO076

### The ecotoxicological effects of 4 common human anti-inflammatory agents on the unicellular green algae *Chlamydomonas reinhardtii*

M. Pino, San Jorge University / Facultad ciencias de la salud; S. Muniz, D. Chinarro, San Jorge University; E. Navarro, CSIC - Spanish National Research Council / Biodiversity conservation & Ecosystems Restoration  
Pharmaceutical compounds such as non-steroidal anti-inflammatory drugs (NSAIDs) and antibiotics are used extensively worldwide and their consumption, predominantly in developed countries, is assumed to be higher than several hundred tons per year (Daughton and Ternes, 1999). Approximately 70% of administered drugs are estimated to be released into the environment (Jacobsen and Berglund, 1988), mainly as complex mixtures via both untreated and treated sewage (Ternes et al., 2004; Yu et al., 2011). That would explain the increasing evidence of pharmaceutical ubiquity in the environment. Although the global impact of pharmaceuticals in ecosystems still remains unclear, *in vitro* and *in vivo* assays have demonstrated their ecotoxicity effects on many non-target organisms. Thus, the aim of this study was to measure the acute ecotoxicity of four NSAIDs with a widespread presence in the environment (ibuprofen, diclofenac, paracetamol and salicylic acid) by using for the first time the algae *Chlamydomonas reinhardtii* as aquatic model organism. Our results indicate that all of the studied drugs are likely to cause toxic effects on the photosynthetic yield of *Chlamydomonas reinhardtii* (EC<sub>50</sub> in the range of 660 to 2286 mg/L). The salicylic acid was the most toxic followed by ibuprofen, diclofenac and paracetamol. However, and based on the concentrations found in natural waters, the four NSAIDs are not expected to represent an acute risk, for this aquatic biota.

## MO077

### Anthropogenic gadolinium: environmental concentrations in Lorraine region (France) and effects on living organisms

E. Perrat; M. Parant, Université de Lorraine; C. ROSIN, ANSES / Member of the Working Group; C. Cossu-Leguille, Laboratory LIEBE - CNRS UMR 7146 - Université de Lorraine  
Gadolinium-based contrast agents (Gd-CA) are often used in Magnetic Resonance Imaging (MRI). After blood injection (from 160 to 240 mg/L), these compounds are released by urinary excretion for several weeks (Kummerer et al., 2002). Then, due to the lack of specific recycling process in European Waste Water Treatment Plants (WWTPs), these pharmaceuticals are released in the aquatic environment and found in river and tap water (Bau & Dulski, 1996). During our study, we decided to measure Gd concentrations in the aquatic environment of Lorraine region (France) and to evaluate toxicity of the most currently used Gd-CA (Dotarem®) in realistic concentrations of exposure according to our environmental measurements. Water was sampled on 23 sites in Lorraine (France). After ICP-MS analysis, total Gd concentrations were measured and anthropogenic Gd concentrations ranged from 20 ng/L to 10 µg/L. Impacts of Dotarem® were studied with ecotoxicity and bioaccumulation assays. These approaches were developed on two species of green unicellular algae (*Chlorella vulgaris* and *Pseudokirchneriella subcapitata*) and on daphnids (*Daphnia magna*). Both algae were exposed during 6 days to Gd by using variable Gd-CA spiked media. *Daphnia magna* were exposed during 50 days to Gd by using variable Gd-CA concentrations via different ways: media contaminated, spiked food (i.e. algae contaminated with Gd-CA), and both. Gd-CA concentrations were chosen in accordance to previously measured environmental Gd concentrations (i.e. 0, 20, 200, 600, 1 000, 5 000, 10 000 ng/L). Morphological responses, growth and Gd concentrations were followed on algae and daphnids, in addition offsprings number was counted for daphnids. The most important effect was observed on daphnids in the presence of contaminated food. In this case, mortality appeared 1 week earlier than compared to media contaminated. No significant bioaccumulation was observed neither in daphnids nor in algae, probably due to the chemical form of gadolinium in Dotarem®. This study focussed on Gd-CA ecotoxicity after aquatic environmental release. According to our observations, freshwater organisms are impacted by this type of contamination, while formulation of Gd-CA are known to induce a high-limited toxicity for

humans when used for MRI (Amet & Deray, 2012; Galera et al., 2010). **Keywords** : Bioaccumulation; Ecotoxicity; Gadolinium-based contrast agents; Aquatic freshwater organisms

## MO078

### Bioconcentration of tamoxifen in aquatic organisms (microalgae, daphnids and fishes)

F. ORIAS, ENTPE-LEHNA-IPE / ENTPELEHNAIPE; L. SIMON, Université de Lyon / Lyon LEHNAES; Y. PERRODIN, Université de Lyon / ENTPELEHNAIPE  
Pharmaceutical compounds (PCs) are ubiquitous in aquatic ecosystems all over the world. This kind of molecules shows an ecotoxicological risk not only because of their direct ecotoxicity but also because of their potential of accumulation in exposed organisms (bioconcentration). Among bioaccumulative PCs, some of them have already been detected in environment, and notably the tamoxifen. In order to assess the potential of bioconcentration of tamoxifen in aquatic organisms, we exposed 3 species, belonging to three different trophic levels (*Pseudokirchneriella subcapitata* (primary producer), *Daphnia magna* (primary consumer) and *Danio rerio* (secondary consumer), to concentrations of tamoxifen from 0.1 µg/L to 100 µg/L during several days. For follow the tamoxifen content inside tested organisms, we used an innovative method based on the measurement of δ<sup>14</sup>N/<sup>15</sup>N. This is why we used <sup>15</sup>N tamoxifen in our experiments. Our results shows that tamoxifen is strongly bioaccumulative in all tested organisms with bioconcentration factors from 8000 (fish liver) to 27000 (algae). We found that the higher in the trophic web is the organism, the lesser is the bioconcentration factor. These results confirm that there is an ecotoxicological risk, beyond the direct ecotoxicity, for organisms exposed to tamoxifen in aquatic ecosystems.

## MO079

### Bioaccumulation and trophodynamics of sertraline and fluoxetine in laboratory three-level aquatic food chains

O. Berglund, Lund University / Dept of Biology; M. Bostrom, Lund University / Biology; J. Jönsson, Lund University / Center for Analysis and Synthesis  
To test the influence of food on bioaccumulation of pharmaceuticals we exposed two three-level aquatic food chains to the selective serotonin reuptake inhibitors (SSRIs) sertraline and fluoxetine in a laboratory set-up. The constructed food chains shared the two lower trophic levels (detrital maple leaves, *Acer platanoides* fed on by the detritivorous isopod *Asellus aquaticus*), but differed in the secondary consumers (the water beetle *Notonecta glauca*, and the nine-spined stickleback *Pungitius pungitius*, both feeding on *A. aquaticus*). Neither of the SSRIs biomagnified in the food chain, concentrations showed a decreasing trend from detritus to isopods to predators. Bioaccumulation factors (BAFs) calculated as concentration in organism divided with concentration in water were for sertraline: 2200±1300 for detritus, 360±230 for isopods, 26±10 for *N. glauca* and 49±37 for *P. pungitius*, all on a wet weight basis. The corresponding BAFs for fluoxetine were: 1300±600, 110±50, 11±4, and 41±34. BAFs for the organisms feeding on contaminated food were not different to bioconcentration factors (BCFs) measured in a separate experiment with water exposure only. Thus, food or trophic transfer did not have a major influence on the accumulation of the SSRIs in this study.

## MO080

### The uptake and elimination of selected pharmaceuticals in the aquatic invertebrate, *Gammarus pulex*

T.H. Miller, Kings College London / Analytical and Environmental Sciences; R.J. Brown, wca consulting; S.F. Owen, AstraZeneca / Safety Health Environment; N.R. Bury, Kings College London / Division of Diabetes and Nutritional Sciences; L. Barron, Kings College London / Analytical and Environmental Science  
Through the contamination of surface water, aquatic biota are exposed to a varying number of contaminants such as the class of pharmaceutical and personal care products (PPCPs). Sources of contamination are a result of anthropogenic activities (agriculture, landfill sites, health and veterinary services). The exposure of these organisms to pharmaceuticals has been shown to have varying toxic effects in reproduction and also affect behaviour<sup>1</sup>, yet data on their toxicokinetics are lacking. Therefore, the understanding uptake and elimination of pharmaceuticals in aquatic life is essential to identifying compounds that may pose significant risk through the accumulation via water or diet<sup>2</sup>. Herein, we present a method for the determination of toxicokinetics of several pharmaceuticals in the aquatic invertebrate, *Gammarus pulex*. Field-collected Gammarids were acclimatised in the laboratory for use in the exposure experiments. *G. pulex* were exposed individually to environmentally relevant concentrations of eight radiolabelled pharmaceuticals (<sup>14</sup>C or <sup>3</sup>H) including propranolol, diclofenac, metoprolol, ibuprofen, imipramine, terbutaline, ranitidine and formoterol for 48 h, followed by a 48 h depuration period. Water and organism concentrations were quantified by liquid scintillation counting. The uptake and elimination rates were modelled simultaneously as specified in the OECD 305 guidelines<sup>3</sup> and a kinetic bioconcentration factor (BCF) estimated. Estimated BCFs remained below 200 for several compounds with varying hydrophobicity, indicating little bioconcentration-like effects occurred via water exposure. BCF studies in this organism enables a much simpler and less time consuming analysis than traditional fish bioconcentration studies. Such studies may provide insight in the future as to whether a compound has the potential to accumulate through biomagnification. This study contributes to the understanding of pharmaceutical toxicokinetics in *G. pulex* invertebrates and the method used may highlight

compounds that may be of particular concern during environmental risk assessment (ERA). References. Daughton, C.G. & Ternes, T.A. (1999). *Environ. Health Persp.*, 107(6), 907-938. van der Oost, R., J. Beyer, et al. (2003). *Environmental Toxicology and Pharmacology*, 13(2), 57-149. #### MO081

##### **A novel approach for reducing emissions of pharmaceuticals to the environment**

T.G. Bean, A. Boxall, University of York / Environment Department; E. Bergstrom, J. Thomas-Oates, The University of York / Chemistry; Z. Williamson, University of York / Environment; A. Colson, P. Bartl, Pyropure Ltd  
There is increasing interest over the impacts of pharmaceuticals on the natural environment. Inputs from inappropriate disposal of unused medicines and emissions from manufacturing plants are thought to be important pathways for pharmaceuticals to enter the environment. A recent survey that we conducted on what people do with unused medicines found that 30% of people questioned dispose of surplus medicines inappropriately and only 17% were aware of schemes that enable medicines to be returned of to the pharmacy for transportation to, and disposal in, a high temperature incinerator. By better managing unnecessary emissions, levels of pharmaceuticals in surface waters, groundwaters and soils could be reduced. Pyropure is a new small scale treatment unit that has the potential to destroy pharmaceutically contaminated wastes on site by processes of pyrolysis and gasification. While the system operates at around 550°C a temperature that should be sufficient to destroy many organic molecules, its efficacy for treatment of pharmaceuticals is unknown. This study therefore investigated the suitability of the Pyropure system for 17 of the most thermally stable pharmaceuticals that are currently in use. The system was applied to three waste scenarios containing the test substances: sharps waste bins containing needles and syringe bodies; pharmaceutical take back containing packaging and blister packs; and manufacturing waste to simulate waste from a production line. Samples of the effluent, settleable solids and gas emissions from the system were obtained and analysed for parent compounds and transformation products using a combination of LC-MS/MS and LC-FT-MS. Results suggest that Pyropure is an effective treatment process with in-excess of 99% of the applied pharmaceuticals destroyed for ten of the 17 and an average of 94% destroyed for the other seven. None of the ten active metabolites were detected in significant quantities (less than 0.6% of parent equivalent). Using the destruction level achieved by the PyroPure system the contribution to existing levels of pharmaceutical contamination in wastewater of a single PyroPure operating at full capacity was assessed. The outputs from the model suggest that future integration of the PyroPure system into a wider stewardship scheme could help to reduce the levels of pharmaceuticals in the environment whilst also reducing the economic and environmental costs of current waste management practices.

#### MO082

##### **Excipients from galenical pharmaceutical production in wastewater: overview and environmental risk assessment**

K. Wirz MA, F.Hoffmann-La Roche Ltd / Site SHE; M. Studer, F.Hoffmann-La Roche AG / Site SHE; J. Straub, F.Hoffmann-La Roche Ltd / Roche Group Safety Health Environmental Protection  
In galenical production, many excipients are processed for different purposes, in addition to the active pharmaceutical ingredients (APIs). Compared to the APIs, excipients are little investigated regarding their environmental impact and fate, even though some of them are used in large quantities. To investigate potential effects and risks to aquatic biota and the environment arising from excipients during galenical production, the chemical, physical and environmentally relevant properties, in particular biodegradability and toxicity towards aquatic biota, of different excipients were collated and a predicted no effect concentration (PNEC) was calculated where possible. Overall, 184 excipients were literature-searched for properties. Due to the fact that the database is insufficient, only half of the excipients allowed an aquatic PNEC calculation. Based on these parameters, for each of the 42 excipients currently used in galenical productions at Roche Basle and Roche Kaiseraugst, both in Switzerland, a predicted environmental concentration (PEC) was derived based on maximum daily loss of the single excipients to wastewater, derived by mass balance. Then, an environmental risk assessment comparing PEC and PNEC was conducted for the respective wastewater treatment plant (WWTP) and the receiving surface water, the River Rhine for both plants. Additionally, to simulate a theoretical worst case scenario, certain galenical productions where given excipients are used in the highest amounts were assumed to take place in parallel on the same day, resulting in increased excipient losses to wastewater. The PEC/PNEC risk characterisation ratios for the excipients currently used at Roche are well below 1 throughout. Together with the fact that based on biodegradability data many will be removed in the WWTP, this indicates that the excipients currently used do not present a risk to the environment. However, as the database is incomplete, environmental risks from excipients in galenical production in general should not be automatically considered to be negligible. Further work on excipients, specifically their biodegradability and effects on the environment, is needed to assemble a more solid and transparent database, in order to preclude adverse effects in WWTPs and receiving waters from galenical production.

#### MO083

##### **Toxicity of seaweeds from the Persian Gulf**

M. Yousefzadi, Marine Biology; S. Mashjoor, Hormozgan University; A. Naji,  
**Conclusion** the results obtained in this study showed that Ethyl acetate and methanol extracts of marine Macro algae *U. flexuosa*, *P. antillarum* and *P. boergesenii*, species used in this paper has a great potent for antimicrobial properties, in addition to cytotoxic activities. These data indicate the possibility that seaweeds and its constituents may be applied as drug (antibacterial and anticancer agent) for human administration.

## **Evolutionary, multigenerational and epigenetic effects of pollutants: scientific support to long-term ERA (P)**

#### MO084

##### **Genetic variation of *Lymnaea stagnalis* sensitivity to copper sulfate and its implication for toxicity testing**

M. Coutellec, INRA / Ecology and Ecosystem Health UMR INRA Agrocampus Ouest; J. Côte, INRA; A. Bouetard, INRA / Ecology and Ecosystem Health UMR INRA Agrocampus Ouest; Y. Pronost, INRA / Experimental Unit of Aquatic Ecology and Ecotoxicology; M. Coke, INRA; A. Besnard, INRA / UMR ESE 0985; F. Piquet, ISAE; T. Caquet, INRA / UMR ESE  
The use of monospecific standardized tests to assess the ecological risk of chemicals implicitly relies on the assumption that intraspecific variation in sensitivity is negligible in this context. First, this is a very strong hypothesis, and current research provides overwhelming evidences of significant variation among conspecific lineages in their ability to face environmental change and stress. Second, population response to stress has both a plastic and a genetic component, the latter, if additive, forming the basis for adaptive evolution. This means that population divergence in chemical sensitivity may be genetically fixed, as the result of exposure history (genetic adaptation). In this study, we investigated genetic variation in pesticide sensitivity of a non-target species, the freshwater snail *Lymnaea stagnalis*. We focused on a set of 64 lineages stemming from eight natural populations or strains found to be genetically differentiated at neutral markers and life history traits (for natural populations, see Bouétdard et al. 2014, PLoS ONE 9: e106670). Snails representative of at least the third generation born in the laboratory since initial sampling were exposed to copper sulfate at a concentration determined as global 96h LC50 (pilot experiment, all lines mixed up). Survival over time was modeled using a lognormal distribution (lowest AIC) and regressed on the model *chemical treatment x population + body size* (R function *survreg*). All effects were highly significant, except that of treatment by population interaction ( $p = 0.095$ ). However, copper sensitivity varied significantly among populations (Tukey post-hoc test; 96h survival: 50 to 90%, mean = 69.7%, SD = 12.6%), as did the daily death rate (8 to 25%; mean = 16%, SD = 5.2%). These findings clearly show that extrapolating results from “single-line” toxicity tests to the species level can lead to strongly biased conclusions. One possibility of improvement might be to explicitly include conspecific lines of various genetic origins in standardized testing procedures.

#### MO085

##### **Facing multiple stressors: Genetic variability and structure of a model freshwater population**

P. Inostroza, Helmholtz Centre for Environmental Research GmbH - UFZ / Effect Directed Analysis; S. Michalski, Helmholtz Centre for Environmental Research UFZ / Community Ecology; W. Brack, Helmholtz Centre for Environmental Research UFZ / Effect Directed Analysis; H. Norf, Helmholtz Centre for Environmental Research UFZ / River Ecology Aquatic Ecosystems Analysis and Management  
Multiple stressors including micropollutants are currently receiving growing interest due to increasing concerns about ecosystem health. Many of such multiple stressors occurring in the environment can exert strong effects on ecological communities as a consequence of both synergistic and antagonistic effects on organisms. In addition, they can also interact and induce unexpected consequences thereby changing natural dynamics. Field studies addressing ecological effects of multiple stressors, however, are scarce. Here we used the amphipod *Gammarus pulex* as a model to test the hypothesis that changes in the intraspecific structure of natural populations correlate with land-use driven factors such as the concentration of micropollutants. The hypothesis was tested by collecting seasonal samples of *G. pulex* from two agricultural and one natural stream in the Harz Mountains, Germany. In total 24 specimens per site and date were analysed using 18 microsatellite loci. Even if we found similar seasonal dynamics in the genetic structures of amphipod populations inhabiting natural and agricultural streams, we observed generally higher genetic diversity in agricultural than in natural streams. Our results emphasize the need for high temporal resolution when addressing stressor effects on the intraspecific structure of ecological populations.

#### MO086

##### **Epigenetic memory of environmental stressors in *Daphnia magna***

C. Goncalves Athanasio, University of Birmingham / Biosciences; L. Mirbahai, The University of Birmingham / School of Biosciences; S. Parameswaran, C.

Gopalakrishnan, Genotypic Technology Pvt Ltd; M.R. Viant, University of Birmingham / School of Biosciences; J. Chipman, The University of Birmingham / School of Biosciences

Cytosine methylation plays an important role in regulation and stability of gene expression, providing a cellular memory especially for long-term silencing of genes. It is well known that several pollutants can modify epigenetic marks which can lead to changes in gene expression and potential to cause adversity. The epigenetic changes can be maintained throughout lifetime, and potentially beyond into subsequent generations, emphasizing the concept of epigenetic memory. It is proposed that class-specific alterations to the normal pattern of DNA methylation may occur due to chemicals and other stressors, offering a unique opportunity to provide a lifetime-history of an organism's prior exposure to factors influencing the epigenome. Thus, the use of epigenetic profiles may provide a system to reflect early- or long-term exposures to stressors, and have utility as a novel tool for environmental monitoring. To explore these hypotheses, *Daphnia magna* was exposed for 14 days to sub-lethal concentrations of 5-azacytidine (a demethylating agent;  $3.7\text{mgL}^{-1}$ ), arsenic (a carcinogen known to modulate the epigenome;  $100\mu\text{gL}^{-1}$ ) and hypoxia (an environmental stressor;  $< 2\text{mgL}^{-1}$ ). Life-history traits along with haemoglobin quantification were used to identify the effects of the stressors on the organisms. Whole-genome bisulphite sequencing (WGBS) was used to identify modified DNA methylation profiles. The sustained exposure of adult daphnids to either 5-azacytidine or hypoxia caused a decrease in the growth rate of the subsequently obtained third brood compared with controls. *Daphnia* exposed to hypoxia also presented a 2-fold increase in haemoglobin concentration compared with normoxic conditions. In contrast, no effects on body length of the derived brood was observed following exposure of the parent animals (or the brood themselves) to arsenic. WGBS enabled the characterisation of the profile of methylated cytosines across the genome of the exposed adult daphnia. Global methylation level was approximately 0.4 % and this global level was not significantly altered in response to any of the above treatments. The sequencing data are now being interrogated to determine if the intriguing possibility of gene-specific epigenetic modifications occur and, if so, to determine the persistence of such changes. The study thus tests if stress-specific DNA methylation profiles might present an opportunity to be used for identification of history of adverse exposures.

#### MO087

##### **Multigenerational effects of *Daphnia magna* exposed to polluted field water**

N. Chatterjee, S. Choi, S. Lee, University of Seoul; J. Choi, School of Environmental Engineering Graduate School of Energy and Environmental system Engineering

In agreement with the thoughts that multigenerational and/or micro-evolutionary effects of chemicals should be incorporated in risk assessment, we, herein, report a comprehensive study with different phenotypical as well as physiological responses of *Daphnia magna* cultured in field water which was collected from surface stream water with industrial as well as natural contaminants. Phenotypical and physiological responses of *Daphnia* cultured in polluted field water were compared with those cultured in standardized *Daphnia* media (i.e. M4 media). On one hand, increase in body size, spine length, reproduction rate, hemoglobin formation were observed, on the other hand, slower movement and decrease in heart rate were evident in field water exposed animals. The possible correlation of molecular mechanism and phenotypical phenomena is currently ongoing in our lab. Taken together, our results present a paradigm not only of multigenerational exposure-effect quantification but also add another important layer of observation about complex mixture stressors with real field water. #### MO088

##### **Multi-generational effects of nanoparticles on *Caenorhabditis elegans***

S. Kim; J. Moon, Konkuk University; Y. An, Konkuk University / Department of Environmental Science

The nematode *Caenorhabditis elegans* is a key species used in nano-toxicity assessment. They normally lay embryos that hatch outside the body, but embryos are often retained and hatched inside the parental body, a phenotype called a "bag of worms" (BOW). On nanoparticle exposure condition, this phenomenon can induce the fetal-exposure to next generation from the bio-distributed particles in parent body. In the present study, we suggest the evidences of multi-generational effects and generation transfer in *C. elegans* following core-shell quantum dots (CdSe@ZnS, QDs) maternal food exposure. The parent generation (F0) worms exposed to QDs with food source (*Escherichia coli*, strain OP50), and first generations (F1) were classified by the different production time (before, or after lethal BOW). Then the worms maintained on NPs-free conditions, and the various endpoints such as survival, reproduction, aging phenotype, oxidative stress, and intestinal fat storage were evaluated. We observed the changes of QDs bio-distribution in F0 by BOW occurrence, and the particles were transferred to next generation, F1 in parent body. This F1, which produced after lethal BOW, showed the significant decreased reproduction rates compared to control group, and the intestinal fat storages were lacked. And these effects continued on multi-generational levels (F2-F3). Many previous studies about multi-generational effects or NPs generation transfer have been reported, but there were no study with

suggestion of both evidences at the same time. Our results showed the evidences that the multi-generational effects can be induced on by NPs transfer, and these effects caused by deficiency of fat storage. *This research was supported by Basic Science Research Program through the National Research Foundation of Korea(NRF) funded by the Ministry of Education(2013R1A1A2061386).*

#### MO089

##### **Exposure of zebrafish to morphine during first day of development results in modulation of innate immune system responses at later stages**

H. Mottaz, Eawag / UTOX; R. Schoenenberger, Eawag, Aquatic Research / UTOX; R.I. Eggen, Eawag / Department of Environmental Toxicology; K. Schirmer, Eawag / Environmental Toxicology; K.J. Groh, Eawag / UTOX Environmental Toxicology

Opioid drugs, such as morphine (MO), are detected at concentrations up to  $1\mu\text{g/L}$  in waste and surface waters worldwide, as a consequence of both licit and illicit use. These compounds may pose a risk to aquatic organisms due to their semi-persistence and potency, in particular to fish due to conservation of molecular drug targets across vertebrates. In mammals, MO is known to influence not only behavior but also the immune system and epigenetic regulation. We have recently observed that continuous exposure to MO from 1 hour post fertilization (hpf) to 4 days post fertilization (dpf) modulates the innate immune system responses in zebrafish (*Danio rerio*) embryos, as assessed by bacterial lipopolysaccharide (LPS) challenge assay. Exacerbation of LPS-induced inflammation and immunosuppressive effects were seen at lower and higher MO concentrations, respectively. These could be explained by the observed downregulation of several relevant genes, including MYD88, TRIF, TRAF6, p53, p38, NF $\kappa$ B2, IL1 $\beta$ , IL6, IL8, CC-Chemokine and iNOS, as well as ABC transporters, assessed by RT-PCR. In this study, we set out to investigate whether shorter exposure to MO during early life would be sufficient to evoke similar effects at later stages. The embryos were exposed to MO from 1 hpf to 26 hpf, followed by washing and raising in clean medium until gene expression analyses or LPS assay at 4 dpf. We observed that short-term early life exposure to MO resulted in gene expression changes similar to those seen after continuous exposure. Moreover, modulation of responses to LPS followed similar patterns. Previous studies reported that MO is cleared out from adult zebrafish within 1 day after waterborne exposure, indicating that the effects we observed may be due to persistent effects of MO on gene expression induced during short-term early life exposure. Ongoing work focuses on MO uptake and depuration kinetics in zebrafish embryos. If the depuration of MO by 4 dpf where gene expression is assessed will be confirmed, the potential epigenetic effects of MO will be investigated using bisulfite sequencing to assess the promoter methylation status of relevant genes. This work demonstrated that short-term exposure of zebrafish to MO during early life potentially modulates innate immune system responses at later stages, raising concerns about potential adverse effects on the fish immune system following short-term exposure of sensitive life stages to environmentally present opioid drugs.

#### MO090

##### **DNA alterations and effects on growth and reproduction in *Daphnia magna* during chronic exposure to gamma radiation over three successive generations**

F. Parisot, IRSNRP-ENVLECO / LECO; J. Bourdineaud, Géochimie et Ecotoxicologie des Métaux dans les systèmes Aquatiques; C. Adam-Guillermin, IRSN; F. Alonzo,

Anthropogenic activities related to the nuclear industry contribute to continuous discharges of radionuclides into terrestrial and aquatic ecosystems. Over the past decade, the potential risk of ionizing radiation for natural biota has become a growing public, regulatory and scientific concern. Until recently, ecological risk assessments of ionizing radiation have mainly been based on chronic effects measured over exposure durations, which are not really relevant of realistic environmental conditions. In fact, studies involving several generations remain scarce, although they give a better understanding of the long-term effects of low doses of ionizing radiation to adequately protect the environment. In this context, the present study examined chronic effects of external Cs-137 gamma radiation over three successive generations (F0, F1 and F2) of the cladoceran crustacean, *Daphnia magna*. The objectives were threefold: (i) to examine whether environmentally relevant dose rates of gamma radiation (from 0.007 to 35.4 mGy h $^{-1}$ ) induced increasing effects on survival, growth and reproduction over generations, (ii) to test a possible accumulation and transmission of DNA alterations from adults to offspring and (iii) to compare responses to chronic gamma radiation between the molecular and organismal levels of biological organization. Results showed a significant reduction in brood size in generation F0 at 35.4 mGy h $^{-1}$  and a significant increasing delay in growth and brood release from 0.070 mGy h $^{-1}$  in generation F2. Only a slight reduction of fecundity was recorded at 35.4 mGy h $^{-1}$  in F1. In parallel, DNA alterations became significant at decreasing dose rates over the course of F0 (from 4.70 mGy h $^{-1}$  at hatching to 0.007 mGy h $^{-1}$  after 21 days) and from F0 to F2 (0.07 mGy h $^{-1}$  at hatching to 0.007 mGy h $^{-1}$  after 21 days). In F1, DNA alterations were significant at highest dose rates only. This study suggested that an accumulation and transmission of DNA alterations occurred from F0 to F2, together with an increase in effect severity on growth and reproduction. Transiently more efficient DNA repair leading to some recovery at the organism level was suggested in F1. A DEBtox model is developed to mechanistically

describe how an accumulation and transmission of DNA alterations can explain changes in growth and reproduction effects over successive generations and explore the metabolic mode of action associated with gamma radiotoxicity.

#### MO091

##### **Effects of an environmental relevant concentration of carbendazim on twelve generations of *Daphnia magna***

A.R. Silva, University of Aveiro / Dept of Biology CESAM; D.N. Nunes Cardoso, CESAM, University of Aveiro / Department of Biology and CESAM Centre for Environmental and Marine Studies; A.S. Cruz, CESAM & University of Aveiro / Biology; S. Mendo, University of Aveiro / Department of Biology CESAM; A.M. Soares, Universidade de Aveiro / Department of Biology and CESAM; S. Loureiro, Universidade de Aveiro / Biology

In the environment, organisms can be exposed to chemicals continuously or for a long-term. Due to runoff from agriculture fields, pesticides may appear in surface waters and contribute to this long term-exposure. Carbendazim is one of the pesticides that has been detected at concentrations near 5 µg/L, as it is a fungicide widely used in agriculture in plant production products, including fruit trees, cereals, vegetables, etc. Therefore, testing effects throughout several generations of organisms can be a good epigenetic approach to evaluate these long-terms exposures. Daphnids can thus be good models due to their parthenogenetic reproduction, where there is no recombination, and consequently no interference of genetic variability between organisms. Considering this, *Daphnia magna* was exposed to an environmental relevant concentration of carbendazim (5 µg/L) for twelve generations, simulating an ecological relevant scenario. The aim of the present study was to investigate the effect of carbendazim on successive generations of *D. magna*, considering the effects of the contaminant in the offspring, when parents were pre-exposed to the pesticide. For that, currently used ecotoxicity tests (e.g. immobilisation, feeding inhibition or reproduction tests) and a genotoxicity test (the comet assay) were carried out throughout generations exposed to carbendazim. The obtained results indicated that there were differences on carbendazim sensitivity upon exposure of daphnids born in clean medium and daphnids born in medium already containing carbendazim, at all endpoints tested (except in the immobilisation data). In addition, DNA damage was higher in generations of daphnids born in carbendazim (comparing with the ones born in clean medium) and DNA damage appeared to be transferred from mother to the offspring along the generations, but it also increased from generation to generation.

#### MO092

##### **Blame your parents! Parental experience impacts progeny response to municipal wastewater effluent exposure.**

M. Fuzzen, H. Dhiyebi, University of Waterloo / Biology; L. Bragg, University of Waterloo / Department of Biology; G. Tetreault, University of Waterloo / National Water Research Institute; M.E. McMaster, Environment Canada / National Water Research Institute; M.R. Servos, University of Waterloo / Department of Biology Over 30 fish species have been reported to show an intersex condition (ova-testes) after exposure to municipal wastewater effluent (MWWE), suggesting that the feminization of male fish is a widespread phenomenon. The Grand River watershed in southern Ontario, Canada is home to one million people serviced by 30 municipal wastewater treatment plants (MWWTPs). The Kitchener MWWTP is the largest of these plants (serving >100,000 people) and previous studies have shown that male rainbow darters (*Etheostoma caeruleum*) collected near this plant are feminized, have reduced fertilization success, and reduced progeny survival to hatch. While it is well recognized that MWWE has direct impacts on the sexual development and performance of the F0 generation, little is known about the consequences of MWWE exposure on subsequent generations of fish. The purpose of this study was to determine whether parental exposure history had an impact on the response of larvae to subsequent exposure. Progeny of rainbow darter collected from sites of various degrees of urban and MWWE exposure were exposed to either de-chlorinated tap water (control), 10% MWWE, or 10 ng/L ethinylestradiol (EE2) from 21 to 100 days post hatch (dph). Survival, growth, and sexual maturation of larval fish were measured at 100 dph. In general, exposure of larval rainbow darter to either EE2 or MWWE had no impact on survival. Parentage however had an impact on survival. At 21 dph and 100 dph, larvae whose parents were collected downstream of the Kitchener MWWTP had decreased survival compared to larvae whose parents were collected upstream of the urban area. An increase in the length, and weight of the fish was found in EE2 and MWWE exposed fish compared to the control group. In contrast, condition was significantly lower in the EE2 and MWWE exposed groups compared to controls. Additionally, larvae with parents from upstream of the urban limits had higher condition in the control treatment compared to any treatment or parental group. While exposure to EE2 resulted in a completely female population in larvae, there did not seem to be an impact of parental or MWWE exposure on sex ratio in this study. This study suggests that parental exposure has implications for progeny survival and fitness. Future work will compare the sexual development and molecular sensitivity of progeny from different parents to MWWE exposure.

#### MO093

##### **Development of new microsatellites markers to investigate genetic diversity between metallicolous and non-metallicolous earthworm populations.**

D. SOULEMAN, University of Lille1; M. Pauwels, University of Lille1 /

Laboratoire de Génétique et Evolution des Populations Végétales; F. Grumiaux, LGCgE - EA 4515; H. Frerot, University of Lille1 / Laboratoire de Génétique et Evolution des Populations Végétales; F. VANDENBULCKE, LGCgE, Université de Lille 1 / LGCgE EA Univ Lille Fonctionnement des Ecosystèmes Terrestres Anthropisés Cité Scientifique SN Rdc F Villeneuve d'Ascq France

Anthropic activities can result in heavy metal contamination of urban and agricultural soils. Pollution may induce changes in organisms living in close contact with soil. Biological responses observed at the individual or infra-individual level of biological organization led to the development of biomarkers which consists often in evidencing biological modifications following a contaminant stress in laboratory conditions, using naïve organisms and it is sometime proposed to use the biological state of individuals from sentinel species collected in the field to evaluate the level of environmental exposure. However, considering the possibility of local adaptation following long-term exposure, response of organisms sampled in the field may substantially differ from laboratory specimens. In a recent review, we investigated this point focusing on the definition and validity of molecular biomarkers of metal pollution using earthworms of the Lumbricidae family. It appears that conditions for local adaptation to occur are present in earthworms. Some infra-individual evidence of adaptation obviously exists. Consequently, there is need for evolutionary studies investigating the level and distribution of genetic diversity in natural populations of earthworms. Therefore, it seems necessary to integrate the potential effects of local adaptation to MTEs on biological responses of organisms in the development of biomarkers. Three species of Lumbricidae family belonging to two ecological groups were chosen for this study. *L. terrestris*, an anecic earthworm. *L. rubellus* and *L. castaneus*, epigeic earthworms. In this work, we decided to investigate a possible local adaptation, owing to pollution, in earthworms from Lumbricidae family populations using microsatellite markers approach. Microsatellite markers may provide data to investigate the genetic differences between earthworm populations issued from polluted and reference sites. Eight microsatellite markers were identified in *L. terrestris*. Same approach of microsatellite identification is ongoing in *L. rubellus* and *L. castaneus*. Microsatellite markers are essential tools to understand the evolutionary dynamics of populations and direct and indirect selective forces that shape genetics variation in natural populations. We hypothesized that probable loss of genetic variation may occur due to selection pressure and genetic drift in population belong to polluted area.

##### **Miniaturized in-flow sorter for dispensing fertilized zebrafish embryos for ecotoxicity biotests**

N.M. Fuad, J. Skommer, RMIT University / School of Applied Sciences; T. Friedrich, University of Massachusetts / Department of Molecular and Cellular Biology; J. Kaslin, Monash University / ARMI; D. Wlodkovic, RMIT University / School of Applied Sciences

The current bottleneck in using zebrafish embryos for screening purposes is a tedious manual evaluation to confirm the fertilization status and subsequent dispensing of single viable embryos to multitier plates to perform toxicity analysis. Manual procedures associated with sorting hundreds of embryos are very monotonous and as such prone to significant analytical errors due to operator's fatigue. This work presents a proof-of-concept design of a continuous flow embryo sorter capable of analysing, sorting and dispensing objects ranging in size from 1.5 – 2.5 mm such as zebrafish embryos. The major obstacle hampering sorting of millimetre sized particles such as zebrafish embryos on chip-based devices is their substantial diameter (above one millimetre), mass (above one milligram), which both lead to rapid gravitational-induced sedimentation and high inertial forces. In this work, we present an innovative design of a micromechanical large particle in-flow sorter (MILPIS) capable of analysing, sorting and dispensing living zebrafish embryos for ecotoxicity testing applications. The system consisted of a microfluidic network, revolving micromechanical receptacle actuated by robotic servomotor and opto-electronic sensing module. The prototypes were fabricated in poly(methyl methacrylate) (PMMA) transparent thermoplastic using infrared laser micromachining. Elements of MILPIS were also fabricated in an optically transparent VisiJet resin using 3D stereolithography (SLA) processes (ProJet 7000HD, 3D Systems). The device operation was based on a rapidly revolving miniaturized mechanical receptacle. The latter function was to hold and position individual fish embryos for (i) interrogation, (ii) sorting decision-making and (iii) physical sorting. The actuation of the revolving receptacle was performed using a Dynamixel AX12A and RX24F (Robotis Inc, Korea) robotic actuators. The system was designed to separate fertilized (LIVE) and non-fertilized (DEAD) eggs, based on optical transparency differences using infrared (IR) emitters/receivers embossed in the microfluidic chip-based system. Digital storage oscilloscope (DSO) signals were used to distinguish the diffraction characteristics of LIVE vs. DEAD embryos and a voltage threshold was set trigger the actuation of the revolving receptacle.

#### MO095

##### **ZebraToxChip - Microfluidic technology for automation of fish embryo toxicity (FET) biotests**

F. Zhu, J. Skommer, RMIT University / School of Applied Sciences; T. Friedrich,

University of Massachusetts / Department of Molecular and Cellular Biology; J. Kaslin, Monash University / ARMI; D. Wlodkowic, RMIT University / School of Applied Sciences

Fish Embryo Toxicity (FET) biotest has gained popularity as one of the most promising alternative approaches to acute fish toxicity tests. At present, the major hurdle to widespread deployment of FET in large-scale water-born toxicity projects is the lack of enabling high-throughput analytical platforms. Despite the importance and common acceptance of FET, most experiments that utilise zebrafish embryos and larvae are still performed in multi-well plates and require laborious and time-consuming manual manipulation of specimens and solutions. Furthermore, static culture of embryos and larvae can lead to a bias in toxicity studies due to e.g. drug adsorption to the surfaces and also secondary effects from the secreted embryo metabolites. Lastly, microtiter plate culture is not conducive to precise specimen positioning and immobilization, both necessary for applications such as high-resolution imaging, electrophysiology measurements, or precise anatomical mapping of physiological processes. In order to spearhead deployment of FET in large-scale ecotoxicity studies, automated platforms are needed to integrate embryo in-test positioning and immobilization (suitable for high-content imaging) with fluidic modules for continuous toxin and oxygen delivery to embryos. This work describes design and validation of a pioneering and high-throughput Lab-on-a-Chip technology for automation of zebrafish embryo toxicity (FET) biotests performed in ecotoxicology. The innovative device supports rapid loading and immobilization of large numbers of fish embryos suspended in a continuous microfluidic perfusion as a mean of toxin delivery. The 3D high-density LOC array was fabricated in poly(methyl methacrylate) (PMMA) transparent thermoplastic using infrared laser micromachining while the off-chip interfaces were fabricated using additive manufacturing processes. The system's design facilitates rapid loading and immobilization of a large number of embryos in predefined clusters of traps during continuous microperfusion of toxicants. The system supports real-time in situ analysis of developing embryos. Moreover, a miniaturized 5MP USB fluorescent microscope was integrated for low-resolution and low-cost imaging together with solid-state LED illumination. A PC-computer and interconnected embedded ARM microcontroller controlled all sensor inputs and actuator outputs. This system brings us a step closer to realization of full analytical automation in ecotoxicology.

#### MO096

##### Glial toxicity of CdCl<sub>2</sub> in zebrafish brain

A. Monaco, A. Aurino, M.C. Grimaldi, I. Ferrandino, University of Naples Federico II / Biology

Cadmium (cd) is known as a potent toxic metal and a significant aquatic and terrestrial environmental pollutant. In this study was verified the ability of cadmium chloride (CdCl<sub>2</sub>) to induce cytotoxic effects on the brain of zebrafish through the detection of the expression of glial fibrillary acidic protein (GFAP), astroglial marker. It was also carried out a staining method with methasol fast blue for the evaluation of the myelin integrity. Specimens of adult zebrafish were exposed for 16 days to 1.0 mg/L of CdCl<sub>2</sub>, a concentration of cadmium observed at some sites affected by industrial pollution, and the brains were analyzed after 2, 7 and 16 days of exposure. By western blotting experiments a decrease in the levels of GFAP was observed after 2 days in the order of 40% compared with the control. This decrease arrived to be 50% after 16 days. A reduction of GFAP positive fibers was revealed by ABC technique in the brain of the fishes treated compared to that of the controls, in all three times tested, with a progressive trend. After 2 days of treatment was observed a reduction in the level of positivity at ventricular and pial surface. The affected areas were the midbrain and the medulla oblongata. A reduced immunoreactivity was also found after 7 days in the cerebellum, medulla oblongata and ependima, while after 16 days in addition to the cerebellum and the medulla oblongata a low expression of the protein was observed also in the telencephalon. The methasol fast blue staining showed a reduction of affinity to the dye after 7 and 16 days of exposure in neurons axons of medulla oblongata, optic tectum and cerebellum. These data confirm the toxic action performed by cadmium in the brain, highlighting the effects on macroglial cells, key components for the function of SNC. The toxic role of cadmium on myelin integrity was already showed as well as the impairment of this in GFAP null models, so the deconstruction of astroglial processes could be the link between cadmium and myelin diseases.

#### MO097

##### NEUROTOXICITY INDUCED BY ALCL<sub>3</sub> IN ZEBRAFISH BRAIN

A. Monaco, A. Aurino, M.C. Grimaldi, I. Ferrandino, University of Naples Federico II / Biology

The aluminum (Al) is one of the most abundant elements in the Earth's crust, it accumulates in the human body, including the CNS. The exposure to this metal is considered a causative factor for the development of Alzheimer's disease, a disease that affects mainly the cerebral cortex, the amygdala and the hippocampus, structures that find their counterpart in the telencephalon of Zebrafish. The mechanisms by which aluminum interacts with the nervous system, however, are understood only in part. To test the toxicity of Al on the telencephalon of Zebrafish and verify its ability to induce neurodegeneration in this fish, adult individuals were exposed for 7 days at 100 µg/L of aluminum chloride (AlCl<sub>3</sub>) at pH 5.8. Brains were removed after 2 and 7 days after initiation of treatment. To evaluate the presence of histomorphological alterations were made staining as hematoxylin-eosin and Cresyl Violet and immunohistochemical experiments performed on serial

transverse sections of the forebrain by ABC method using an anti-Aβ<sub>42</sub> antibody. The stainings performed on cross sections of the Zebrafish telencephalon have shown tissue alterations already after 2 days of exposure to AlCl<sub>3</sub>, consisting in dilations of the cerebral parenchyma and vacuoles present in pericellular area at support of possible vascular damage induced. Immunohistochemistry analysis showed in the telencephalon of individuals of control a faint signal at the level of cell bodies of nerve cells that show abundant cytoplasm. The signal was incremented at the intracellular level after 2 and 7 days after start of treatment, a phenomenon that might therefore be associated with an increase in the presence of oligomers of amyloid peptide inside the cells, characteristic of the early stage of Alzheimer's disease as well as other neurodegenerative diseases. These data confirm the toxic action exerted by Al on the brain and show a correlation between this metal and existing mechanisms at the basis of neurodegenerative diseases even in this fish. The results obtained thus open the way for further analysis aimed at further confirmation of the use of this model for the study of neurodegenerative mechanisms induced by this metal.

#### MO098

##### ALUMINUM-INDUCED ALTERATIONS IN DANIO RERIO DEVELOPMENT

A. Monaco, A. Aurino, M.C. Grimaldi, I. Ferrandino, University of Naples Federico II / Biology

The use of zebrafish embryos and larvae is always more widespread and accepted in the scientific community for the screening of dangerous effects exercised by chemicals and environmental pollutant on the development of vertebrate organisms. Metals as aluminum (Al), one of the more abundant metal in the Earth's crust, have been previously associated with the development and the progression severity of neurological disorders as Alzheimer's diseases. In this study the toxicity of Al was evaluated on the development of the zebrafish larvae, paying particular attention to the nervous system. Larvae at protruding mouth stage were exposed to different concentrations of aluminum chloride (AlCl<sub>3</sub>) for 72 hours to test the lethality index. The mortality and the phenotypic analysis were determined after 24, 48 and 72 hours of treatment. Pericardial edema and impaired cardiac function consistent in alteration of heart rate were present in 50% of these larvae after 48 hours. A reduction of the response to stimuli in live larvae was observed from 100 µM of AlCl<sub>3</sub> just after 24 hours of the exposition and the severity of this abnormality was directly proportionate to the used concentration. In the light of these results sections of zebrafish larvae, after 48 hours of the exposure at 100 µM of AlCl<sub>3</sub>, were embedded in paraffin and processed by ABC technique. The immunohistochemistry experiments performed with an antibody anti-GFAP, marker of astroglial cells, showed a reduction of signal in terms of intensity and number of positive cells, in all areas of larvae encephalon with largest decreases in the hindbrain. These data show a toxic effect exerted by Al on the development of the larvae of this teleost fish. Interesting was to observe that this metal could represent also a cardiac toxin over the neurotoxic ability that also in this study was confirmed. The decrease of GFAP expression was associated in previous works with deconstruction of cellular cytoskeleton resulting in degeneration of cellular processes and functionality, so Al could affects the roles performed by these cells also in this model. Affecting astroglial roles Al should damages therefore nerve cells, and this observation can represent a new way to consider for explain the neurological toxicity exercised by this metal in human brain.

#### MO099

##### Effects of exposure to metals in Zebrafish (Danio rerio) embryos

A.S. Sobrino-Figueroa, Universidad Autonoma Metropolitana Iztapalapa / Hidrobiologia Laboratorio Alejandro Villalobos

The metals As, Cd, Cr, Cu, Hg, Mn, Ni, Pb, V and Zn are found in high concentrations in some aquatic systems the Valley of Mexico, due to the discharges of untreated wastewater, from industrial, domestic and agricultural activities. In this paper an evaluation of the toxic effect and the degree of lipid peroxidation caused by Arsenic, Cadmium, Chromium, Copper, Mercury, Manganese, Nickel, Lead, Vanadium and Zinc metals in zebrafish embryos was performed to compare its sensitivity with *Daphnia magna* neonates, a species that is used for the evaluation of toxicity of effluents (NMX-AA-087-1995-SCFI). Bioassays with duration of 48 hour were performed, with 5 concentrations of each metal in triplicate (0.01, 0.1, 1.0, 10 and 30 ppm for Cd, Cr, Cu, Pb and Hg. And 6.25, 12.5, 25, 50 and 100 ppm for As, Mn, Ni, V and Zn) plus a control. LC<sub>50</sub> was determined after 48 hours exposure by the Probit method. The degree of lipid peroxidation in the tissues of embryos was evaluated by measuring the concentration of MDA (malondialdehyde). The metals with oxidative effects were Cd and Cu. The toxicity of metals was (LC<sub>50</sub> highest to lowest toxicity): Cu > Hg > Pb > Cr > As > V > Ni > Mn > Zn. *Danio rerio* embryos were more sensitive to Mercury compared with *Daphnia magna* neonates and had similar sensitivity to Copper. The LC<sub>50</sub> value for Copper (LC<sub>50</sub> = 0.092 ppm) obtained in tests with zebrafish embryos was lower compared to that established in NOM 001-SEMARNAT (4-6 ppm) for discharges in aquatic systems, for this reason it is important to continue research and monitoring to detect responses that indicate possible damage to fish stocks by the action of the discharges, to prevent irreversible deterioration of the stocks in the medium and long term.

#### MO100

#### **Acute, developmental and biochemical responses of *Danio rerio* embryos exposed to Bisphenol A: a comparative approach using Species Sensitivity Distributions**

S. Silva, University of Brasilia / TOXICOLOGICAL GENETIC; R. Oliveira, University of Brasilia / Department of Genetics and Morphology; A. Andrade, Universidade de Brasília Gtox / Departamento de Genética e Morfologia; K. Py-Daniel, Universidade de Brasilia / Departamento de Genética e Morfologia; C.K. Grisolia, University of Brasilia / Department Genetics and Morphology

Bisphenol A (BPA) is a chemical widely used in the manufacture of polycarbonate plastics and epoxy resins. The presence of BPA in aquatic ecosystems is often associated to discharge on municipal wastewater effluents and leachate from landfills. Considering previous measurements of environmental concentrations of BPA in the Paranoa Lake (Brasilia-Brazil), the present study intends to contribute to fill the gap on BPA toxicity to fish species considering a tropical scenario. Here, were studied the toxic effects of BPA on *Danio rerio* embryos using different endpoints (mortality, enzymatic biomarkers, development, and vitellogenin- VGT). The results were compared among several fish species by means of a Species Sensitivity Distributions. The fish embryos assays were based on the OECD protocol No. 236. For each assay, test solutions were prepared by successive dilution of the stock (5 mg/L - BPA 99% of purity from Sigma Aldrich). In order to evaluate the BPA stability, exposure solutions (400 ml in quadruplicate) were spiked with BPA and placed at the same experimental conditions of the ecotoxicological tests. BPA quantification was performed daily using the high performance liquid chromatography coupled to fluorescence detector. Embryo toxicity test was evaluated with newly fertilized eggs exposed to 0, 1, 2, 4, 10, 21, 46 and 100 mg/L of BPA. A similar test was performed for collection of embryos for biomarker analyses, using sub lethal BPA concentrations (0.35, 2.02, 11.68, 67.45, 389.63 and 2250.6 µg/L). The tests were carried out at  $26 \pm 1$  °C, 12 h light for 96 hours. Over 80% of nominal concentrations of BPA were detected in the test solutions during 4 days, indicating low degradation of the compound. After 48h exposure an LC50 = 13.5 mg/L was obtained and effects on hatching (LOEC = 10 mg/L), pigmentation and craniofacial formation (LOEC = 22 mg/L) were also observed. Alterations in the enzymatic level were noticed for embryos exposed to low BPA concentrations. VTG alterations observed were compared among several fish species and seem to be the most sensitive endpoint to BPA (HC5 < 10 µg/L) in acute scenario (1-10 days) evaluation. In this study, we observed that BPA showed low acute toxicity to *D. rerio* embryos, however, sub lethal ecotoxicological research on BPA indicates the necessity to regulate its use and control the concentrations of this contaminant in aquatic environments.

#### **MO101**

##### **Biological activity and transcriptomic alterations induced by particle-bound Polycyclic Aromatic Hydrocarbons from the Mediterranean and Black Seas atmosphere.**

S.R. Mesquita, Center of Marine and Environmental Research CIIMAR / METOX Coastal and Marine Environmental Toxicology; J. Dachs, IDAEA-CSIC / Environmental Chemistry; B.L. van Drooge; C. Barata, CSIC / Environmental Chemistry; N. Vieira, CIIMAR and Faculdade de Ciências da Universidade do Porto; L. Guimaraes, CIIMAR University of Porto / METOX Coastal and Marine Environmental Toxicology; B. Pina, IDAEA-CSIC / Environmental Chemistry

Combustion-generated polycyclic aromatic hydrocarbons (PAHs) are toxic compounds that bind to the soot carbon of air particles (particle matter, PM), persisting further on the environment. Even though the atmospheric deposition is one of the major sources of PAHs contamination to aquatic systems, the potential toxic burden of ambient PM to the aquatic biota is still unstudied. On the present work, organic extracts of atmospheric PM samples from the Mediterranean and Black Seas were first screened with a yeast-based assay for dioxin-like activity (AhR-RYA), and then tested on zebrafish embryos for embryotoxicity (ZET assay) and quantitative analysis of the expression of genes of interest. AhR-RYA showed high variability within the different sub-basins, in agreement with the high variability of particulate PAHs concentrations. No phenotypical effects on the ZET assay were observed, but the expression of genes related with oxidative stress response and development (*hao1*, *tr*, *ela2* and *klf2a*) was upregulated. The transcriptomic alterations, as well as the AhR-RYA activity, were maximal for the Black Sea and SE Mediterranean Sea, correlating with heavier PAH congeners. This study shows that even the reduced concentrations of heavy PAHs present in the atmosphere of open marine environments may be biologically active, possibly contributing to the toxic burden of aquatic organisms. *Acknowledgements - This study was supported by the Spanish Ministry through the project TEA-PARTICLE (CGL2011-29621; 2011–2013), and the Portuguese Foundation for Science and Technology for the doctoral grant of Sofia R. Mesquita (SFRH/BD/80710/2011) funded by the Program POPH - QREN through the Portuguese Ministry of Education and Science and the European Social Fund, and support through project PEst-C/MAR/LA0015/2013.*

#### **MO102**

##### **Histopathological changes of the gills of common carp (*Cyprinus carpio* L.) as a marker of environmental conditions in pond aquaculture**

B. Raskovic, University of Belgrade / Institute of Animal Science; M. Stankovic, Z. Dulic, University of Belgrade / Faculty of Agriculture; I. Zivic, University of Belgrade / Faculty of Biology; Z. Markovic, V. Poleksic, University of Belgrade /

Faculty of Agriculture

For decades, histopathological parameters (HP) were used as a pollution marker in ecotoxicology. The method is cheap, reliable and provides good insight into morphology of vital organs. The results obtained usually correlate with the pollution state of investigated ecosystem. We used HP changes of the gills of common carp (*Cyprinus carpio* L.) in order to monitor general fish health in pond aquaculture using a semiintensive system. In this system, fish is reared in earthen ponds; water supply is from the nearest river or stream. Since these ecosystems are man-made and man-maintained, the water quality is monitored. A field studies were conducted to compare gill HP of carp reared on 3 fish farms with different water supply: one was considered as a control - a fish farm of the Faculty of Agriculture in Belgrade school estate (CON), supplied with well water; other two commercial fish farms used water from nearby currents. Water supply for Kanjiza fish farm (KAN) was from the Tisza River, while for the fish farm Vrsacki Ritovi (VRT) it was Danube-Tisza-Danube canal. During one growing season, one-year common carp juveniles were collected every fortnight, from the same ponds of each farm. The second gill arch was fixed in 4% formaldehyde, and processed in routine HP protocol, stained with hematoxylin and eosin. The frequencies of lesions were calculated and compared between farms using Mann-Whitney U test. Water samples were also taken fortnightly: temperature, pH, DO, ammonium ions, and nitrates were measured. The fish at all fish farms showed a distinctive HP response to pond conditions: focal hyperplasia, lifting of the respiratory epithelium and hyperemia of gills prevailed. The majority of other lesions were circulatory changes: aneurism, blood stasis and lamellar telangiectasia. Severe changes, such as necrosis or complete lamellar fusions were also found, but to a lower extent. Analysis of HP results between farms provided clear difference: all changes were lower at CON, compared to KAN and VRT. VRT fish had higher frequencies of majority of lesions compared to KAN. Water quality did not differ greatly between farms. Differences in studied ponds ecosystems and rearing conditions (stocking density and dimension of the ponds) including possible sub lethal pollution coming from the farm water supply could explain differences in gill HP and indicate risks for the reared fish health status, and therefore production result.

#### **MO103**

##### **Mixture toxicity analysis of water contaminants with the fish embryo assay**

S. Schmidt, Helmholtz Centre for Environmental Research UFZ; W. Busch, Helmholtz centre for environmental research - UFZ / Bioanalytical Ecotoxicology; R. Altenburger, UFC Centre for Environmental Research / Department of Bioanalytical Ecotoxicology; E.K. Kuester, Helmholtz Centre for Environmental Research / Bioanalytical Ecotoxicology

The European commission stressed the need for the evaluation of mixtures in the environment (Anonymous, 2012). Nevertheless, in most cases the contaminants are regulated on a single substance basis and not as mixtures (with certain exceptions such as pesticides and PAHs, EU Water Framework Directive Nr. 2000/60/EC). As multiple contaminants with similar mode of action are in solution in the water at the same time and can have combined effects these would be underestimated by single substance evaluation only. Beside the existence of the two main concepts of concentration addition (CA) and independent action (IA), Berenbaum (1985) suggested to use CA as the universal assessment tool for joint action. This was supported amongst others by Backhaus and Faust (2012). Due to the high number of known water contaminants many substances have to be evaluated in a short amount of time. The risk evaluation can be focused on safe guarding of human health (Grummt *et al.*, 2013, WHO 2010) or the environment. One major organism group which is in the focus of environmental health indicators are fish. As an alternative to fish tests different fish embryo assays with the zebrafish embryo as a prominent representative is used more and more frequently. The aims of this study were: 1. to test the sensitivity of zebrafish embryos to drinking water contaminants and to see whether and which sublethal endpoints can be observed in addition to lethal endpoints and 2. to analyze which concept of mixture design can predict the toxic effects accurately when using mixtures of drinking water contaminants from dissimilar chemical classes (e.g. pharmaceutical, pesticide etc.). Four substances were tested for their toxic effects to the zebrafish embryo after 96 h of exposure: a pharmaceutical (Carbamazepine), a fungicide (Carbendazim), a precursor of industrial products (2,4- Dinitrotoluene) and an aromatic compound (2-Amino-9H-pyridol[2,3]indol). Observed effects were lethality, hatching inhibition & hypo-pigmentation. Follow up mixture tests were based on the LC or EC<sub>50</sub> dilution using a single endpoint as observation parameter. Results showed that from the four substances tested the three which had lethal and sublethal effects did act mainly concentration additive. Therefore, in a worst case scenario substance effects to fish embryos were at maximum only prone to overestimation when using CA as the sole mixture concept. The use of IA would have underestimated all effects.

#### **MO104**

##### **Modelling target gene expression profiles in zebrafish *Danio rerio* exposed to *Microcystis aeruginosa* and the toxin microcystin-LR**

D.A. Sabrei, School of Life Sciences; C.H. Redshaw, European Centre for Environment and Human Health and University of Plymouth / School of Geography Earth and Environmental Sciences; A.J. Moody, University of Plymouth; T.B. Henry, Heriot-Watt University / School of Life Sciences

*Microcystis aeruginosa* is a cyanobacterium that can produce the hepatotoxin

microcystin-LR (MC-LR) and that is responsible for many harmful algal blooms (HABs) in freshwater. Blooms of *M. aeruginosa* frequently occur in eutrophic surface waters, and the presence of the cyanobacteria and toxins can become an important problem for ecological and human health. We have found that toxicity in the zebrafish *Danio rerio* includes effects that are independent of the toxin. Our objectives are to investigate changes in target gene expression profiles in zebrafish in relation to concentration and duration of exposure to *M. aeruginosa* and MC-LR. We have cultured a toxin-producing strain and a non-toxin-producing strain of *M. aeruginosa* to generate a supply of lyophilized cyanobacterial cells characterized for use in toxicity tests. Zebrafish larvae (age 72 h post fertilization) will be exposed to lyophilized *M. aeruginosa* or MC-LR at MC-LR concentrations of (5, 25, 50 µg/L) and fish will be sampled after different exposure durations (2, 4, 8, 24, 48 h). Larval survival will be recorded and changes in expression of target genes will be investigated by quantitative PCR for the following genes: catalase (*CAT*), superoxide dismutase (*SOD*), glutathione peroxidase (*GPx*), glutathione reductase (*GR*), glutathione-S-transferase (*GST*), protein phosphatase (*PPI*, *PP2A*), and cytochrome P450 (*CYP1A*). We anticipate that these results will enhance understanding of the molecular responses of fish during the progression of an exposure to a HAB caused by *M. aeruginosa*.

## MO105

### Effects of uptake of Copper Nitrate Trihydrate on zebrafish (*Danio rerio*) early-life stages

K.F. Silva; A.J. Nogueira, University of Aveiro / Department of Biology CESAM; A. Val, Instituto Nacional de Pesquisas da Amazonia INPA

Climatic change studies have highlighted the importance of including environmental factors as potential additional stressors to aquatic life. Changes in climate and hydrological extremes have been observed in the last fifty years while projections of climate models raise special concern for large areas of tropical regions principally in developing countries. The Amazon Basin holds the greatest diversity of fish in the world, and their distribution across the myriad of habitats in the Amazon region is defined by the complex organism-environment interactions. In the Amazon region there are major sources of pollution due to anthropogenic activities, namely associated with high concentrations of metals reaching water bodies. Metal ions contamination are a major source of concern around the world. Copper is essential to fish but can be toxic in high concentrations thus, due to its abundance on earth, it is a metal that can contaminate the environment. It is known to cause toxic effects in aquatic organisms although risks to tropical fish are not well known. The objective of this study is to evaluate the acute toxicity of Copper ions to zebrafish early life stages and quantify biochemical biomarkers (GST, LDH and CHE) as indicators of exposure to these Metal. The exposures were conducted following the OECD's protocol for the Fish Embryo Toxicity (FET) Test (OECD, 2006). To determine the toxicity of metal for early-life stages of zebrafish the following treatments were used: 0 (control), 0,038, 0,06, 0,095, 0,15, 0,24 and 0,38 mg L<sup>-1</sup> of copper in water (prepared as copper nitrate solutions). Biomarkers' activities (GST, AChE and LDH) were measured in early-life stages after exposure to concentrations of Copper corresponding to the LC1, LC2, LC5 and LC10. The lethal concentration for 50% of the population after 96 hours of exposure (LC<sub>50-96h</sub>) was calculated with the help of ToxCalcMix spreadsheet running under Microsoft Excel software. One-Way ANOVA test was used for data analysis of enzyme activity with SigmaPlot 11.0. LC<sub>50-96h</sub> for the zebrafish early-life stages. It can be concluded that acute toxicity data obtained from zebrafish indicated sensitivity to these organisms. The parameters assessed in this study will contribute to the understanding of the mechanisms of action and toxicity of copper in *Danio rerio*.

## MO106

### Morpho-functional and transcriptional response of zebrafish retinal cells to cadmium stress

R. Scudiero, Department of Biology; R. Panzuto, Biologia; M.G. Esposito, University Federico II of Naples; P. Simoniello, GSI Helmholtz Center for Heavy Ion Research / Department of Biophysics; B. Avallone, University Federico II of Naples; C.M. Motta, University Federico II of Naples / Department of Biology Ocular malformations are observed in embryos and adults of aquatic species after exposure to toxicants. In this study, cadmium, a chemical stressor, was used to determine the toxic effects on the retinal development and visual ability of adult zebrafish (*Danio rerio*). Our results demonstrated that Cd-exposure (100 µM) from sphere (4 hpf) to gastrula stage (8hpf) led to the up-regulation of the expression of *lambda1-crystallin* and *Retinoblastoma Binding Protein 6* transcripts in embryos. Cry11 is a lens protein that acts as a molecular chaperone; Rbbp6 is a protein regulating cellular proliferation. *In situ* hybridization demonstrated that Cd induced the up-regulation of these genes also in adult retina, in the inner and outer nuclear layers. The Cd-induced over-expression was dose-dependent and reversible. Interestingly, metallothionein, the cysteine-rich, low molecular mass metal-binding protein considered a key molecule involved in cellular protection against toxic metals, did not seem to be up-regulated. Adult retinal morpho-cytological alterations were investigated by light and electron microscopy, while the functionality of Cd-exposed retina was assessed by re-illumination behavioral tests. After Cd-treatment, dose-dependent alterations were clearly observed. The nerve fiber layer was clearly thickened and vacuolated, several ganglion cells had compact pycnotic nuclei. Changes occurred in the thickness of the pigmented epithelium and at the level of the cones inner segments. TEM observations of

Cd-treated retina showed ganglion cells with highly vacuolated cytoplasm and cells with ultrastructural apoptotic features. Apoptotic cells were also evident in the inner nuclear and in the photoreceptor layers. Many polymorphic Müller cells were observed both in inner and outer nuclear layers. Behavioral tests demonstrated that re-illumination with white or colored light induced a significant escape response after Cd-treatment, not observed in untreated animals. All together, data demonstrated that Cd toxicity caused: 1) dysregulation of gene expression; 2) degeneration and loss of organization at both macro and microscopic levels; 3) impairment of the functional response, particularly through increased light sensitivity. The increased amount of Müller cells with irregular shape suggested that the recovery of visual acuity is due to a regenerative process involving these retinal macroglial cells, that are able to dedifferentiate and function as neural stem cells.

## MO107

### Sublethal toxic effects of first- and second-generation antihistamine in *Danio rerio* for a tentative environmental risk assessment

K. Kroll, Univ. of applied sciences Northwestern Switzerland; A.K. Zenker, University of Appl. Sc. Northwestern Switzerland / Institute of Ecopreneurship Histamine antagonists were developed over 80 years ago. They inhibit the action of histamine by blocking to the receptor. There could be also an inhibition on the transformation of histidine to histamine. Histamine is known for its role in allergic reactions and their symptoms. In total there are up to 30% of the Swiss and 2,3 % of the European population having trouble with hay fever or other allergies. In total there are 2,4 million people in Switzerland and over 17 million people in Europe suffering from allergy and more people affected by allergies are expected in the future. All of them are forced to use antihistamine, whereby high consumption rates of these pharmaceuticals could pose a threat to the environment. For example after ingestion 70% of Cetirizine is not metabolised in the human body, is then excreted and will enter surface water via treated wastewater. Today there are only a few tests available to study the risk of second-generation antihistamine. In this study we wanted to know whether only the pharmacological effects of second generation antihistamine were improved or also their impact to the environmental compared to first generation drugs. Since first-generation antihistamines are responsible for many side-effects like increasing heart rate or fatigue, we tested in this study the first-generation antihistamine diphenhydramine and the often used second-generation antihistamine cetirizine. The *Danio rerio* embryo toxicity test was used and expanded to 144 hpf. Organs under investigation were liver, heart, otic vesicle, swim bladder, eyes, lateral fin, trunk, belly and other visible changes like blood circulation, spontaneous movement, heartbeat and early hatching. Based on our results, the second-generation antihistamines have less toxicological effect than the first-generation antihistamine. In *Danio rerio* Diphenhydramine had an LOEC of 15 µM in comparison to Cetirizine with an LOEC of 1000 µM. Toxicity is a factor of 66,7 higher. A noticeable difference was observed in blood circulation. There was a significant effect after exposure to first-generation antihistamine Diphenhydramine after 48 hpf at 120 µM. The second-generation antihistamine Cetirizine had no effect even at 2 mM. Calculated with an safety factor of 400 the risk characterisation ratio of Diphenhydramine was 1,22 and 0,13 for Cetirizine. For the calculated environmental risk, Diphenhydramine was 9,48 times higher compared to Cetirizine.

There is strong evidence that the use of pesticides has major impacts in non-target wildlife with serious consequences to aquatic ecosystems. Typically environmental concentrations of pesticides rarely cause lethality; therefore the risk assessment of these chemicals is better achieved if a battery of sublethal endpoints is used. Within this context, the main goals of this work are to evaluate the effects of Carbaryl – a carbamate insecticide – and Carbendazim – a benzimidazole carbamate fungicide – in zebrafish embryo development, biochemical markers and behaviour. Developmental endpoints included delay, hatching success, edemas, malformations, reduction of size, consumption of yolk sac and alterations in heartbeat rate) while the biochemical markers evaluated were cholinesterase, glutathione-S-transferase, lactate dehydrogenase and catalase. The behaviour was assessed through a locomotion assay at 120 hours post fertilization using the Zebrafish (Viewpoint, France) video tracking system. Zebrafish embryos showed to be very sensitive to both pesticides. For Carbaryl a 96h-LC50 of 14.94 mg/L was calculated. At the sublethal level, carbaryl significantly affects heart beat rate, reduced body length and increased incidence of edema and malformations in concentrations where no mortality was detected. Carbendazim also showed high toxicity with a 96h-LC50 of 1.75 mg/L while sublethal effects such as hatching success, edemas, malformations, reduction of heartbeat, body length and yolk sac consumption were observed. Preliminary data suggested that carbaryl and carbendazim are detrimental for embryonic development and teratogenic by causing a series of developmental defects at non-lethal concentrations which may also compromise zebrafish long term survival. This study highlights the importance

of considering the sublethal effects of environmental contaminants in risk assessment in order to better estimate long term effects of contaminants in aquatic ecosystems.
